HIPPOCAMPAL DAMAGE IN AMNESIA PATIENTS

MICROSCOPY
product review

METTLER PM with Application Pacs
Consider it a species that adapts to your natural habitat.

One usually doesn't start out in life pre-
pared for everything the future may hol
But for a METTLER PM precision balanc
that's a normal state of being.
The capacity to change and evolve into
a higher order is built into the METTLER
PM from inception. So no matter what
you need a balance to do to keep up w
your changing needs, you won't be
disappointed.
Besides inheriting METTLER's tradition
for quality, the PM offers a long line of
options, Pacs and peripherals that mak
it everything you ever wanted your bal-
ance to be.
In fact, the METTLER PM balance is so
intrinsically flexible, it could make all
other balances an endangered specie
Call us for information and make a
change for the better.

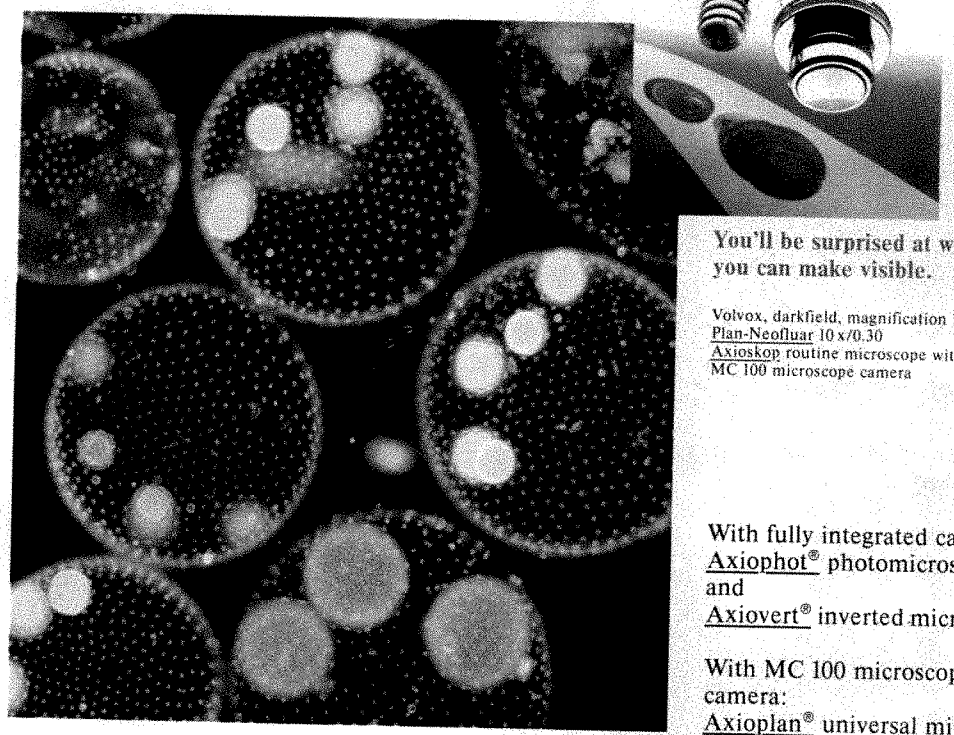
Reader Service No.292



CU12-Ho 6848-321-P36672

For 117 years, Carl Zeiss has been "The Great Name in Optics". The tradition continues with the best microscope optics ever.

FOR THE ULTIMATE PERFORMANCE IN PHOTOMICROGRAPHY. ICS OPTICS FROM CARL ZEISS.

321

CS optics (Infinity Color-Corrected System) are an advanced eries of newly calculated, highly corrected microscope objec- ives with infinite image distance. But there is more. ICS ptics are integrated into the new series of Zeiss microscopes s fully optimized systems. From the light source to the objec- ives, eyepieces and camera – everything is in perfect har- nony. That is what makes the ifference between ICS optics nd other optical systems, d what guarantees a new mension in flawless photo- icrography.

You'll be surprised at what you can make visible.

Volvox, darkfield, magnification 100 : 1, Plan-Neofluar 10 x/0.30 Axioskop routine microscope with MC 100 microscope camera

lliant photographs – high ıtrast and high resolution

e Planapochromat and Plan-Neofluar ICS objectives pro- ide excellent image quality in hotomicrography. The inter- mediate image is fully correct- ed due to the unique Zeiss patented objective and tube lens combination. Sharp, crisp, absolutely flat images over the wide field of view of 25.

Camera projection lenses, corrected for the full spectrum of color films, transfer this igh image quality to the film.

0% of light for the film

he fully integrated cameras of the photomicroscopes Axiophot and Axiovert com- plement the superb perfor- mance of the ICS optics. 90% of the light is used on the film. The result: short expo- sure times, particulary impor- tant for fluorescence.

Spot measurement con- centrates the exposure on the most important specimen detail. Illuminated reticles, adjustable to the brightness of the background, simplify focusing. Focused-in scale bars facilitate documentation.

For every application in photomicrography, the new series of Zeiss microscopes with ICS optics will surprise even the most demanding microscopists.

With fully integrated camera:
Axiophot® photomicroscope and
Axiovert® inverted microscopes.

With MC 100 microscope camera:
Axioplan® universal micro- scope
Axioskop® more-than-routine microscope and
Axiotron® inspection micro- scope for the semiconductor industry.

For complete details, please contact Carl Zeiss.

KOMBISTEREO

FOR A TOTALLY NEW VIEW OF THINGS

Escherichia coli
transmitted light
18:1 and 180:1

COMBINED STEREOMICROSCOPE AND MICROSCOPE

Now there's a single instrument that lets you see objects three-dimensionally at from 6.4× to 90× magnification and two-dimensionally from 64× to 600×. An instrument that leaves you a lot of space for easy manipulation of the object.

The Wild KOMBISTEREO™ combines a stereo-microscope with a microscope. It has a stereo objective for generous working distance, large field, and outstanding depth of field, and a microscope objective for instant detail analysis without the need to change instruments.

Ask today for details of the KOMBISTEREO.

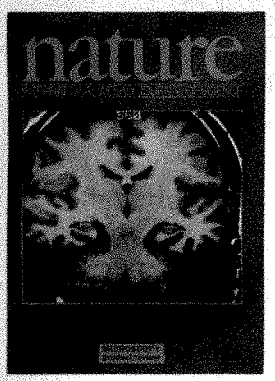
Safety by design

New packaging for ^{32}P-nucleotides

Amersham introduces new packaging for its range of ^{32}P-labelled nucleotides. The new custom designed container (CDC) has been designed in response to customer feedback and achieves the two most important features, *optimum safety* and *ease of use*.

- **Improved shielding** – The new CDC contains both lead and transparent plastic to provide comprehensive shielding.
- **Easy access** – The new container can be opened easily by merely unscrewing the tightly sealed lid.
- **Convenient handling** – The inner vial can be transferred to other specially designed, transparent containers for ease of pipetting while completely shielding the user from β-radiation.
- **Rapid thawing** – By transferring the inner vial to the specially designed holder or workstation, thawing times are reduced by more than half.



For further information about the new packaging and the full range of Amersham's labelled nucleotides, contact your Amersham representative or your local Amersham office.

◀ The normal hippocampus imaged by a new magnetic resonance technique, which reveals damage in the region in patients with severe amnesia. This underlines the importance of the hippocampus in memory, and may have diagnostic applications. See page 54.

THIS WEEK

Fossil furore

Professor V. J. Gupta of the Centre of Advanced Study in Geology, Panjab University, pleads innocent to the serious allegations of wrong-doing published in *Nature* earlier this year. But articles by four co-authors of questionable papers, including two close colleagues at Panjab University, raise further disturbing questions. Commentary, pages 11-16.

Pine as pollution monitor

Traces of environmental contaminants such as DDT and other organochlorine compounds accumulate in the waxy coating of pine needles. Erikson *et al.* on page 42 suggest that measurements of these compounds in the needles can be used as indicators of past and present atmospheric pollution.

Powerful connections

A comparison of the ability of monkeys to perform a perceptual discrimination task with the behaviour of a single neuron of the visual cortex shows that a single neuron can 'perform' as effectively as the whole animals. Psychophysical judgements, therefore, could be based on the activity of a small number of neurons. Pages 52 and 20.

Dopey conductors

Substitution of calcium for yttrium in the high-temperature superconductor $YBa_2Cu_4O_8$ ('124') raises the critical temperature by about 10 degrees to 90 K, on a par with that of $YBa_2Cu_3O_7$ ('123') and safely in the range accessible by liquid-nitrogen cooling. The 124 superconductor has physical properties more conducive to practical applications than the 123 compounds, so 'calcium doping' may bring a practical high-temperature superconductor a step nearer. Page 41.

Galaxies in focus

Gravitational lensing of powerful distant quasars by intervening galaxies provides astronomers with important information about the structure of the 'lensing' galaxies. If the gravitational lenses are moving, however, additional 'diagnostic' tests will be possible. Page 38.

Organizing the embryo

Peptide growth factors that induce the embryonic organizing properties of embryonic mesoderm differentially induce different levels of the homoeogene *xhox3*, whose graded distribution is a marker for antero-posterior position on the embyonic axis. Article, page 33.

Whalemeat again?

The organic-rich remains of whales on the sea floor may act as 'stepping stones' for marine faunas that rely on reduced energy sources such as sulphides,

perhaps contributing to dispersion of animals adapted to life near hydrothermal vents. Page 27.

Controlling the heart

Cloning and expression of second type of human atrial natriuretic peptide receptor (ANP-B) shows that whereas ANP-A receptor responds similarly to human ANP and porcine brain natriuretic peptide, ANP-B is preferentially activated by the latter. This may have important implications for the control of cardiovascular homoeostatis. Page 68.

Stop Your Blues With The DyeTector™ 100.

The DyeTector™ 100 is an automatic electrophoresis shut-off apparatus. No longer worry about electrophoresing your valuable DNA samples into the buffer chamber. The DyeTector™ 100 is designed to turn off your power supply when the formulated blue loading dye migrates beneath the sensor.

Never worry again about electrophoresing your samples the wrong distance. The DyeTector™ 100 eliminates all the guess work. The DyeTector™ 100 enables you to electrophorese gels overnight and have the samples migrate to the exact position of your choice. The DyeTector™ 100 is also ideal for fast mini gel runs.

Also Available With Mini Horizontal Gel Box.

The DyeTector™ 100 is simple to use and is available with two models of Stratagene's electophoresis gel tanks (internal: 88mmL × 75mmW × 48mmH-for mini horizontal and 200mmL × 200mmW × 95mmH for large box). Please contact Stratagene's technical services for more information about our full line of products.

Superior Service And Quality Peptides Are Easy To Spot.

Spotting quality peptides is easy if you focus on the right source - Bachem Inc. Our peptides of peak purity and biological activity are at prices that will bring you back to us time and again.

Bachem provides the superior service and technical support your research demands. Fast delivery, assistance in meeting FDA requirements, prompt custom synthesis, and competitive bulk price quotations are all available from our technical and customer service staff who are ready to help.

Every day we address your critical need for the timely introduction of new peptides. The result is the widest selection of the most up-to-date synthetic and recombinant products including:

- Human Defensin HNP-2
- Endothelins
- Urodilatin
- Recombinant EGF, TNF, Il-2 and Il-6
- New resins and reagents for peptide synthesis

Why look any further when Bachem provides uncompromising quality and service at such competitive prices? Call us today to obtain a copy of our catalog or for detailed information on any of our products.

Then set your sights on successful research.

SAPPHIRE

all image processors are not the same

and noise reduction is only part of the story

Most systems available today begin with noise reduction – and that's where the image processing ends.

Now Sapphire takes over, with analogue gamma correction to optimise the input signal: with unique **Real-time** digital shading correction and with histogram equalisation facilities, compensating for uneven illumination or high profile subjects. **And** it has the most rapid and sophisticated noise reduction in the business.

It's not simply a pursuit of clever processing which defines Sapphire, but cool headed economic performance. The new shading-correction capability alone significantly extends the useful life of camera and intensifier by compensating for wear.

Just one of the ways that Sapphire pays for itself, time and again.

Sapphire deserves a closer look – call us now for the full picture or use the reply number for rapid response.

One More Reason The ACAS 570 is...

The Cytometer for All Reasons

Reason #1 — Interactive Laser Cytometry

You command the power of the laser for new research capabilities such as sorting rare cells for cloning, fluorescence photobleaching, photoactivation, and cellular microsurgery.

Reason #2 — Quantitative Fluorescence Measurements

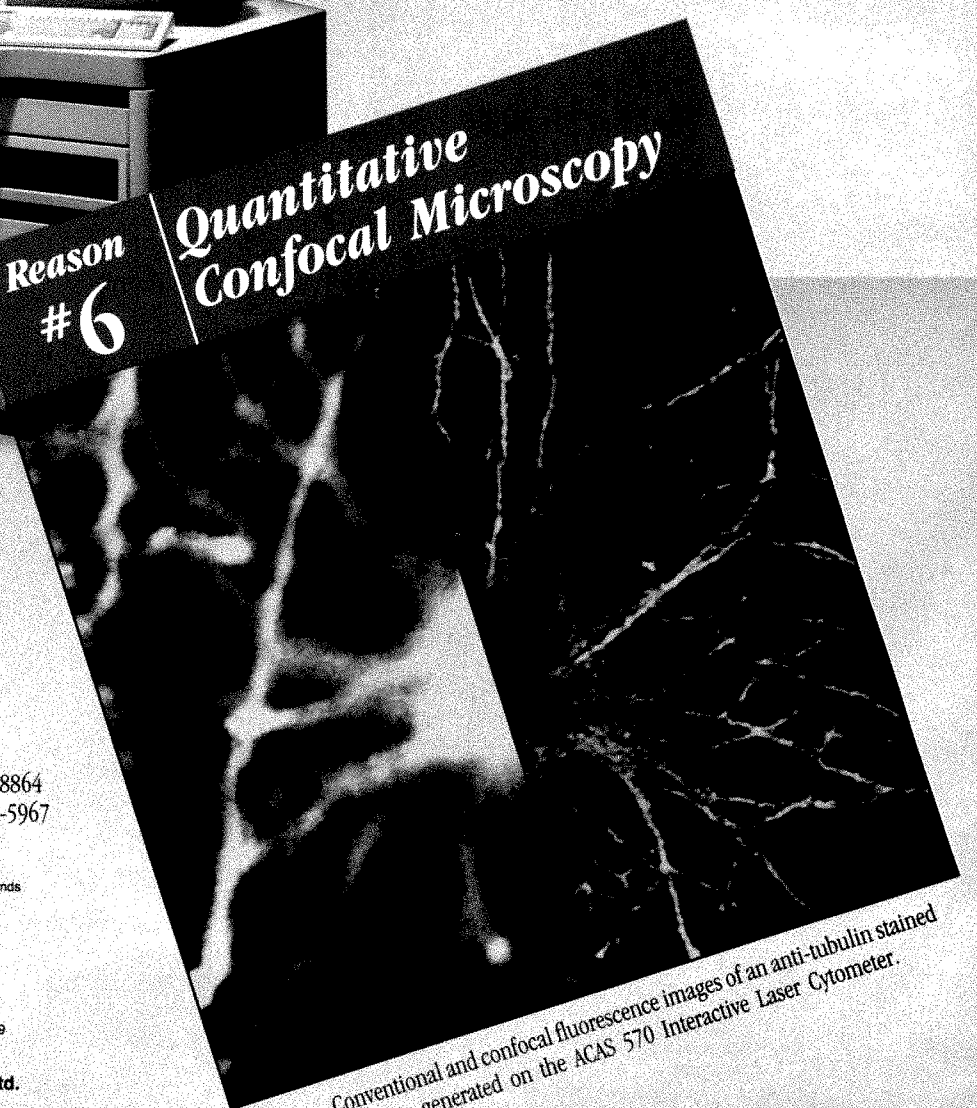
From single to dual label fluorescence measurements, you get **real numbers** for fluorescence quantitation ranging from cell-cell communication and molecular diffusion, to intracellular Ca^{2+} and pH.

Reason #3 — Sensitive Fluorescence Measurements

Advanced photometric detection and a focused laser spot give you reliable data from live cells with minimal photobleaching, and without the need for signal averaging.

Reason #4 — Comprehensive, Interactive Software

Powerful software teams laser cytometry with advanced computer technology — giving you integrated data acquisition, analysis, and management functions that are easy to learn, and easy to use. You also get a powerful assortment of application based programs specifically designed for the cell biologist.



Reason #5 — Versatile Integrated Instrumentation

From fluorescence imaging and cell cloning, to measuring transient Ca^{2+} and pH, the ACAS 570 provides the broadest range of cell and molecular biology applications available in a single instrument.

And now... the ACAS 570 gives you the exceptional resolution and contrast of confocal imaging.

Reason #6 — Quantitative Confocal Microscopy

Conventional and confocal fluorescence images of an anti-tubulin stained astrocyte generated on the ACAS 570 Interactive Laser Cytometer.

ESSENTIAL TO PROGRESS • ESSENTIAL TO PROGRESS • ESSENTIAL TO PROGRES

What in the world are you looking for?

In many fields of science and technology, people have learned to trust the quality and consistency of our products and services.

High-purity chemicals and reagents produced by BDH are a vital safeguard for the accuracy of work by those involved in advanced research and routine analysis alike.

The famous BDH AnalaR range of chemicals and reagents is recognised internationally: exceptional standards of purity are assured through our sophisticated production procedures, quality control and advanced testing techniques, which include inductively-coupled plasma emission spectroscopy.

New electrophoresis reagents have been introduced and a special range created for molecular biologists.

But while high-purity chemicals are a strong suit of BDH Limited we have other areas of specialisation – as you can see here.

These, too, can involve provision of modern materials, tools and products giving assistance to those involved in advanced analytical work, environmental testing, and scientific investigation at the frontiers of human knowledge.

BDH is a supply source for almost every kind of laboratory equipment. Our Advanced Materials Division produces monocrystals used for particle detection in high energy physics projects investigating the structure of the atom. We supply test systems to warn of pollution or unsafe inclusions in drinking water, rivers and reservoirs. Medical laboratories and hospitals are supplied with diagnostic materials and equipment, including those to aid early diagnosis of cancer, thereby assisting effective treatment and cure.

So BDH is a company that may well have exactly what you're looking for.

BDH Limited, Broom Road, Poole, Dorset BH12 4NN, England. Tel: (0202) 745520 Fax: (0202) 738299. Telex: 41186 or 418123 TETRA G.

Repligen IPA-300: The Protein A that can cut development time

Repligen provides ultrapure and immobilized rProtein A with complete documentation on file with the FDA and full support from our experienced staff of regulatory affairs specialists. This means that you lose less time substantiating your materials and complete your IND submission faster. Plus IPA-300 guarantees high binding and virtually no leakage to the toughest specifications in the industry. So for the consistent purity you need for single pass purification of therapeutic grade monoclonal antibodies, specify Repligen's IPA-300. Whether it's 2 milliliters or 2 liters, we'll ship in one business day. Cut through the paperwork. Call us today.*

Is your Protein Research on Track?

Electrophoresis with Titan® III cellulose acetate is a fast, inexpensive method for monitoring protein research. Separations are complete in minutes and cost just pennies per sample.

Titan III tells you quickly...

- Identity
- Purity
- Binding properties
- Approximate concentrations

Cellulose acetate electrophoresis is flexible, technically simple and requires tiny sample volumes. Migration is fast — only minutes to separate and stain. Patterns may be enhanced by general staining, immunofixation, transfer to nitrocellulose, autoradiography or many other techniques.

About Titan III Cellulose Acetate

- Available in several convenient sizes
- Indefinite shelf life
- Requires very little storage space
- Stable at room temperature

Other Applications for Researchers

- Monitoring column chromatography elutions
- Evaluation of samples in protein purification experiments
- Monitoring the progress of protein digestion by tryptic agents
- Assessing contents of cell extracts

For more information and details about packaging and pricing, call toll free 800-231-5663.

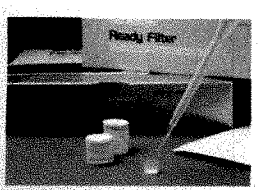
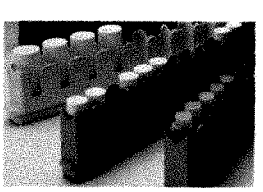
The Counter Solution

Liquid Scintillation Counting Will Never be the Same.



Announcing an unprecedented breakthrough in the three elements of scintillation counting:



- Superior Sample Preparation Supplies
- Innovative Instrumentation
- Powerful Data Handling Software

The Counter Solution from Beckman.

Take the liquid out of liquid scintillation. Count your samples dry with Ready Filter™ and Ready Cap.™ Coated with Xtalscint™ solid scintillation medium, simply apply your sample, dry and count. Safer to use than traditional liquid cocktails.

Place your samples in our new LS 6000 Series instruments and walk away. Accurate DPM without quench curves. Plus unique solutions for accurate counting of colored samples, correction of luminescing samples, and faster analysis of low activity samples.

Data compatibility with virtually any software program. With three ways to load your data into a personal computer and four ways to convert it into different formats, you can analyze your findings with the software of your choice.

Put **The Counter Solution** to work in your laboratory today by calling 1-800-742-2345 (U.S.) or contact your local Beckman representative.

The DNA DIPSTICK™

Makes Quantification Fast & Simple!

Invitrogen Introduces a Fast, Simple, Non Radioactive Method For Quantification of Nucleic Acids with The DNA DIPSTICK.

- Quantitates Nucleic Acids at Concentrations as Low as one Nanogram per Microliter
- Provides a Permanent Record of Results
- Is More Consistent Than Conventional Techniques
- Requires no Special Equipment for Fast Inexpensive Results
- Ideal for Quantification of single or double stranded DNA, RNA or oligonucleotides

Quantification Doesn't Get any Easier

Now you can have fast, accurate nucleic acid measurements which are critical for PCR Amplification, Subcloning, DNA sequencing, and cDNA or Genomic DNA Library Construction.

Because time and accuracy are very important in today's rapidly changing world, Invitrogen is committed to providing DNA Technology that is as advanced as it is simple.

To order, ask for catalog #K5632-01.

"How can I reduce the amount of time I spend on sample preparation while doing simple screening and quantitative binding studies? And what about disposal?"

The Counter Solution

Switch to Ready Filter.™ Available in 25 mm circles or sheets for harvesters. Filter the samples, dry, and count—without cocktail. And Ready Filter is disposed of as dry waste, so it saves you money and is environmentally safe.

The LS 6000IC with Xtalscint™ CPM/DPM provides the most efficient counting of solid scintillating samples. The result is higher throughput and more accurate results.

Analyze data using AccuFit™ Saturation Two-Site or AccuFit™ Competition software. Both use non-linear fitting techniques analyzing one- or two-site receptors.

The Counter Solution for your binding studies. Call 1-800-742-2345 (U.S.) or contact your local Beckman representative.

Humors, Hormones and The Mind

BERNARD DONOVAN

An approach to the Understanding of Behaviour

Brain science is passing through a revolution, with the progress in recent years being remarkable. The new knowledge is of major practical impact in helping us understand the way we behave and in providing new methods for the treatment of mental illness.

Much of this new material is highly complex and difficult to comprehend. This volume sets out to convey the interest and excitement of recent findings in a manner understandable to a wide cross-section of medical and non-medical workers.

Contents

Preface
INTRODUCTION
1 Humours, Humors and Hormones
2 The Neural Basis of Humoral Action
HUMORS
3 Neurohumors
4 Hormonal Humors
5 The Master Humors
6 Peptide Humors
7 Immunohumors
HOW THE HUMORS AFFECT THE MIND
8 Senses
9 Emotion
10 Stress
11 Aggression
12 Learning and Memory
13 Eating and Drinking
14 Masculinity
15 Femininity
16 Intellect
17 Personality

"I need to use as much sample as possible with a low background counter for low activity samples. Sometimes I also need a copy of the sample spectrum."

The Counter Solution

- Use Ready Gel™ for stability, even at 50% sample load. With minimum luminescence you get accurate results in less time.
- The LS 6000LL comes with luminescence correction and a two-phase monitor ensuring that samples remain in a stable gel. The background is less than 50% compared to conventional systems for accurate analyses of low activity samples.
- Store isotope spectra on a PC using Data Capture software. Review the spectra by using Data Capture Support or MPG software.

The Counter Solution for your environmental studies. Call 1-800-742-2345 (U.S.) or contact your local Beckman representative.

GENE MANIPULATION IN BIOLOGY AND HUMAN DISEASE

9–10 November, Before the Cold Spring Harbor Meeting

BOOK NOW WHILE PLACES REMAIN

How readily can the genes responsible for predisposition to conditions such as ischaemic heart disease or schizophrenia be identified? What are the prospects of human gene therapy? Are transgenic animals the key to understanding the precise genetic control of development? How much more sophisticated can methods of genetic manipulation and gene identification become?

These are among the major questions that will be addressed by the distinguished speakers at Nature's 1989 conference. A chairman will outline the context and aims of each session, the speakers will review their area of expertise and report the latest advances, and a rapporteur will draw out the implications of each session. There will be a panel discussion of the ethical and legal problems raised by human gene research and therapy. For the convenience of delegates, the second day of the conference will finish in mid-afternoon, whereas the first day will be extended by the panel session followed by a wine and cheese reception.

We expect the conference to sell out well before opening, so urge you to make sure of your place now by returning the form below.

CONFERENCE SESSIONS

1 HUMAN GENETIC DISEASE

James Crow, U. of Wisconsin (chairman)
Louis Kunkel, Harvard Medical School
Gerd Utermann, University of Innsbruck
Kenneth Kidd, Yale University
Eric Lander, Whitehead Institute (rapporteur)

2 PROSPECTS FOR GENE THERAPY

Leon Rosenberg, Yale (chairman)
Irving Weissman, Stanford University
Richard Mulligan, Whitehead Institute
French Anderson, NIH
David Baltimore, Whitehead (rapporteur)

3 HUMAN GENE RESEARCH: PANEL DISCUSSION

4 TRANSGENIC MOUSE MODELS

Richard Palmiter, Washington U. (chairman)
Douglas Hanahan, University of California SF
Erwin Wagner, IMP Vienna
Ron Evans, Salk Institute
Brigid Hogan, Vanderbilt U. (rapporteur)

5 GENE DISRUPTION AND DEVELOPMENT

Mario Capecchi, U. of Utah (chairman)
Fred Alt, Columbia University
Janet Rossant, University of Toronto
Peter Gruss, Max Planck Institute Gottingen
Bruce Alberts, U. of California SF (rapporteur)

GENE MANIPULATION IN BIOLOGY AND HUMAN DISEASE: 9–10 November 1989

REGISTRATION FEES
Standard rate including reception

Special rate for full-time academics and government employees only $300

Sponsor's liability: should the conference be cancelled or postponed for any reason, the sponsor's liability is limited to the return of the registration fee. Cancellation policy: all cancellations must be received in writing. Cancellations before 30 August will be subject to $25 service charge. No refunds will be made after that date. Registrants unable to attend may send a substitute.

Genetically Engineered Human Therapeutic Drugs

D. Copsey and S.Y.J. Delnatte, Pantech Partners

A comprehensive reference source that provides up-to-date information on human therapeutic proteins in a convenient, logically organized format. Divided into two parts, this book provides detailed, accurate reviews of the status and development of drugs under development as well as launched products and products in clinical trials. Organized by generic product group, this work provides up-to-date product evaluation and reliable information based on published research findings.

October 1988, 670 pp.,

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously

Nature is an international journal covering all the sciences Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields Please write clearly and simply, avoiding unnecessary technical terminology *Nature*'s staff will edit manuscripts to those ends if necessary Contributors should check their proofs carefully

Because of the competition for space, many of the papers submitted for publication cannot be accepted For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words

CATEGORIES OF PAPER

Review Articles survey recent developments in a field Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator Length is negotiable in advance but must not exceed six pages of *Nature*

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications

Articles may contain a few subheadings of two or three words The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows There should be fewer than 50 references

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature* The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study Letters should not have subheadings or more than 30 references

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research Some are commissioned, most are unsolicited They are normally between one and four pages of *Nature* in length.

News and Views articles are intended to inform non-specialist readers about a recently published advance Suggestions should be made to the News and Views Editor. Illustrations are welcome Proposals for meeting reports should be agreed in advance

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature* Priority is given to contributions of less than 500 words and five references Figures are welcome

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only Four copies are required, each accompanied by lettered artwork Four copies of half-tones should be included Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number Original artwork should be unlettered Ideally, no figure should be larger than 28 by 22 cm Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published

Colour Artwork. A charge of £500 a page is made for 4-colour figures Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible The figure should be described first, then, briefly, the method Reference to a method described elsewhere is preferable to a full description Methods should not be described in detail in the text

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate) Text should not be included in the reference list References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65) The first and last page numbers should be cited Reference to books should clearly indicate the publisher and the date and place of publication

Abbreviations, symbols, units and Greek letters should be identified the first time they are used Acronyms should be avoided as much as possible and, when used, defined Editors will shorten words if necessary In case of doubt, SI units should be used

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named.

Acknowledgements should be brief Grant numbers and contribution numbers are not allowed

Submission. *All manuscripts may be submitted to either London or Washington They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT)*

NATURE VOL 341 nature 7 SEPTEMBER 1989

Bush declares war on drugs

This week's strategy for saving the United States from a new wave of drug dependency may create a sense that something is being done, but the real war will have to be won by different means.

PRESIDENT George Bush is nothing if not transparent. His declaration of war on narcotic drugs this week is what his electors have been looking for. There are three categories of people in the United States pleading for "tougher" action on drugs: middle-class parents fearing their children will be hooked, poor people in the city ghettos whose families and communities are being destroyed by the drug traffic and the generality of those who believe that the law is the law, and must be strictly enforced. This week's package will bring temporary comfort to them all, but will solve few of the problems that matter.

The one obvious exception is the administration's swift decision to provide the government of Colombia with military assistance to resist the outrageous anarchic ambitions of those called the drug barons, who control the cocaine trade. It will strengthen the reputation of the United States throughout Latin America if it is seen to be ready to help governments so seized of the danger that their constitutional foundations will be undermined that they appeal for assistance, as Colombia did two weeks ago. (Nicaragua is, or was, another matter.)

The social damage done by drugs in the United States has two aspects: that caused by narcotic addiction (or even by routine use) and that caused by the traffic. Bush plans to deal with both punitively. There will be tougher penalties for those convicted of selling or handling narcotics (and more people to help find them), and tougher penalties for those found using illegal narcotics. Coca-growing countries in Latin America will come under greater pressure from the United States to persuade their farmers to grow other crops, just as farmers in Turkey and Thailand a decade ago were being urged not to grow opium poppies.

Prohibition

The obvious weakness in this strategy is that attempts to prevent narcotics reaching the United States cannot reduce the supply to zero, just as the Strategic Defense Initiative cannot realistically be designed to destroy every single hostile missile. Will the success of the supply-side proposals be measured by the increase of street prices, which presumably will mean that fewer addicts will have to steal more cash to get their fixes? The attempt to frighten off drug users by devices such as the withdrawal of driving licences (whose constitutional legality is dubious) may work with some, but not in the city ghettos. No wonder that comparisons with the fruitless war against alcohol in the 1920s, under the label of Prohibition, have been commmonplace in the past few weeks.

But what else can be done? The administration's dilemma is admittedly forbidding. Taking a leaf out of the Prohibition book and decriminalizing narcotics would at this stage do much more harm than good, yet in the long run, that is what even United States government will have to come to. Given the sheer diversity of narcotics and the ease with which new materials can be synthesized if products based on agriculture dry up, punitive regulation cannot ultimately succeed. One obvious benefit of eventual legalization is that, by taxation, the financial beneficiaries are not distant drug barons, but governments which, if sympathetic, can use the funds they collect to help drug users and especially addicts overcome their difficulties. By the same stroke of the pen, organized crime is weakened. And would not a society in which narcotics were accessible that did not destroy itself by addiction be a stronger society, and perhaps even "kinder and gentler" as well?

Desolation

The most disappointing feature of the Bush proposals is that they do very little to point towards that goal. Drug dependency is probably always a consequence of personal desolation, the causes of which are plain among the poverty-stricken of the city ghettos. (The middle classes have subtle ways of concealing discontent.) Education and jobs, or some hope thereof, would help in the short run and are a precondition of decriminalizing the narcotics business. Sadly, in the United States, that option is denied even at the beginning of what was meant to be a presidency given over to educational improvement by, among other things, the federal budget deficit, which is but another way in which the United States collectively "takes the waiting out of wanting" — a fix of a different kind.

That is why it must be hoped that governments other than that of the United States, in Western Europe for example, will resist the pressure to which they will now be subjected to fall in with the Bush strategy as if it were a kind of extension of the doings of the North Atlantic Treaty Organization into the social field. There is nothing wrong with the hope that organized crime, national as well as international, can be beaten in its own right, while

smuggled drugs should be seized when found so long as they remain illegal. But there are many places in which the use of narcotics is still so modest that its further growth would most effectively be restrained by some system in which registered users can be licitly supplied — and given such help as there is. The British system for dealing with morphine and heroin addicts in such a way was too hastily abandoned 20 years ago when a single physician was found to be rashly over-subscribing. Paradoxically, the place to restart is with the hardest drugs, and where addiction is least prevalent. Even the United States would benefit if some government were to give that strategy a try. □

The Matthew principle

The managers of Britain's universities need devices for offsetting the attractions of successful institutions.

At the beginning of another academic year, it is natural enough that the attention researchers pay to the last research meetings of the season should be inclined to wander, but British academics are more likely to let their thoughts wander than those from elsewhere. They have a great deal on their minds, not least the outcome of the long and elaborate survey of research performance at British universities (costing about £4 million) begun by the University Grants Committee and published two weeks ago by its successor, the Universities (no apostrophe) Funding Council (UFC). The objective, as the covering letter to university vice-chancellors explains, is to "inform" them about UFC's decisions about public subvention of particular universities in next year's academic year and in the succeeding four-year period. People will be anxious to know as soon as possible not only how their own departments showed in the assessments, but also how rival departments elsewhere are rated to have performed. Their future as researchers may depend on what the figures show.

But there are few surprises. The assessment is concerned exclusively with original research, not with teaching or with unoriginal contract work for outsiders. Assessments have been carried out by panels of active academics together with a sprinkling of retired people on the basis of information supplied by university departments through their universities. UFC says that more attention has been paid to research output — publications — than in previous excercizes on a smaller scale by UFC's predecessor, but the details of how that has been done will not be arguable until the new academic year is well under way (but then there are certain to be ructions). And the result? Britain has two institutions with all-round excellence in research — Cambridge and Oxford. Some others (such as Imperial and University colleges, both part of the University of London) run them close. Then there is a solid core of civic universities (typified by Manchester) whose research performance is creditable on UFC's five-point scale. And then there are stragglers in plenty.

Academics everywhere will know the explanation — it is nothing but the working of the Matthew principle of "To him who hath shall be given...". Potentially able people naturally seek posts at universities with a reputation in research and, equally, are sought to fill them. But a university already strong in research is usually better able to provide its members with opportunities for research while its reputation inevitably rubs off on them when, for example, they apply for research grants. What UFC now plans is that the Matthew principle shall be reinforced by a system under which the universities that are already strong will be further strengthened with resources at the expense of weaker places elsewhere. There is nothing intrinsically evil in that decision; it is only equitable that strong research universities should be given the resources required to match their unavoidable overheads. But the result must be to reinforce their primacy further.

Yet UFC has (or should have) a wider interest to ensure that universities further down the pecking order have a continuing opportunity to improve their research performance and thereby, for as long as British universities must depend on public funds, their income. How will that be accomplished? Much will depend on the way in which future public subvention of universities is "informed" by this year's assessments. There will be a temptation for UFC to assert that the research output of some university departments is so meagre that they should give up trying, perhaps concentrating on teaching instead.

That would carry the Matthew principle too far and confirm today's high-fliers in their present positions for the rest of time. At the very least, UFC needs to keep back some of its funds in each of the next several years so as to back research initiatives at the now less well favoured universities. But it must also make plain its determination to help the second and even third-rate institutions become first-rate if they can. One practical objective must be to keep the system competitive. Another, more subtle, stems from the reason why many academics follow what is (in Britain) a badly paid and generally thankless profession: there is always the opportunity for research. If that should ever disappear, many of the universities destined to become more concerned with teaching than research will quickly find themselves bereft of teachers.

The chances are that neither the British government nor the committees such as UFC which it appoints to do its work are conscious of that danger. Certainly the government, believing as it does that academics are layabouts and persuaded by its disdainful convictions that everybody else would wish to be a layabout if he had the chance, behaves as if the supply of academics is literally endless. The logic is faultless, but the premises are wrong. Even academics will not endlessly put up with the self-abnegation required of British academics in the past decade. Push them a little harder and they will move into the City of London — or even politics. How will UFC plan for that. □

Space station the victim of US budget difficulties

- International collaboration in the balance
- Reduced capabilities for early missions

Washington

REPRESENTATIVES from NASA (National Aeronautics and Space Administration), ESA (European Space Agency) and Japan's Science and Technology Agency are meeting this week in Paris to discuss plans to scale back the space station Freedom in anticipation of cuts in NASA's budget. US proposals to "rephase" the space-station programme have angered its international partners, who say that if the United States breaks the terms of the intergovernmental memoranda signed last year it will jeopardize future international cooperation in space.

Under discussion in Paris will be plans completed last month by researchers at NASA's Langley Research Station. Ray Hook, director for space at Langley, says the group tried to find a way to cut development costs by 20 per cent and to produce a programme that would "eventually achieve the capacity that the current configuration has but at some later date". The plans are made necessary by budget restrictions. The House of Representatives has already cut $400 million from its 1990 request of about $2,000 million for the space station and the Senate may take similar action in the next few weeks.

Bill Oran, of the House of Representatives subcommittee on space science and applications, says that, further into the future, "the budgetary pressures are not going to go away" The international partners are up in arms over the proposed changes. Heinz Seipel, science counsellor at the West German Embassy in Washington said they would create "tremendous uncertainty" in the dates for attachment of the modules and in the dates when full power would be achieved. "The international partners have to make investments in billions . . . and rely on promises. That just one year after the agreements have been signed there are cutbacks does not increase the confidence of the partners in the stability of the system", he said.

Takehiko Kato, US liaison officer for the Japanese National Space Development Agency says the changes would cause "big problems" for Japan's module and that the number of experiments would have to be reduced. If the United States cannot honour the agreement signed last year, "nobody's going to work with the US any more because they're so unreliable", he said. Japan has complained formally to the United States and is awaiting a response at the meeting this week.

The new plans include drastic reductions in power, data-management capabilities and the number of personnel on board during the initial stages of the programme. But Hook says the programme could be restored to full capacity by 2000, two years behind schedule.

Other possible changes include: reducing communication and tracking capacity; minimizing or abandoning plans to allow the crew to work outside the space station; reducing navigation and control capability; using different life-support systems.

Instead of eight crew members there would only be four and power would be reduced from 75 kW to 38 kW. Of this only 18 kW would be available for users, instead of 45 kW. A spokesman for NASA said that if research projects are re-scheduled to make maximum use of the available power, then research will not have to be cut back. Hook said that although some experiments would be deferred, some of the instruments would not have been ready in time to meet the original schedule.

Inadequate power is one of the problems identified by a committee convened by the National Research Council at the request of NASA to study the engineering and design of the space station. In its report, published last month, the committee says the estimated power requirements were too low for the 'housekeeping' systems and the research projects.

Under the plan put forward by Langley, the date for first launch remains as scheduled, in the first quarter of 1995, but other launch dates are delayed by up to six months. Man-tended capability slips from the fourth quarter of 1995 to the first quarter of 1996 and permanent-manned capability slips from late 1996 to late 1997. The launches of the Japanese and European modules, due in late 1997 would also slip by up to six months.

Some consolation for the delay is that NASA will have more time to tackle some of the technical hurdles still to be overcome. The NRC committee says that the plan for advanced automation and robotics is "too small to address the magnitude of problems that the Space Station will likely encounter". It also warns NASA of the consequences of not paying more attention to the standardization of equipment. The design of the space station, it said, is becoming increasingly complex because of congressional directives, the shuttle's limitations and annual budget uncertainties, which are causing "schedule and programmatic turbulence".

HIPPARCOS

Original mission abandoned

Munich

THE European Space Agency (ESA) gave up hope last week of bringing the astronomy satellite Hipparcos into its intended orbit. Instead, project leaders were to sign an agreement on 4 September to try to salvage the mission by raising slightly the current elliptical orbit. They expect to begin this by 7 or 8 September. The new orbit would yield a sharply reduced amount of data.

The Hipparcos mission, named after the second century BC Greek astronomer who drew up the first star catalogue, was intended to measure the precise positions, parallaxes and proper motions of stars. After a perfect launch on 8 August, ESA was unable to fire the apogee motor in order to raise the $360-million satellite into a geostationary orbit 36,000 km from the Earth (see *Nature* 340, 491 and 581; 17 and 24 August 1989).

If the rescue mission succeeds, Hipparcos is expected to last just six months before its solar panels succumb to the bombardment of protons and electrons in the Van Allen belts, 5,000 km up. This decrease from the original 30-month mission would sharply reduce the accuracy of the data that could be collected.

The salvage operation will attempt to use the hydrazine thrusters on the satellite to boost its perigee (closest approach to Earth) from 208 km to 460 km This would reduce aerodynamic drag on the satellite and, researchers hope, give it a longer lifetime.

Raising the orbit does not guarantee that even the reduced mission can be completed. Beatrice Lacoste of ESA said last week that deployment of the solar arrays, baffles and the antennas are all controlled by motors that might fail.

The cause of the apogee motor failure is still unknown, despite five diagnostic tests carried out up to 25 August. The 500-kg motor is one of the few systems on board that does not have a back-up. A commission of inquiry was appointed last week to investigate the failure.

Another danger point will occur in January, when the Earth will pass between the satellite and the Sun, blocking the light for more than an hour. The satellite was not designed with such an occultation in mind, said Lacoste. ESA researchers are trying to find a way to prevent a power failure during the blackout.

The powerful ESA scientific programme committee will meet on 18 September to discuss whether to build a second satellite. The question is important, because a new satellite would cost £114 million ($182 million). ESA could ask the 13 member states for the money, or the committee could reapportion it out of the existing science programme budget.

Steven Dickman

New projects flood Japan

Tokyo

JAPAN's ministries and agencies last week bombarded the Ministry of Finance with new projects related to research on the global environment in their budget proposals for the next fiscal year Several of the requests are to establish new research centres, the biggest of which will be a new institute financed by the Ministry of International Trade and Industry (MITI) to develop "environment-friendly" technology

The budget will not be finalized until the end of this year but requests related to science and technology usually undergo only minor adjustments in the end-of-year negotiations.

MITI has asked for ¥8,540 million ($60 million) to set up the 'Industrial Technology Research Institute on the Global Environment', an enormous request for the first year of a new project. MITI hopes to plough about ¥2,000 million of this into development of substitutes for chlorofluorocarbons and into methods of converting carbon dioxide into useful products. Both chemical and biological carbon-dioxide fixation will be studied, according to Hiroshi Asahi, deputy director of MITI's Environmental Protection Division.

The new institute will also develop biodegradable plastics and use biological reactions to produce useful chemical materials, Asahi says. He expects the institute to be staffed by about 50 researchers from industry and MITI's national research laboratories in its first year And he says that MITI hopes industry will provide about one-third of the costs of joint development programmes which will run for three to five years

The Environment Agency, which survives on a budget about one-twentieth that of MITI, wants almost to treble its outlays for global environment research to ¥2,400 million ($17 million) Half of this sum will provide new funds to promote research on the global environment in universities and research institutes both in Japan and overseas. But the agency is not sure how it will channel funds to foreign researchers. The accounting is a "difficult problem", says Yasuo Takahashi, section chief of MITI's Environmental Research and Technology Division.

The agency has also requested ¥423 million to establish a new centre for global environment research at its National Institute for Environmental Studies in Tsukuba The centre will have a permanent staff of between 10 and 15, as well as guest researchers, and agency officials hope to lease a supercomputer. The centre will concentrate on monitoring environmental problems in the Asia–Pacific region, Takahashi says.

The Science and Technology Agency also wants to reorganize its National Research Center for Disaster Prevention in Tusukuba, to incorporate global environment research and has requested ¥194 million to do so. And the agency hopes almost to double its outlay for remote sensing of the Earth (¥4,190 million), including development of the advanced Earth Observation Satellite (ADEOS) which is scheduled for launch in the mid-1990s.

The Ministry of Foreign Affairs seems set to get the biggest percentage increases in budget with a request of ¥534,000 million, nearly 15 per cent up on last year Most of the request is for Overseas Development Aid (ODA), a large percentage of which is earmarked for protection of the global environment. At the Paris summit in July, former Prime Minister Sousuke Uno pledged to spend ¥300,000 million ($2,000 million) of ODA on the environment over the next three years. But Japanese ODA organizations are notoriously understaffed and lacking in environmental expertise.

The foreign ministry and the Ministry of Agriculture, Forestry and Fisheries have requested a combined total of about $10 million for the International Tropical Timber Organization in Yokohama. This will make Japan by far the largest contributor to the organization, which aims at promoting sustainable management of tropical rain forests. The agriculture ministry has also asked for several million dollars (¥394 million) to establish an information centre for monitoring changes in tropical rain forests using remote-sensing technology. But Japan, coming under mounting international criticism as the world's largest importer of tropical timber, has yet to take any measures to reduce its timber consumption

Even the Ministry of Construction and the Ministry of Transport have requested small budgets to study global environment problems. The construction ministry recently released a report estimating that sea level could rise by 0.5 to 1 5 metres by 2030 if the concentrations of carbon dioxide and other greenhouse gases continue to rise at their present rate The report calls on the government to add 4–5 metres to shore embankments as a protective measure. The transport ministry estimates a rise in sea level of 1 1 metres and says shore protection work will cost ¥3.8 million million ($26,000 million) The two ministries will carry out further studies of sea-level change and ways of reducing greenhouse gas emissions in housing and transport. **David Swinbanks**

US agencies unite on planet Earth

Washington

IN an attempt to integrate the key questions concerning global change and to develop a coordinated research programme, the US administration last week released a comprehensive plan setting research priorities for the study of planet Earth. The 196-page plan's key feature is that it is a cooperative effort from all of the seven US federal agencies involved in global change research.

It is the first time that they have all sat down together, shown each other their programmes and agreed to work together to "monitor, understand and ultimately predict global change".

The plan is the work of the Committee on Earth Sciences (CES) of the Federal Coordinating Council for Science, Engineering and Technology, an interagency body led by the White House Science Advisor. In essence, it is a manual for policy makers and those who decide how grants from research agencies should be given out.

But by repackaging a variety of research programmes from different agenciees, paid for from different budgets, into one whole, it will also provide a useful weapon in the fight for more funds to support global change research. President George Bush has proposed spending $191.5 million on global change research activities in 1990, an increase of 43 per cent over the current year. According to Dallas Peck, director of the US Geological Survey and chairman of the Committee on Earth Sciences, Congress so far appears willing to meet the president's request, and in some cases is providing "an embarrassment of riches." Substantial increases in expenditure are planned further into the future.

"Our Changing Planet: The FY 1990 Research Plan" groups scientific tasks into seven categories and ranks them in order of priority. The study of climate and hydrological systems comes top of the list, and within that category, the role of clouds and of ocean circulation are given the highest priority of all. The two topics are the biggest unknowns in models that attempt to predict whether substantial global warming will take place. Clouds both reflect heat back into space and trap heat in the atmosphere; how the distribution of clouds will be affected by global warming is thus crucial to predicting future temperature changes. The exchange of heat between oceans and atmosphere is dependent upon patterns of ocean circulation that again may be altered by changes in global temperature.

The goal of the research programme is to distinguish between and predict the effects of natural and human-influenced changes, not to set policy on how to slow global change. That will come only after much better predictions are available.

AUSTRALIAN RESEARCH FUNDING

Quarrel over share-out

Sydney

AUSTRALIAN medical researchers are once again complaining that they have been short-changed by the Australian Research Council (ARC) and, thanks to the way ARC is interpreting a government report, will be left without funds to support their research infrastructure for the next three years.

In its May science budget, the Australian government allocated A$107.5 million for higher education infrastructure. The allocation came in response to the Smith committee's report in March which recommended an increase in infrastructure support. The funds provide for items that are not covered by specific project funds, such as journal acquisition, animal-house maintenance and the purchase of general equipment. Medical researchers now find that they are ineligible for any part of these funds. Professor Don Aitkin, chairman of both ARC and the working party set up to decide how the funds should be distributed, says "for the ARC to provide research infrastructure to clinical medicine and dentistry would be to provide a certain amount of 'double-dipping'. The National Health and Medical Research Council (NH & MRC) received a separate allocation of $25 million to be spent over three years on "public health, training and equipment" in the May budget. Medical researchers had understood this money to be earmarked for new projects and scholarships; ARC believes it should be used to maintain research infrastructure.

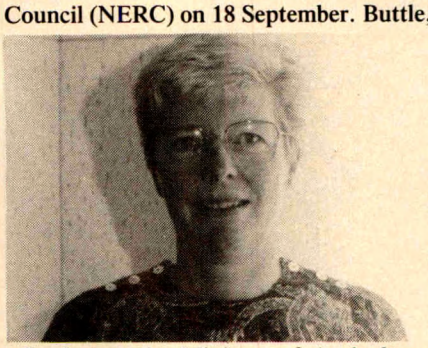
"If we did use the money for infrastructure, then we would have a static budget allocation over the next three years, which makes no sense", said Professor John Coghlan, chairperson of the Medical Research Committee of NH & MRC, and deputy vice-chancellor (research) at the University of Melbourne. "The working party misunderstood the [May] budget statement".

Medical researchers' problems are compounded by an earlier budget redistribution. Last year, the Minister for Education, John Dawkins, announced that A$125 million would be pulled out of the universities over three years and distributed competitively by ARC. The clawback, as it is termed, was to be taken out of operating grants. According to Professor Ian McLoskey, head of the faculty of medicine research committee at the University of New South Wales, "the money was taken out of operating grants and redistributed as project grants. When competing for project grants, it must be specified that infrastructure funding is already available. Where will that money come from?"

The Smith committee advised that medical research, which makes up 20 per cent of all research at universities, should receive 20 per cent of the clawback as competitive grants. ARC decided, however, to release only 10 per cent for medical research. While researchers were unhappy with this deal, worse was to come.

ARC interpreted the Smith committee directive to mean 10 per cent of the increase in funds, instead of 10 per cent of the total; this means that in 1990, when clawback funds go up from A$20 million to A$40 million, medical researchers will receive only A$2 million, rather than the A$4 million they expected.

According to Professor McLoskey, the A$2 million shortfall "accounts for 50 new projects a year out of a total of 750. This A$2 million is likely to hit the little battlers of medical research rather than block grants for institutions." There has long been tension between medical researchers and ARC. Medical researchers resent having their funding determined by a committee which grants them no representation. According to Professor David Penington, vice-chancellor of the University of Melbourne, the ARC's agenda is to reduce funding for high-profile areas such as medicine. "Professor Aitkin holds the belief that medicine has done well enough for long enough and, in the name of equity, they must give up some of their money to less high-prestige areas", he said.



Tania Ewing

UK RESEARCH COUNCILS

New secretary for NERC

London

DR EILEEN Buttle will become secretary of Britain's Natural Environment Research Council (NERC) on 18 September. Buttle,

who leaves the Ministry of Agriculture, Fisheries and Food (MAFF) where she is head of the Conservation Policy Division, was Establishment Officer at NERC from 1985 to 1988. She has a PhD for study in marine zooplankton, has worked at the Pig Industry Development Authority and the National Institute for Research in Dairying, MAFF and has joined the Civil Service Senior Professional Administrative Training Scheme. Ben Webb

MOUSE BREEDING

Jackson Lab should stand on its own feet

Washington

THE US National Institutes of Health (NIH) have indicated that they will not gladly accept money to reestablish the colonies of genetically inbred mice that were wiped out during the fire at Jackson Laboratory in Bar Harbor, Maine, in May (see *Nature* 339, 169; 1989).

Before its August recess, the Senate passed legislation introduced by Senator Edward Kennedy (Democrat-Massachusetts) authorizing a $25 million grant for the construction of a laboratory mouse-breeding facility, to be administered by NIH.

But NIH contend that as a private company, Jackson Laboratory should use its insurance money and other resources to recover on its own, without federal assistance. A policy statement prepared by NIH says that even if Congress allocates money for a facility to NIH, "the agency has a number of pressing needs for which the funds could be used". Breeding stock for the 1,700 strains of mice bred at Jackson Laboratory were saved from the fire; the company hopes to achieve half its production capacity before the fire within the next six months. Carol Ezzell

SATELLITES

First commercial launch in US

Washington

THE successful launch on 27 August of Marcopolo 1, a British communications satellite that will transmit television programming for British Satellite Broadcasting Ltd from a geostationary orbit above the Atlantic Ocean, marked the entry of McDonnell Douglas, the US aerospace corporation, into the field of commercial rocketry. Marcopolo 1, launched by a Delta 187 rocket from Cape Canaveral, went into space ahead of India's Insat 1-D, which was damaged on the launch-pad in June (see *Nature* 339, 649; 1989). The Indian satellite is under repair, and may now be ready for launch next spring.

McDonnell Douglas has been building rockets for the National Aeronautics and Space Administration (NASA) for decades. Its entry into commercial space activities was prompted by the Challenger shuttle explosion of 1986, which rendered NASA, until then responsible for all payload and manned launches, temporarily impotent. President Reagan then directed the US Air Force to put satellites into orbit using its fleet of expendable launch vehicles (ELVs), and also encouraged ELV manufacturers to offer their services commercially. McDonnell Douglas, along with Martin Marietta and General Dynamics, has dozens of commercial launches planned for the next few years. David Lindley

ANIMAL WELFARE

About-turn on regulations

Washington

In response to thousands of complaints about its original proposals to regulate the welfare of laboratory animals, the US Department of Agriculture has made a dramatic about-turn in its approach to the issue, conceding that research institutions should themselves decide how to meet the required standards.

But animal welfare groups are angry that almost four years after Congress passed the legislation requiring the new regulations, the result is 'performance-based' standards which will be difficult to enforce and, they say, may not improve the welfare of laboratory animals.

Parts one and two of the new regulations, developed by the Animal and Plant Health Inspectorate Service (APHIS), were published in their final form last week. Significant revisions from the original plans bring the regulations closely in line with the current Public Health Service guidelines. Dale Schwindeman of APHIS says that institutions already following those guidelines will have to make few changes to meet the new regulations.

The third and most controversial part of the regulations, which includes the standards for cage sizes, exercise for dogs and means for creating environments for primates in order to improve their 'psychological well-being', is being drastically revised in response to the 18,000 comments received since it was first published in March. Schwindeman says the final rule will not be ready before the end of the year.

Animal-welfare groups have won some small victories. The institutional committees which will monitor compliance with the regulations, with the power to suspend research immediately, must include one member of the public and to investigate complaints from the public. That the regulations acknowledge public opinion at all is "fantastic", says Bob Cotreau of the Animal Welfare Institute. He also applauds the fact that the regulations define pain according to human standards.

Despite strong opposition from researchers, APHIS insists that inspectors should have full access to research facilities with authority to take photographs and photocopy relevant documents.

It argues that the inspections would not disrupt research, and that documents would not be available to the public. Neither did researchers succeed in persuading APHIS that disclosing the location of facilities where animals are housed would create security problems.

APHIS originally estimated the costs of implementing the regulations to be about $900,000 million, but the ultimate cost will depend on the final form the standards take when they are published next year.

Christine McGourty

BIOLOGICAL ETHICS

Abortion issue destroys board

Washington

The US Congressional Bioethics Board seems certain to be dissolved next month after four years in which it has made no progress on any of its planned studies on controversial ethical issues in biomedical research and health care. The board has spent most of its time arguing over the selection of members of its advisory committee, with candidates' views on the abortion issue providing the litmus test for admission.

The board is a bipartisan group of 12 congressmen established to consider issues such as the withdrawal of nourishment from terminally ill patients, genetic engineering and fetal research.

The demise of the board is ensured by the action of its newest member, Senator Don Nickles. He has introduced an amendment to the bill that provides funds for the committee, blocking further expenditure until the board succeeds in selecting a chairman, vice-chairman and fills all vacancies on its advisory committee.

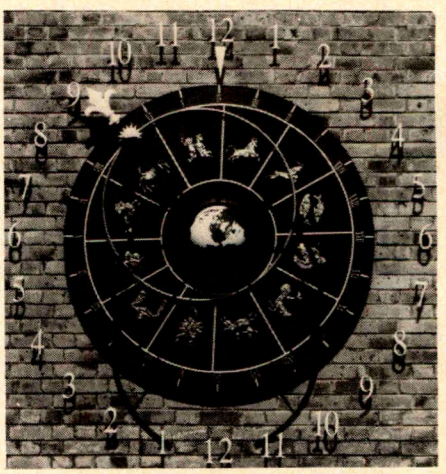
The Senate is likely to support the amendment when it votes on the bill in the next few weeks, making it impossible for the board to continue to function unless it can resolve its internal problems. That now seems virtually impossible.

Earlier this year, it seemed that the committee might finally be able to begin its first study, on genetic engineering, but the death of one member opened a new vacancy and all work was suspended.

One of the casualties of the board's inactivity is a decision on federal funding of fetal research, which rests on a report due from the advisory committee. At present only fetal research which is either therapeutic or within a strict 'minimal risk' standard can be carried out. That standard allows non-invasive procedures and blood tests but prohibits any new area of fetal research. Research that exceeds the minimal risk standard requires a waiver from the Department of Health and Human Services (DHHS). But in 1985 it was decided that waivers would not be issued until a report was received from the committee on their use.

Advocates of fetal research are divided over the existence of the Congressional Bioethics Board. "We wouldn't want it to be reauthorized if nothing is going to be done", said Sarah Carr, of the Association of American Medical Colleges (AAMC). "If you're opposed to fetal research then that's a good way to keep it from happening." Critics of the board say that the legislation that created the committee was designed in such a way that there would be a stalemate on everything.

The AAMC is urging the federal government to reconstitute a separate DHHS Ethics Advisory Board (EAB) whose charter expired in 1980. Advocates of fetal research were pleasantly surprised last year when the DHHS published a proposed charter for a new EAB (see *Nature* **334**, 185; 1988), but no further action was taken and a final charter has not been published. The AAMC recently wrote to the assistant secretary for health, James Mason, saying that "the absence of a board since 1980 has inhibited progress in all research involving human *in vitro* fertilization as well as research on the prenatal trans-mission of AIDS and on new diagnostic imaging techniques".



John Fletcher, professor of biomedical ethics and religious studies at the University of Virginia said there are signs that the reformation of the EAB "is being taken very seriously".

"Reproductive biology in the federal sector of science is being suppressed by the absence of the EAB . . . the US is way behind the United Kingdom in the study of the causes and treatment of infertility", he said.

The AAMC is also urging the Secretary for Health, Louis Sullivan, to lift a ban imposed last year on the use of fetal tissue in research. At that time the assistant secretary for health requested a report on the issue from the National Institutes of Health.

The report concluded that the use of aborted fetal tissue in research is acceptable provided strict safeguards are followed to prevent potential abuses (see *Nature* **339**, 411; 4 June 1989). No action has been taken in response to the report, which now lies with Mason.

Christine McGourty

This 8-foot-diameter astronomical clock was installed this summer at Leicester University. The astrolabe projection shows 'clock' time as GMT (the white fleur-de-lis), as well as sidereal and solar time, relative positions of Earth, Sun, Moon and stars, phases of the Moon and rising and setting over the local horizon. The clock was designed and built by Alan Mills and Ralph Jefferson.

GENETIC ENGINEERING

Dispute over monitoring

London

A DISPUTE broke out in the United Kingdom last week over responsibility for monitoring the release of genetically engineered organisms into the environment. The British government proposed recently that a new body should be responsible for environmental safety. But the Health and Safety Executive Executive (HSE), which has the responsibility now, and the Confederation of British Industry (CBI), criticized the government's plan.

The HSE's Advisory Committee on Genetic Manipulation (ACGM) bases its decisions on releases on legislation in the Health and Safety at Work Act, but its remit does not stretch to ensuring environmental safety. The Department of the Environment, in a green paper (consultative document) outlining legislation for this autumn's 'Green Bill', revealed plans to plug this gap with a new body. And this week the HSE agreed that "the absence of legal powers in the area of environmental safety must be addressed". But it warns against splitting the regulatory system between environment and the workplace and recommends the formation of a new committee under the auspices of the ACGM to advise the HSE and ministers on release proposals.

Brian Richards, chairman of the CBI's Biotechnology Working Party, also said a new body would be a mistake. "The ACGM has been doing a good job for years, and should be allowed to continue its work, strengthened to cover environmental issues", he said. "There is too much at stake to risk the introduction of sub-standard regulations." The Royal Commission on Environmental Pollution (RCEP) also recommended that the ACGM should be constituted in its own right to advise the Secretary of State for the Environment and the HSE on each proposed release. In a report that took three years to complete, the RCEP praised the committee and suggested it should also produce a code of practice, advise on the need for research and the possibility of categorizing new releases, and produce an annual report. The HSE also called for further discussion of the definition of genetic manipulation, the balance between protection of commercial confidentiality and public information and controls on products consisting of genetically manipulated organisms.

The Department of the Environment said the alternative proposals would be considered before the bill goes before parliament. The criticisms of the government proposals coincide with the announcement by the Department of Trade and Industry of a £1.3 million, three-year research programme into the "fate" of genetically manipulated organisms in the environment. The programme, called Prosamo (Planned Release of Selected and Modified Organisms), will investigate "new methods for detecting the spread and survival of very low numbers of modified organisms so that the results of releasing new products into complex natural environments can be assessed more accurately". **Ben Webb**

HUMAN FRONTIERS PROGRAM

Call for grant applications

Tokyo

JAPAN last week launched its long-awaited Human Frontier Science Program with a call for applications for grants, fellowships and subsidies for international workshops (see page 17 of 'Classified' in *Nature* of 31 August).

Twenty three-year grants worth about $500,000 a year will be awarded to international teams of scientists led by principal researchers from one of the seven 'summit' nations or non-summit European Community nations for research on the brain and biological functions at the molecular level. In addition, the programme will support about 150 long- and short-term fellowships and 10 workshops for research in these fields.

Conditions for the grant applications are similar to those for a 'pilot' programme launched last year, except that the research teams do not need to include Japanese. The pilot programme has come under some criticism from Western scientists whose applications failed because they received no explanation for failure (*Nature* 340, 494; 1989).

The guidebook for this year's grant applications retains a clause stating that "the review process will be confidential; no explanation , therefore, will be offered and no correspondence can be entered into on decisions taken". But Toichi Sakata, director of Frontiers at the Science and Technology Agency, says that once the Frontiers foundation is established in Strasbourg next month, the Frontiers science council and/or grant review committees can alter this rule if they think appropriate.

Last week, the agency and the Ministry of International Trade and Industry (MITI) applied for a total of ¥3,307 million ($23 million) for Frontiers in 1990. And with the increased budget and some support from other nations, Sakata hopes the number of grants will increase to "about 26 or 27" in 1990. David Swinbanks

RISKS TO ORIGINALITY

INSERM's man speaks out

Paris

IN a book due to be published shortly, the director-general of the French national institute of health and medical research (INSERM), Philippe Lazar, suggests that major journals inadvertently run the risk of discouraging originality in research. In a chapter entitled 'Avatars of originality', Lazar criticizes *Nature* over its reactions to the controversial paper by Jacques Benveniste on the molecular 'memory of water' (see *Nature* **340**, 178; 1989).

In his book, which gives the reader an 'inside view' of the preoccupations of the director of a national medical research organization, Lazar defends INSERM's practice of four-yearly laboratory reviews by an elected committee of experts. The system, he says, should maximize the emergence of "truly innovative work" because, for laboratories wholly funded by INSERM, the reviews are retrospective. But, says Lazar, research which is "off the beaten track" stands little chance of being published quickly, both because it is usually unproductive at first and because major journals may be reluctant to publish it. And publication is often a criterion of merit when assessing grant proposals.

By publishing Benveniste's paper on condition that the experiments be repeated in the presence of a panel sent by *Nature*, Lazar says that the journal cast itself in the role of scientific "establishment". He wonders whether *Nature*'s editors "had a real moment of difficulty at the idea of challenging, in their own right . . ." an example of "truly original research".

Nature, he adds, should have left it to the scientific community "to play its fundamental role of filter at its own pace". Any other procedure, he says, is "dangerous" and evokes "the spectre of 'official' science".

These are substantially the criticisms made by Lazar at a press conference last month at which it was announced that Benveniste's tenure had been renewed until the end of the year.

Lazar also attacks the press for what he considers an excessive zeal during the height of the affair.

To counterbalance the weight accorded by grant review committees to publication in major journals — and the consequent influence of conservative peer reviewers on the kinds of research supported — Lazar wants to offer a series of small grants for 'high risk' innovative research. He says he is not convinced the idea will work, but adds that he would "regret having to renounce the idea for want of support". **Peter Coles**

Les Explorateurs de la Santé is published by Editions Odile Jacob, Paris, later this year.

SOVIET NUCLEAR TESTS

Campaign to close Semipalatinsk

Moscow

A MOVEMENT whose goal is a moratorium on nuclear testing by the United States and the Soviet Union is making some headway. Last month, the organization, called the Nevada-Semipalatinsk Anti-Nuclear Public Movement, called on presidents Mikhail Gorbachev and George Bush to put an end to underground weapons tests.

The president of the movement, the prominent Soviet Kazakh poet Olzhas Suleiminov, who is also now a People's Deputy of the USSR, says that the "immediate goal is to close the testing-ground in Semipalatinsk (in Kazakhstan). But Suleiminov added that the goal will be attainable only if there is "simultaneous closure of the Nevada testing ground".

The movement was founded at the end of February this year, with a rally at Alma Ata, the capital of Soviet Kazakhstan. Its general aim is to put an end to nuclear testing anywhere in the world. The organization is hoping to pool its efforts with those of similar groups in the United States, for which purpose a member of the movement's coordinating council has visited the United States, meeting among others Dr Bernard Lown, co-chairman of International Physicians for the Prevention of Nuclear War.

The Neveda-Semipalatinsk movement accuses the Soviet authorities of concealing the consequences of the testing programme in East Kazakhstan. The group's formal statement says that both ill-health and mortality increased in the neighbourhood of the testing-grounds over the forty years they have been in use, adding that "this was concealed from us". It complains that problems occasioned for public health and the environment during the testing programme were neglected.

The report of an expert commission formed on the instructions of the Soviet government, which concludes that the radiation in Semipalatinsk and surrounding districts is normal, has been met — mildly speaking — with open mistrust by the local people. The letters with which state and public offices have since been deluged have been full of tales of suffering and sorrow.

E.I.Proskurina, born in Semipalatinsk in 1936, says that "everything that once made me a woman was cut out, and I do not know who I am now". Zh. Zhuniszhanov describes having seen "with our own eyes enormous blinding glows which turned into mushroom clouds ... the gullibility was so great that we did not feel the danger and did not attach any importance to these sights".

Among the letters is one from 20 war and labour veterans who say they were, like others in the Abai district, subjected to radiation from the testing of a hydrogen bomb in 1953. In the rural area of Sarzhai, 240 people are under medical supervision. Cancer, anaemia, allergy and neurosis are common, child mortality is high and suicides among young people have become more frequent.

Although there have been only underground tests since 1963, they have caused repeated emissions of radioactive gases, most recently on 12 February, and background radiation has been increasing. The effects of seismic stress are another source of trouble. A public opinion poll carried out in May and June showed that 99 per cent of the inhabitants of three districts adjacent to Semipalatinsk felt unwell the day after an explosion, and that 99.5 per cent are convinced that the testing-ground endangers their health.

Saim Balmukhanov, a member of the Kazakhstan Academy of Sciences, says that the number of people suffering from blood diseases has doubled since 1970 and that infant mortality has risen sharply, to 43.5 deaths per 1,000 newborns. Now, in a street in central Semipalatinsk, there is a drugstore in whose window can be seen a dosimeter showing the radiation level in the city, put there at the urging of the movement that seeks a moratorium on nuclear testing.

Vladimir Lysenkov/Novosti

RADIATION SAFETY

Byelorussian criticism

London

THE Byelorussian Academy of Sciences is highly critical of the standards of radiation safety that were proposed by Moscow experts in the aftermath of the Chernobyl disaster, the president of the academy, Dr Uladzimir Platonau, told a recent session of the Byelorussian Supreme Soviet (parliament).

The Moscow experts from the Ministry of Health Protection and the All-Union Academy of Medical Sciences set a maximum lifetime radiation dose of 35 rems. People living in regions of greater risk are to be evacuated. But the caesium-137 pollution from Chernobyl is proving more extensive and far more difficult to remove than was originally estimated, and more than 103,000 inhabitants of the Byelorussian republic now face evacuation. Nevertheless, say the Byelorussian scientists, this limit is not only scientifically doubtful but is also "amoral". How, Platonau asked his fellow parliamentarians, can one have the same, artificial limit for adults, children, pregnant women and invalids? The real criterion, according to the academy, Platonau said, should be whether or not normal life can be sustained in a given area.

Approximately one-fifth of all agricultural land in Byelorussia is at present unfit for agriculture, and the residents of these erstwhile collective and state farms have to be supplied with milk, meat and vegetable products from outside. The cost of this operation is so high that, according to one Byelorussian estimate, if the whole of the contaminated area were evacuated, the outlay, including building new homes, schools and amenities, would pay for itself in eight years.

Platonau's proposal is less drastic and more democratic. He suggests that a maximum lifetime dose of 7 rem (the international standard for nuclear power station construction) should be adopted as an evacuation threshold. People living in areas of higher risk should be given the fullest possible information about the degree of pollution and the risk factors, and should then be given the option of evacuation.

Ever since the Chernobyl accident, in April 1986, Platonau and his academy colleagues have been concerned about the consequences for Byelorussia, but have received short shrift from Moscow. Two years ago, he told the Supreme Soviet, they had put a number of questions about radiation safety standards to the Moscow experts, only to be told that "you are not medical experts, and there is no need to discuss these doubts further". It is true, Platonau said, that the Byelorussian Academy has no medical institute, and that its Institute of Radiobiology was founded only in 1987. Nevertheless, during the past year, Platonau said, he has been collecting all relevant data on radiation safety from his biologist and chemist colleagues. This material, he said, "has made it possible to draw the attention of the broad scientific community and the leaders of our country to the fact that the situation is far more complicated than certain comrades imagined". The Byelorussian concern about post-Chernobyl health risks is shared by the Ukrainian Academy of Sciences, which also queries the scientific validity of the 35-rem limit, and whose president, Dr Borys Paton, has proposed a moratorium on nuclear power construction until a safer generation of reactors is available, and the health risks better understood. Somewhat unexpectedly, the All-Union Party daily *Pravda* has shown itself to be sympathetic to the Byelorussian case, even emphasizing, for example, the shortage of diagnostic equipment to examine children with thyroid problems associated with iodine-131 fallout from Chernobyl.

Vera Rich

ALASKAN OIL SPILL

Rescued sea otters fly the coup

San Francisco

INITIAL radio transmitter data from the 193 captured sea otters which were released into Prince William Sound late last month have held several surprises for marine biologists tracking the mammals. The otters had earlier been rescued from the giant Alaskan oil spill.

Despite rough weather that disrupted signals, researchers have stayed in touch with the 45 otters carrying surgically implanted radio-transmitters. All were released north of Cordova, in the eastern part of Prince William Sound and away from the devastating effects of the March spill of some 10 million gallons of crude oil. The slick drifted west into the Kenai Peninsula area, where most of the captured otters were rescued.

So far, however, it seems that none of the otters has returned home. "Our best information is that the otters are all still in the sound", says Tony DeGange, a wildlife biologist with the US Fish and Wildlife Service.

They were thought likely to move back to the Kenai, where they were caught. But most have dispersed from the release point, and a few have already travelled several hundred kilometres.

Wandering is expected, especially among females, which have large seasonal movements compared to the more territorial males.

Researchers next plan to install radio-tags on other otters that remained free

throughout the crisis. Some will come from the oil-spill zone, the remainder will be a control group from untainted eastern waters. The idea is to "validate the whole rehabilitation process", says DeGange, and to see if the otters that were treated and released "become full-functioning members of the sea otter community again". The free-ranging otters from the spill area will be compared with the control group to see if reseachers can detect any effects — in survival and reproductive rates — of living in the oil zone.

Robert Buderi

UK ATOMIC ENERGY

Slimming down for sell-off

London

THE United Kingdom Atomic Energy Authority (AEA) is to undergo a rigorous rationalization programme aimed at attracting finance from the private sector after a series of cuts in government funding. The authority will split its business activities into nine discrete areas, each covering a sector of research which is considered commercially viable. John Collier, chairman of AEA, revealed last week that nine chief executives would head the subsidiaries independently under the authority's new commercial banner, AEA Technology.

The nine business areas are the fast reactor, fusion technology, nuclear fuel cycle technology, environmental protection services, thermal reactors, contract research, oil and gas, risk management technology and decommisioning and radioactive waste management.

The AEA had incurred inevitable restructuring costs and had to reduce manpower to fit estimated future turnover and compensate for the reduced government contribution to research into the fast reactor, according to Collier. These costs, with a £27 million provision for the future, left the authority with a current loss of £41 million for 1988–89.

Collier criticized government cuts in support for the fast reactor and energy research programmes. "To be serious about nuclear power requires us also to be serious about the fast reactor", he said. The government has also warned that it plans to cut support for the Dounreay fast reactor and fusion work at Culham.

But Collier introduced a note of optimism when he revealed that the authority had signed a series of agreements in Bonn to ensure British involvement in the future of European research into fast reactors. He said the deal provided a "sound basis" for the AEA to move to the "demonstration phase" of fast reactor development with partners in France and West Germany.

"The European collaboration is the best and perhaps only way for the UK to ensure fast reactors are available when we need them early next century", he said.

EARTH SCIENCES

Germans to drill to 10 km

Munich

THE West German government announced last week that it will continue to pour money down a hole in northern Bavaria. The money, DM500 million in all ($256 million), is to be spent on what was meant to be the deepest hole in the world. Now the hole will go only 10 km down, but it will still give geologists a glimpse of an unexplored part of the Earth's crust.

The decision to go ahead with the project, officially known as the "Continental Deep-Drilling" project (KTB in German), was based in large part on the success of a 4,001-metre-deep pilot hole drilled near the Bavarian town of Windischeschenbach. Researchers will begin drilling the deeper hole in August 1990. They hope to complete it in 1994.

The West German geology community strongly supports KTB, which, along with the Soviet deep hole on the Kola Peninsula, is one of the most ambitious deep-drilling projects in the world. The West German Research Ministry (BMFT) has also been generous in its support for KTB. The latest budget includes an increase of DM50 million above the original figures. But a BMFT spokesman stressed that the ministry was backing KTB entirely for scientific reasons, and not, as some have speculated, because of the good publicity the project has been generating.

Plans to drill to 14 km had to be abandoned when the pilot hole encountered the unexpectedly high temperature of 118°C at 3.5 km. The temperature will probably climb to the functional limit of the equipment — 300°C — by the time the hole reaches 10 km. If it is less hot, the researchers will decide in 1993 if they want to try to drill down to 12 km. Ironically, the drilling site was chosen because the crust was expected to be cooler than at other sites in West Germany.

And there have been other surprises. The cores brought up from 3 km were under extreme stresses that researchers had expected to find only at 7 km or deeper. At 3.4 km, the drill-bit hit fissures filled with salty brine that may be a remnant of primordial oceans.

Below 3.2 km, large amounts of helium and methane were found. The methane may derive from the crust itself, rather than organic matter on the surface, lending support to those, such as astronomer Thomas Gold, who claim that natural gas can be found in the crust. Gold has led a deep-drilling project in Sweden intended to find useful amounts of methane gas in crystalline rock, where it has never been found before.

The KTB team has also made advances in drilling technology. For instance, they have developed a special 'drilling mud' a colloidal silicate pumped into the hole to lubricate the rotating diamond drill-bit which oozes up the hole, shoring up the walls.

Steven Dickman

More on animal experiments

SIR—Clive Hollands is to be commended for raising important issues regarding the responsibilities of scientific journals to uphold ethical standards regarding animal experimentation, (*Nature* **339,** 248; 1989). Hollands specifically objected to *Nature*'s publication of experiments, conducted in France, involving major surgery with anaesthesia on two pregnant macaque monkeys to remove bilaterally the eyes of two fetuses (*Nature* **337,** 265–267; 1989). The fetuses were returned to the uterus and the pregnancies later terminated by caesarean section. The young monkeys were allowed to survive for some weeks and were then killed for tests to assess the influence of retinal input on cortical development. "Such gross interference with a highly intelligent species requires overwhelming justification — if it can be justified", says Hollands. He considered these experiments would not be legal in the United Kingdom.

A subsequent leading article responded by stating that *Nature*'s "rule of thumb" has been "that the results of animal experiments that would not easily win general regulatory consent had better be of exceptional interest if they are to be published" (*Nature* **339,** 324; 1989). On two grounds, this is an inadequate response.

First, *Nature* gives no evidence that the criterion of "exceptional interest" is explicitly taken into account. Both the significance of the results and the trauma to the animal have to be identified in order to weigh the justification for conducting the experiments. The exceptional interest of retinal input on cortical development should not be assumed to be apparent to all readers.

Second, *Nature*'s "rule of thumb" does not incorporate the concept that some procedures are beyond the pale irrespective of possible scientific merit. As Patrick Bateson, professor of ethology at the University of Cambridge, speaking for the animal ethical review committee of the journal *Animal Behaviour* has said, "If suffering was likely to be intense, we would not regard work as acceptable and would recommend rejection (for publication) even if the work was of high standard", (personal communication, 28 October 1985). He goes on to say: "Intermediate levels of suffering would be justified by high quality work. Low quality work would not justify any level of suffering and, in any event, would not be published in the journal anyway."

So how should journals handle manuscripts submitted for publication that appear to raise serious ethical issues? Should journals merely act as "passive entities", as John Maddox describes, leaving it up to the scientific community to make subsequent judgement (*Nature* **339,** 657; 1989)? Or should journals assume an active role in helping to uphold high ethical standards? I believe the latter is the responsible course.

Two pioneering journals have established commendable procedures for handling questionable animal experiments and have published meaningful and detailed policies on animal experimentation which appear in instructions to authors (*Pain* **12,** 199; 1982 and *Animal Behaviour* **34,** 315–318; 1986). The journals' manuscript reviewers are specifically charged with ensuring their compliance, and manuscripts identified as involving questionable animal experiments are referred to special committees for determination.

I do not have personal experience of serving on such a committee, but it seems to me that they could decide on one of several courses depending on the seriousness of the concern:

(1) reject the manuscript on humane grounds,

(2) require modification of the manuscript by the investigator for instance, to include any or all of the following: justification of the importance of the work; a description of the severity and duration of animal pain; a description of the procedures taken to alleviate the animals' suffering or

(3) publish the article with an editor's note drawing attention to the concerns (see, for instance, the editorial note that accompanied an article in *Animal Behaviour* **32,** 293–294; 1984).

Publication of an article suggests scientific approval and tends to legitimize the work. It should be reserved for meritorious work that complies with the highest ethical standards of the day.

A creative force?

SIR—I am a scientist by training. I believe that an understanding of the Universe can be obtained only through careful observation. Models that allow us to comprehend observable phenomena can be constructed, but only when a model has been tested experimentally can it be held as truth. Nevertheless, I find myself flirting with explanations to problems that cannot be tested, knowing full well that until they can, I cannot allow myself to 'believe' in them as possible representations of truth.

My 'flirtation with the untestable' falls into two categories: phenomena that are occurring outside our time frame (such as the developmental diversification of life forms on Earth), and phenomena that occur within our time frame but seem to involve processes for which only the results are physically observable (such as 'human intelligence' and biological 'drive', and the 'experience' of them by the individual). I have no illusion that this flirtation with the untestable is anything other than religion, because the explanations my mind comes up with invariably involve an unknown, creative force. For a scientist, this is heresy. I should not be seeking to comprehend the Universe with untestable theories that postulate the existence of an unobservable 'force'. Untestable theories in science (such as the evolution of life through random diversification followed by natural selection), are permissible, but not if they involve forces from an unknowable source.

Ultimately, when I hold such beliefs, I must give up my scientist's persona and put on a religious one. For although I continue to use scientific truth to formulate a higher-resolution picture of the knowable Universe, I still find myself groping at 5,000-year-old untestable models. Instead of Adam and Eve, my creation myth begins in a 'primordial soup' with 'self-replicating molecules'. My struggle with the mystery of human consciousness uses terms such as 'mind-brain problem' and 'immanence illusion' rather than 'soul' or 'God'. I think in terms of 'creative and degradative' forces rather then forces of 'good and evil'. But when faced with the essential question — is there a creative force manifesting itself in the observable Universe? — I can answer yes, not with irreverence to any law of physics, but rather out of a sense of awe, in the face of utter bemusement.

Nuclear power

SIR—Although I was a signatory of the Greenpeace declaration on global warming, I nevertheless agree with Max Beran's strictures (*Nature* **340**, 336; 1989). The text reached me about a week before it was due to be published and I immediately rang Greenpeace to say that I should be glad to sign but asked them to change "irrelevant" to something like "hardly relevant" or "little relevant". I was told that it was too late to make changes and I then signed. I should have declined, although I agreed with the declaration as a whole. Scientists should avoid using sweeping or emotional terms they cannot justify, even if they do so to correct a false and irresponsible ministerial statement.

Thanks for your help!

We asked you, the user of oligonucleotide synthesizers, the producer of oligonucleotides, how we could improve oligonucleotide synthesis for you. The result was Gene Assembler® Plus, our new oligonucleotide synthesizer.

As Easy as A, C, G, T . . .

- **Truly easy software**, making handling, synthesis and maintainace really simple.
- **Preprogrammed optimised synthesis methods**, including custom synthesis and a program for 5'-aminoalkylation.
- **Unique monitoring system**, reporting the success of synthesis with automatic feedback control to interrupt the synthesis if something should go wrong.
- **Automatic documentation**, of sequences and results.
- **PAC amidites for better results.** PAC amidites give a purer product due to less depurination.
- **Faster results**, deprotection with PAC amidites and support takes only 60 minutes.

The concept of Gene Assembler Plus is to make oligonucleotide synthesis easier, to improve performance and results. Thus making it perfect for all oligonucleotide synthesis including PCR primers.

The positive reaction Gene Assembler Plus has received testifies to the contribution you've made.

Why not contact us today and find out more about what Gene Assembler Plus can do for you!

We help you manage biomolecules.

Olympus autofocus photomicrography takes the error out of focusing

What the naked eye perceives as sharp and clear often translates into a blurred image on film or paper.

Now Olympus brings you the Vanox-S—the world's first autofocus photomicroscope system—designed to eliminate focusing error in low magnification photomicrography (objectives from 1X to 10X), and ensure needle-sharp imagery throughout the entire magnification range. All you have to do is push the AF button.

And the Vanox-S also enables the use of two 35mm cameras and a large-format camera, incorporated into the body, together with automatic exposure and four photo eyepieces. Light intensity is adjusted with neutral density filters, maintaining color temperature consistency.

The new Vanox-S research photomicroscope system lets you reproduce the actual image you see accurately and with high quality. More easily and consistently than ever before.

The peripatetic fossils: part 2

Vishwa Jit Gupta

On 20 April 1989 *Nature* published an article by Dr John Talent accusing "one Indian scientist" of corrupting the palaeontological literature on the Himalayas. Below, that scientist — Professor V. J. Gupta — replies. On pp.13–16 appear four other articles, each of them prompted by the appearance in print of Talent's allegations.

JOHN Talent[1] has claimed that fossil work in the Himalayas is completely unreliable because I salted rocks with specimens bought in Europe and Africa. In doing so he implicitly attacks anyone who has worked with me and dismisses out of hand the vast amount of Himalayan research by many other authorities. In none of his publications or statements on the subject has Talent[1–3] referred to the meeting in Calgary in 1987, when I made an open offer to the audience to visit me at Chandigarh and discuss my research — indeed, it seems he has not recently examined any of the relevant fossil collections.

Talent's attack rests on four assertions, derived mainly from the literature and anecdote, not scientific enquiry: (i) the fossils reported by me are from inaccessible areas; (ii) those fossils are anomalous and incompatible with known models; (iii) lithologies described by me are at variance with those described by others; and (iv) I have duped my co-authors the world over

Tagging the name of one person to the fossil collections Talent refers to is gravely misleading. It is seldom possible to do fieldwork in the Himalayas by oneself. The collections were made by various teams of geoscientists.

For example, collections from Ladakh were made by members of the Manali–Leh Expedition (1969)[4] which included eight geologists (V.J. Gupta, G. Mahajan, S. Kumar, S. Chadha, P.C. Bisaria, N.S. Virdi, N Kochhar and S.R. Kashyap). The collections from the upper Spiti valley were made by S.P. Jain and V.J. Gupta (Lahul–Spiti Expedition, 1965)[5] whereas collections from Kaurig in Kinnaur and parts of lower Spiti were made by a field party (Lower Spiti Expedition, 1966)[6] which included three palaeontologists (S.B. Bhatia, V.J. Gupta and S.P. Jain) and a structural geologist (R.C. Kanwar). Collections from the north-eastern Kumaun were made by the members of the Kalapani–Kuti Expedition (1971)[7,8] to the north-eastern Kumaun organized by the Wadia Institute of Himalayan Geology, including K.S. Valdiya, K.B. Powar, D.M. Banerjee, V.J. Gupta, S. Venkatachalam and C.M. Khanna Field work in Nepal was done jointly with V.S. Chhetri, Senior Geologist of the Nepal Geological Survey, Kathmandu[9].

In addition, collections were made from time to time by myself, my post-graduate students and research scholars working in different parts of the Himalayas. At times collections were also made by geologists from other organizations and submitted to us for joint work. Some of the collections were even received from foreign geoscientists. Several papers were published in different scientific journals on the basis of preliminary field observations under joint authorship with the members participating in different expeditions or field works[4–9].

Some remote parts of the Himalayas are now served by roads, but conditions for geological field work were very bad when we started research about 25 years ago. Even with the help of porters and bearers only limited collections of rock and fossils could be brought back. This does not mean that we should doubt the veracity of the resulting data. Further, the government did not allow us to use detailed topographic or army maps, leading to difficulties in giving precise locations.

The so-called "faunal anomalies and incongruities" referred to by Talent[1,2] call for explanations, not accusations. Geology (especially Himalayan geology) is a developing science where anomalies should provide food for thought. Talent's conclusion of fraud[3] is in part a consequence of over-hasty analysis. To help justify his cause he dismisses the value of various scientific journals, presumably because they are Indian. This no doubt, in Talent's opinion, is the failing of *Contributions to Himalayan Geology* which has attracted international contributors and subscriptions. It is a publication India can be proud of — but that to Talent is a contradiction in terms.

This close similarity of faunas recorded from different stratigraphical horizons of the Himalayas with those of other regions, their mode of preservation and the lithology of the rocks (including matrix accompanying the fossil specimens) from which they were collected have been commented upon in the original publications. The apparently controversial find of graptolites was first reported by myself and M. R. Sahni in 1964[10,11] and has been corroborated by subsequent workers[12–14]. Talent ignores these papers. Similarly, the discovery of fossils from the Muth Quartzite has been confirmed by several workers[15–17]. The graptolites and other fossils from the Muth Quartzite were examined by Sir C. J. Stubblefield, at that time Director of the Geological Survey of Great Britain. The late Professor M. R. Sahni, under whose guidance the work was carried out, himself visited the fossil localities in Kashmir in October 1964.

The Muth Quartzite is a time-transgressive sequence and there is nothing contradictory in its lower and upper boundaries straddling the upper Lower and Upper Devonian. As such, these findings substantiate my impression of its varying ages in different sections. The sequence lying below the Muth Quartzite exposed in different parts of Spiti and Kinnaur (Takche, Gechang, Muth-Shian, Leo and Manchap) has been investigated in detail and Silurian age has been assigned to the reef buildups at these localities[18]. Among the fossils recorded from the reef buildups are corals, stromatoporids, solenoporids and so on. The Silurian reefoidal sequence at most of these localities is overlain by arenaceous rocks enclosing a few tabulate corals and *Psilophyton*[18].

The remarkable similarity of the Devonian conodont fauna from the Himalayas to that from other areas was pointed out independently as far back as 1967[19]. The close identity between the Himalayan and North Evans conodont fauna was also discussed, in 1975 (ref. 20). The Devonian conodont fauna is fairly widespread in the Himalayas and is being worked out in detail on the basis of fresh collections from measured sections. We plan to undertake geochemical analysis of the conodonts using various techniques (ICP, AAS, EDX, radio mass spectrometry for stable isotopes) and our Institute is in the process of acquiring and commissioning the sophisticated equipment involved. All these data will help in ascertaining the elemental/isotopic (ratio) composition of the conodonts. This will enable us to compare the composition of our Himalayan samples with that of identical forms from different parts of the world, including the North Evans conodont assemblage. The occurrence of Devonian conodonts corresponding to the *tringularis* zone has also been reported by independent authorities from the Dolpo region, which lies "north of Dhaulagiri" in Nepal[21], as well as from the Phulchauki section[9]. The Godavari–Phulchauki section is structurally very complicated, not at all like that described by Talent[1,2]. There is a complete succession of rocks ranging in age from Cambrian to Devonian in this section, and several lithological units are

structurally repeated

Talent[1,2] questions the occurrence of "dolomitic sandy limestone horizons" within the Muth sequence. What can one say? Such rocks *are* widely present, and no one could doubt this in the field. Dr A. D. Ahluwalia is planning to write separately on the Muth–Lipak transition of this section, as the collection referred to by Talent was made by him[22] and not by me. The occurrence of sporadic beds of ochreous weathering dolomitic limestone has been recorded from the Muth Quartzite exposed in the Chumik–Marpo area of southern Zanskar in Ladakh[23,24], Kumaon[25] and Western Nepal[26].

Lithological variations are likely to occur in sections where one formation grades into another. The boundary must be arbitrary, as is the case with the Muth Quartzite succession and the overlying Lipak Formation as well as its equivalents in different parts of the Himalayas. To date, no stratigraphical or structural break has been reported between the fossiliferous Early Carboniferous sequences and the underlying Muth Quartzite succession.

The close similarity of many elements in the Devonian fauna of the Himalayas and other Asiatic regions to the corresponding North American faunal elements has been noted by a number of leading workers since 1913 (refs 27–31). The Zebingyi Beds of Burma have yielded many Devonian fossils which closely resemble the fauna from the Manlius Limestone of New York and lower Monoran of Michigan[29,30]. Many species described from the Wetwin Shales are identical to the Naples fauna of western New York[31].

The similarity of the Devonian ammonoids from the Khimokula section to those of North Africa (Morocco, Algeria), Western Europe (Germany, Poland, Spain) and Asia (USSR, Mugodjar region of the Ural Mountains, China) was originally pointed out by the authors concerned. We were aware of the mode of preservation of our faunal assemblage. As pointed out in our paper[32], Dr J. Thein (Bonn) carried out the determination, by X-ray diffraction, of the mineralogical composition of the Himalayan ammonoids. The morphological differences observed, in comparison to specimens from other regions (including Morocco), were discussed. For example, the Himalayan samples of *Discoclymenia cucullata* (v.Buch) differ from those described from North Africa[33] in their whorl section, which is slightly broader across the flanks. In this respect the Himalayan ammonoids show close resemblance to specimens described from the Ural Mountains[34], from which they differ somewhat in having narrower venter and the less pointed adventitious lobe. Conodonts have also been recorded from the upper units of the Muth succession in this area and more work is needed to look into the possibility that reworking or condensation and intense folding has taken place. Poorly preserved cephalopods have been reported by other workers from the loose blocks of Muth Quartzite in the type locality (the Muth in Spiti)[27]. Fossils with a haematite mode of preservation are not uncommon in the Himalayas. Thick beds of haematite associated with the Phulchauki Series, exposed south-east of Kathmandu, contain casts and moulds of brachiopods, cephalopods, trilobites and crinoids[9]. It must be emphasized that well-documented Silurian and Devonian successions do exist in the Himalayas, which is proved beyond doubt by field and laboratory data collected from different sections

Lewin[3] suggests that I may have received Devonian fish specimens, described from Ladakh, as a gift from Dr Zhang Miman of the Institute of Palaeontology in Beijing. I have never met Dr Zhang Miman, nor have I ever visited her institute. The possibility of obtaining the fish as a gift does not arise.

I regret that Professor W. C. Sweet was mistakenly acknowledged in my paper on the Tandi Limestone[35]. The specimens of conodonts were in fact commented upon by Professor David L. Clark from Wisconsin. This error crept in inadvertently, and I apologize for it.

Dating rocks is a difficult business, and one in which anomalies often arise. For example, the Krol–Tal sequence of the Himalayas was for a long time thought to be Permian–Jurassic in age but is now established as Cambrian. Mistakes were certainly made over the record of different types of fossils from the Krol and Tal formations[36].

Let me pose this challenge to the veracity and verifiability of Dr Talent's claims.

(i) Will he defend his identification of *Linoproductus* and its alleged time range for the Krol Formation? (ii) Will he at last publish the scientific results of the large fauna he was allowed to collect and take to Australia over 15 years ago from the Bijni Tectonic Unit, Garhwal Himalaya, and other regions? (iii) Will he acknowledge that I, with another palaeontologist, published a systematic study on some fossils from the same area[37]? Will he admit that this paper has scientific validity? (iv) Will he acknowledge that faunas I described from the Fenestella Shales of Kashmir came from the Fenestella Shales of Kashmir[38,39]? (v) Is he willing to spend time at the Geological Survey of India and examine some of the rocks and fossils in question?

Talent[1–3] proclaims that I have been able to fool all of the people all of the time. The period concerned is a quarter of a century, and the number of people — all of them highly regarded palaeontologists — more than 60. The contention is unbelievable. Talent himself points out that it is impossible for one person to have a detailed knowledge of so many diverse faunal assemblages. That is precisely the reason why I collaborated with so many experts, and in doing so served geology by bringing to them fossils they could not collect personally.

John Talent has made sweeping pronouncements on Himalayan geology. Yet he is not an authority on the subject. I can only conclude that his attack on me was made for two reasons — to draw attention to himself and to deflect criticism of his own failure to contribute to Himalayan geology. □

The peripatetic fossils: part 3

The articles printed below are by co-authors of some of the papers called into doubt by Talent. Two are by close colleagues of Gupta at the Centre of Advanced Study in Geology at Panjab University.

Upper Palaeozoic of Lahul–Spiti

A.D. Ahluwalia

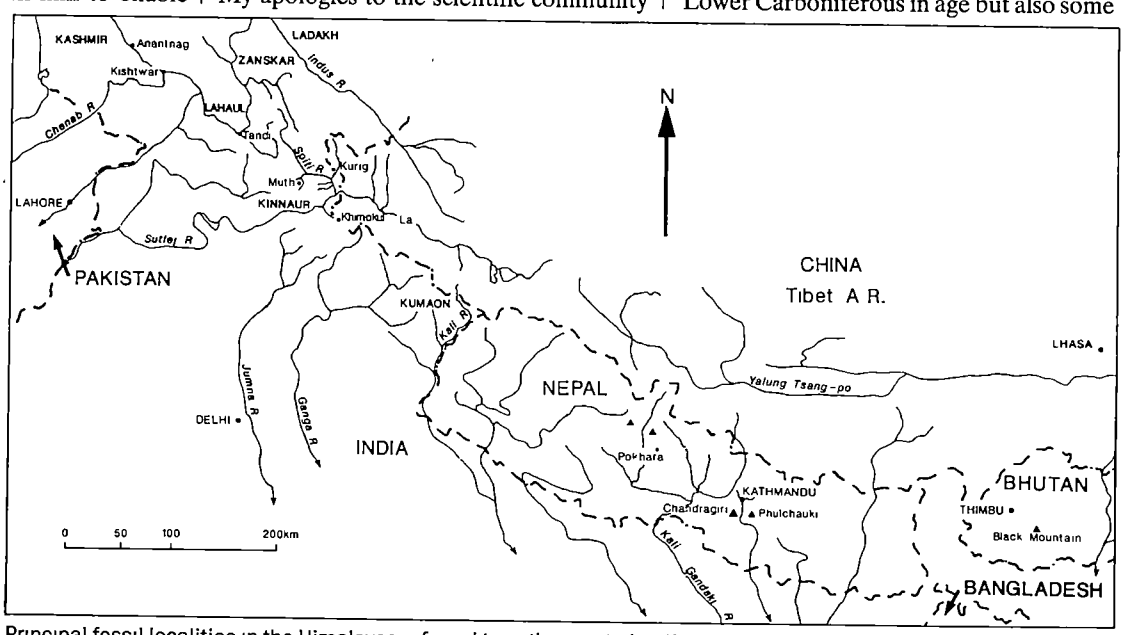
I was a member of five expeditions in the Himalayas (1977–81) organized by the Geological Survey of India (GSI), and one from Panjab University in 1988, and have an intimate knowledge of the Lahul–Spiti region. I am now a colleague of Professor Vishwa Jit Gupta at Panjab University. Most of the doubts expressed by Talent[1–3] are well-founded I would like to start the process of putting the record straight by pointing out some significant anomalies in the Upper Palaeozoic of Lahul–Spiti.

Devonian

In 1978, during a GSI mapping assignment, I measured and sampled the Takche–Muth–Lipak section in the Takche nala near Losar in the Upper Spiti Valley for micropalaeontological studies[4]. A part of the sample representing dolomitic limestone (20 cm), lying 5.9m below the Muth–Lipak contact in this section, was macerated in the local GSI laboratory. I had no experience with Devonian conodonts, but the part of the residue I examined was apparently barren.

In 1980, K.J. Budurov, a reputed Bulgarian conodont expert, visited the Panjab University. I took the residue of this sample to Gupta, Budurov's host, so that it could be examined afresh by the visitor Gupta suggested that the residue bottle should be left with him to enable him to spend some time on it before showing it to Budurov, and later Gupta pointed out the presence of numerous conodonts in the residue. I felt rather embarrassed at having initially missed the assemblage, but was happy at the 'discovery' which was jointly published with Gupta, Budurov and Kanwar[5,6].

On reading this year that the fossil assemblage had characteristics of the North Evans conodont fauna, and that it was considered to be anomalous for the Himalayas[1,2], I macerated afresh the part of the Muth dolomitic limestone sample that I had kept for further work. To my utter shock, I found this sample completely barren and Talent's doubts confirmed. Colleagues in GSI, who had independently looked at this sequence in 1982–83, were also disappointed. Budurov, who had taken parts of residues of my samples from this sequence in 1980 directly from me, conveyed absolutely negative results when returning the sample tubes through Gupta in 1985.



I am thus left wondering how a rich conodont assemblage, exactly like that of North Evans, had appeared in a sample which was indeed barren. There was no reason for suspicion at that time. Yet my trust seems to have been betrayed. With hindsight, one could say that I should have remacerated the sample in 1980. It is a great embarrassment for me now to officially withdraw these reports[5,6].

Though regionally impersistent, limestone layers are well established in the lithostratigraphy of the Takche section[4,7]. The Muth–Lipak lithocolumn[6] which was later borrowed and published in another of Gupta's papers[8], is the only reliable information which survives this unfortunate episode. In view of the above, the other reports of Devonian conodonts from the Himalayas[9–15] also become suspect. My apologies to the scientific community for this temporary indiscretion and also to Professor A. Gansser and H.M. Bolli and their *Diplomarbeit* students at ETH Zurich, to whom I demonstrated this assemblage in 1984 with an erroneous Spiti Himalayan label.

Carboniferous

(1) In 1977, I found a well-preserved crinoid in the Lower Carboniferous Lipak Limestone at Bindi–Paharıya on the right flank of the Chandra Valley in Lahul. This was during the GSI expedition on the right side of the Chandra, downstream of Bara Lacha Ban. The crinoid-bearing part of the huge sample was taken out by Gupta, who promised to have it examined by Professor G.D. Webster. After a short span of two weeks, Gupta conveyed Webster's opinion that the crinoid was "inconsequential". He promised to dig out the letter written by Professor Webster but somehow could not. After several years, however, a description of a crinoid resembling mine, and even having a similar crack running through it, was published as from "near Surichun La" (ref. 16). My misgivings were also aroused by the presence of the Po Formation at Surichun La instead of the Lipak Formation.

(2) In 1977 Gupta had suggested to me that I should look for conodonts in the part of the samples of Lipak Limestone that I had retained. His suggestion was a good one, and I did indeed find conodonts in my samples, not only some that were Lower Carboniferous in age but also some

Principal fossil localities in the Himalayas referred to in these articles (from Talent, ref 2)

from the Lower Triassic. I expressed my gratitude to him for his advice. But before I could report these conodonts from either area, Gupta published a note on Carboniferous conodonts from "Bara Lacha Ban" (ref. 17). He even mentioned getting similar material from Losar (Spiti) and also Kinnaur (the latter are still unpublished) Gupta was in fact told about Bara Lacha Ban in reference to Lower Triassic conodonts and he obviously seems to have got mixed up. Gupta had last crossed Bara Lacha La in 1969 with a big team[18], and as late as 1975 (ref 19) he had shown Cambro–Ordovician rocks in a geological map of this area and even Bara Lacha Ban. One can be absolutely sure that he had not been to Bara Lacha Ban, for there only the sequence from Po up to the Triassic limestone is exposed and the Lipak Formation in which he claimed to have discovered Carboniferous conodonts had been cut off by a fault[20,21]. Gupta was a co-author, with Budurov and Kanwar, of my preliminary reports on conodonts from these two localities[21,22], but his own Carboniferous conodont reports now started to come from near Losar[8,23]. He vaguely fixed the sample horizon in a lithocolumn prepared by me, but he completely ignored the fact that the Lipak Formation near Losar represents an intertidal–supratidal sequence, which has prominent evaporitic facies in parts and is not suitable for conodont occurrence. The Losar section has in fact never yielded conodonts in any of the samples checked by me, by colleagues in GSI or by Budurov. Nothing was ever heard from Budurov of our valuable conodont assemblage taken by him to Sofia in 1980 for detailed publication following the preliminary notes[21,22,24]. Two of my Lower Carboniferous conodonts that were given to Budurov, however, appeared in a paper by Gupta[23], who stated that they came from Losar and not from Bindi–Paharıya, their real locality[22]. Which locality the rest of the conodonts have come from seems to be fit for a game of guessing. It has been recently pointed out by Talent and several co-authors[25], that seven conodont specimens, illustrated a decade earlier from the Carboniferous of Ladakh[26], reappeared in a paper of 1986 (without the co-author) and were said to be from Losar[8]. Gupta points out similarities of this conodont fauna with that of several countries[8]. One can only hope that like the coral specimens from Wales[25], resemblance here also does not imply that the conodonts actually come from these countries.

(3) The documentation of some coral specimens of Carboniferous age from "near Surichunla" (ref. 27) and "Baralacha Ban" (ref. 28) by Gupta alone, and a later redocumentation from "near Tanze" (ref. 29), this time with Professor M. Kato of Japan, has raised new dimensions to the recycling of specimens. Only Gupta can say what is the genuine provenance of these corals, but in the light of the above one can rule out an occurrence at Bara Lacha Ban[20,21] It also remains to be stated precisely how "near" the alleged occurrence is to Surichun La and Tanze in Ladakh (refs 27, 28). Under these circumstances, even the supposed dates of collection of the samples would be of interest.

Permian

(1) The description of Permian limestone or Sarchu limestone from near Sarchu bridge[30] has been found to be untenable by all later workers, not only at the locality mentioned but also in the detailed regional surveys which established the absence of any Permian limestone in the Zanskar, Lahul–Spiti and Kinnaur regions. Triassic and Jurassic rocks were found at Lach Lung La[31] where Gupta had reported *Eurydesma*. The "Malung Shale" from which Gupta[32] reported *Eurydesma cordatum* (Early Permian), is reported to yield typical Upper Triassic fossils[33]. Yet Gupta and Waterhouse[34] not only wrote another paper reporting *Eurydesma* from the Malung Shale in Ladakh but later followed it up with a report of *Eurydesma cordatum* from the diamictite succession "forming transition between the Po Series below and the Kuling Series above": that is, the Ganmachidam Formation (Upper Carboniferous). This claim is contradictory, for *Eurydesma* has never been reported from anywhere below the level of the Gechang (Kuling) Formation — if Waterhouse and Gupta[34] are to be believed, one would end up having a typical index fossil occurring at two distinct and widely separated stratigraphic levels and also have the supposed fusulinid-bearing Sarchu Limestone occupying the level between the two! It is not clear whether it is Gupta or Waterhouse who is credited with collecting the samples, but the description of the *Eurydesma* locality as "exposed near Ganmachidam (left bank of the Kibijima nala stream) and Losar" (ref. 34) is ridiculous; Ganmachidam is situated in a meadow on the right flank of the Spiti river and not on the "left bank of Kibijima nala" which is a tributary of the Spiti quite some distance away.

(2) Gupta's report of *Popanoceras*[35] from "brown to greyish brown sandstone beds exposed in Savita nala near Losar" is not only palaeontologically anomalous but it also is not in conformity with the geological details on the ground. If all his claims are to be believed, this Middle Permian fossil is now found almost at Lower Permian or Upper Carboniferous levels. His locality is defined very imprecisely and a lithocolumn is not given, and yet he seeks to re-identify the stratigraphic horizon in the area as Gechang instead of Ganmachidam! I re-checked this locality, which is very near to the Losar Rest House, only in August–September 1988. "Near Losar in Savita nala", only the lower Middle Carboniferous Po Formation is exposed. High up on the flanks, but far from Losar and nearer to Ganmachidam, one finds lower parts of the Ganmachidam Formation. Could one really ever obtain Middle Permian or Lower Permian index fossils from an Upper Carboniferous sequence? Likewise, the stratigraphic position of the Ganmachidam Formation described by Gupta and Waterhouse[36] is full of contradictions and speculations.

Gupta is known to have been to Losar in the Upper Spiti Valley only once, in 1965 with S.P. Jain. There have been confusing reports about visits by J.B. Waterhouse to parts of Spiti and Kinnaur. Only Waterhouse can clarify his exact contributions to

so many vague and highly anomalous reports from the Himalayas[34,36–38], which are unlike his works from other areas Until 1988 no foreigners were allowed into Spiti, and when they were allowed to do so (as were Talent, Fuchs and a few others) they had to be accompanied by Indians.

Allegations of recycling of fossil specimens by assigning fictitious locality labels, or using foreign materials once housed in foreign museums[25] to illustrate 'new discoveries' from the Himalayas, are indeed serious and are being treated as such at Chandigarh, contrary to the report by Jayaraman[39]. Not only Gupta but also Waterhouse must speak up honestly and boldly, and address the grave charges point by point, as the issues involved can no longer be evaded. □

Early Devonian ostracodes

S. B. Bhatia

I WOULD like to take this opportunity of placing on record facts concerning the precise locality from which the Early Devonian ostracodes, reported by myself and my colleagues V.J. Gupta and S.P. Jain[1], were collected, and to which Talent referred in his Commentary article. I was a member of the expedition (along with Gupta, Jain and R.C. Kanwar) which visited the Spiti Valley in 1966, and in the last leg (on which Jain was not present) I collected samples from near Kurig, close to the India–Tibet border. But the sample in question (containing ostracodes) was not collected by me. I also do not recollect Gupta collecting samples from that area.

However, several years later, in 1972, when I was about to visit Britain under a British Council Exchange Programme, Gupta handed over to me a small vial containing some washed residue and asked me to have a look at the ostracodes it contained during my stay at the British Museum (Natural History). Gupta stated that the sample was from near Kurig, without being precise, and of Devonian age. My own observations in the field diary, however, were that the rocks around Kurig were of Permo-Carboniferous age. I accepted Gupta's statement in good faith, presuming that I had missed the band containing Devonian ostracodes.

While working at the BM(NH) I was struck by the close similarity and even match, at the specific level, of the material provided by Gupta and the material from the Haragan Formation, Oklahoma, housed in the BM(NH) Accordingly, a slide containing representative ostracodes was sent to Dr Lundin of Arizona State University for his comments, and he too was impressed by the similarity of the Spiti and Haragan faunas.

Be that as it may, as a sequel to the controversy raised by Talent it became imperative for me to recheck the possible match of the Spiti and the Haragan ostracode faunas Accordingly, I requested Lundin (in a letter of 12 April 1989) for some comparative material from the Haragan. I await that material, but can quote from Lundin's letter of 2 May 1989:

> . . I have followed the controversy brought on by Gupta's discoveries and the article by Talent with great interest especially because of the ostracodes you sent me in 1972. I recall that I was especially impressed at the similarity of the fauna you sent me with the Haragan fauna I described in 1968. The species constitution and even the state of preservation of your fauna and the Haragan fauna, as I recall, were remarkably similar. Scientists are skeptics! As well they should be. I regret that your name has been tarnished. . . .

The facts mentioned above are being communicated so that the scientific community may know the truth regarding the worth of 'Devonian ostracodes' from the Himalayas in the context of the controversy regarding the authenticity of Gupta's research findings. As stated in the editorial on p.604 of the same issue of *Nature* as Talent's article, palaeontologists should, on this occasion, have been quicker to voice their doubts True, but then it is better to be late than never.

Finally, I should like to comment on the news story by Jayaraman which later appeared in *Nature*[2].

Jayaraman's contention that Gupta's colleagues at the Centre of Advanced Study in Geology, Panjab University, Chandigarh, consider Talent's allegations as a "conspiracy to denigrate a top Indian scientist" is not true. I, for one, reacted immediately to the controversy, and in a letter dated 27 April 1989, addressed to our Vice-Chancellor, I suggested that a fact-finding committee should be set up to get to the truth. In fact, as stated in this letter, I am firmly of the opinion that the only way in which the scientific community will be convinced of Gupta's research findings will be for Gupta to invite some Earth scientists to accompany him to a few of the controversial localities in the Himalayas and prove the authenticity and reproducibility of his fossil finds. This is the only way Gupta can redeem his reputation as well as the fair name of our university □

The Kinnaur region

Udai K. Bassi

THE Kinnaur region of the Himalayas is the subject of some of the questionable papers discussed by Talent. This inhospitable and rugged terrain was systematically mapped and investigated by myself and my associates during nine expeditions (1978–86), each expedition lasting over a hundred days. Based on my intimate knowledge of Kinnaur and part of Spiti, I make the following observations on publications dealing with this area.

(i) It would be impossible to obtain the Devonian ostracode fauna[1] from Kurig, for in this area only Carboniferous rocks are exposed[2].

(ii) The report of Late Devonian vertebrate remains[3] from the Yulang section states: "Muth Quartzite passes up into a 50 m thick succession of shales with thin bands of quartzite followed by a 200 m thick horizon of siliceous and shaly limestone". Another paper on the same area[4] states: "The Muth Quartzite in the Yulang River section is conformably overlain by 10 m thick succession of grey limestone forming transitional horizon between the Muth Quartzite below and Lipak Formation above". The lithostratigraphy in the two reports is not only contradictory but factually incorrect — the sequence in the Yulang section is inverted and the Muth is physically overlain by the Silurian Takche Formation. Moreover, Gupta reported the same conodont fauna (*Palmatolepsis, Polygnathus* and so on), from two limestone horizons separated by 50 m and resting above the Muth Quartzite[3,4]. The anomalies in lithostratigraphy and fauna levels render these two papers worthless.

(iii) The description of the geology of the Tidong Valley[5] surprisingly lacks a geological map and contains a borrowed lithocolumn[6]. It also omits details of the pre-Muth sequence, which is best developed in this section[7]. The report of sulcispiriferinids[8], ignoring the work of Chopra *et al.*[6] and referring to Gupta and Waterhouse[5] with a wrong title, is mystifying

(iv) The paper on the Fammenian ammonoids[9] post-dates all papers on Khimokul La yet it avoids all references to this work, even Gupta's own earlier papers. The "limestone" or "shale" bands referred to in the Muth Formation in this section are fictitious and do not exist in the field. The paper declares that the repository of the ammonoids is the Geology Department at Panjab University, but no registration numbers are given. Enquiry at the Geology Department revealed that these specimens were never deposited there.

The statement "Noric and Rhaetic suc-

cession is poorly fossiliferous and has not yielded any determinable fossil", attributed to Bassi *et al* (1980) by Gupta and Waterhouse[5], is a misquotation. I have never made such a statement, nor does such a publication exist The report of Carnian conodonts[10] from the Khimokul La cannot be true as no rocks younger than Lower Triassic exist at this pass on the Indo-Tibet border Dr O. N. Bhargava and I went to the base of Khimokul La in 1984 to sample the Silurian reef[11] and to check Gupta and Erben's report of ammonoids in the area[9]. The problem of the ammonoids apart, Gupta's, Erben's and Waterhouse's names do not figure in the register at the border post; anybody who wishes to go to Khimokul La has to pass through that post Further enquiries of local people revealed that neither Gupta nor any foreigner visited this valley, even the fringes of it.

I regret having published three palaeontology papers[6,12,13] with Gupta. Of these, the report of *Neogondolella regale*[13] has to be withdrawn because the lithocolumn supplied by me has been changed without my knowledge to increase the thickness of the Triassic by about 30 m, possibly to accommodate the Carnian conodonts[10] □

Breakdown of trust

Philippe Janvier

THE world community of palaeontologists should be grateful to Dr Talent for his work, Sherlock Holmes style, on 'anomalies' in Himalayan geology. As one of the numerous people who co-authored with Professor Gupta some of the papers in question, I would like to comment upon remarks made both by Talent and in the editorial article in the same issue of *Nature* (p.604).

Talent and several journalists who have written about this case question why so many reputedly good scientists have been taken in by these 'Himalayan' fossils. The process of being caught in such an affair involves both psychological and professional factors. The psychological factor is the trust one has in one's colleagues I would guess that 90 per cent of the published palaeontological data are based on trust in the field geologist who collected the fossils; when the fossiliferous localities are later revisited, the data are generally confirmed. Given this, most palaeontologists dare not even think it possible that their colleagues may have misled them. Even if they do so, they have a duty to wait for evidence. Presumptions alone are not sufficient.

The first I heard of reservations concerning Professor Gupta's fossils was in 1981, when I had written a paper with him about a most interesting Devonian sarcopterygian fish, supposedly from the Zanskar area of India[1]. The same year this fish turned out to be *Youngolepis*, known elsewhere from Yunnan (China) and North Vietnam.

Talent and colleagues suggest that the presence of this strongly endemic Chinese form in the Himalayas should have been regarded as unacceptable[2]. However, beside the fact that the Chinese example was undescribed when Professor Gupta brought me his specimen, the presumption of endemism cannot be regarded as a scientific argument to reject a finding. Endemism is untestable in palaeontology, and can be approached only by the accumulation of empirical data. Thus, although I had some doubts about the Himalayan origin of the fish, I could only express them, in an additional note, by saying that it was strikingly similar in aspect, colour and matrix to the specimens from Yunnan. Moreover, all the reservations I had heard at that time about Professor Gupta's work sounded like gossip, and I was not prepared to take them seriously until they appeared in print and until Professor Gupta had had the opportunity to defend himself.

French geologists still feel guilty about the Deprat case in the 1920s, when the French field geologist J. Deprat, Head of the Service Géologique de l'Indochine in Hanoi, was accused of having misattributed specimens after finding particular trilobites in Yunnan Deprat was fired and banned from the Geological Society of France (he later became a novel writer and even wrote a symphony). Some years later, the trilobites in question turned out to be exactly at the right place. The basis for the accusation against Deprat was that the trilobites belonged to the 'Barrandian' fauna of western Europe, and that some specimens were glued with the same glue as used in the collections of the School of Mines in Paris

In sum, the reason why Professor Gupta could continue to travel around the world with his 'Himalayan' fossils is that, until the appearance of Talent's article, those who were really aware of problems in Himalayan stratigraphy and tectonics never expressed their doubts in print, and in an unambiguous way. After my experience with the 'Zanskar' fish, I have never published on any fossils I have not collected myself, unless they have been deposited in a museum that can warrant their origin.

Talent describes some of the professional factors behind occurrences such as these. One is the need to publish as many papers as possible in order to become 'famous'. Many professional researchers in palaeontology do so because they are required to do so! Some write virtually the same paper in different languages, others publish accounts of a particular fauna, group by group, sometimes fossil by fossil. In France, researchers are encouraged to do this. The reason is said to be that such an approach makes easier the evaluation of the thoroughness and diligence of the work of a researcher or of a research team. In reality, it facilitates the work of the committees that have to promote researchers: instead of reading the papers, it suffices to count them. I guess that this practice is not unique to France. Clearly it works in India too.

Finally, I would like to stress the difficulty of defining what is a fraud in palaeontology. In the press, the Gupta case has been compared with that of Piltdown Indeed, in both instances the fossils did not originate in the locality they are supposed to have come from, and the only difference is that the Piltdown site is more accessible than the Himalayan valleys.

But there are all kinds of gradations in wrong-doing and some misdemeanours are far less obvious than others. All of us know of slightly distorted facts or measurements that can be accounted for as simple mistakes, but that have important bearings on the conclusions that are drawn from them. The abundant literature on mass extinctions, for example, is full of such examples, which will never be regarded as true frauds. I am sure that some parts of the literature on molecular biology are flawed with similar cases. These belong to the 'noise' in the history of science. The Gupta case may just be a 'big noise' □

NEW FROM

OXFORD

An Introduction to the Optical Microscope

NEW EDITION

Revised Edition

Savile Bradbury

'... well written, clearly illustrated and eminently readable ... should help all microscopists ... obtain the best possible results from their instruments.' *Journal of Biological Education* on the first edition

Royal Microscopical Society Microscopy Handbooks No. 01
0 19 856419 8, 92 pp., illus., paperback, June 1989 £4.95

RMS Dictionary of Light Microscopy

Nomenclature Committee of the RMS

This dictionary makes recommendations for current usage, international standards, and gives the origins and meanings of the words involved in the field of light microscopy.

Royal Microscopical Society Microscopy Handbooks No. 15
0 19 856421 X, 150 pp., illus., May 1989 £15.00
0 19 856413 9, paperback, May 1989 £6.95

Colloidal Gold

A New Perspective for Cytochemical Marking

Julian E. Beesley

This book describes the established techniques of gold probe production and of immunolabelling. Each technique is summarized in a table which can be used in the laboratory separately from the text.

Royal Microscopical Society Microscopy Handbooks No. 17
0 19 856418 X, 64 pp., illus., paperback, March 1989 £5.95

Autoradiography: A Comprehensive Overview

John R. J. Baker

Autoradiography is the localization within a solid specimen of a radiolabel by placing the specimen against a layer of detector material. This book describes the major techniques in a simplified but comprehensive manner.

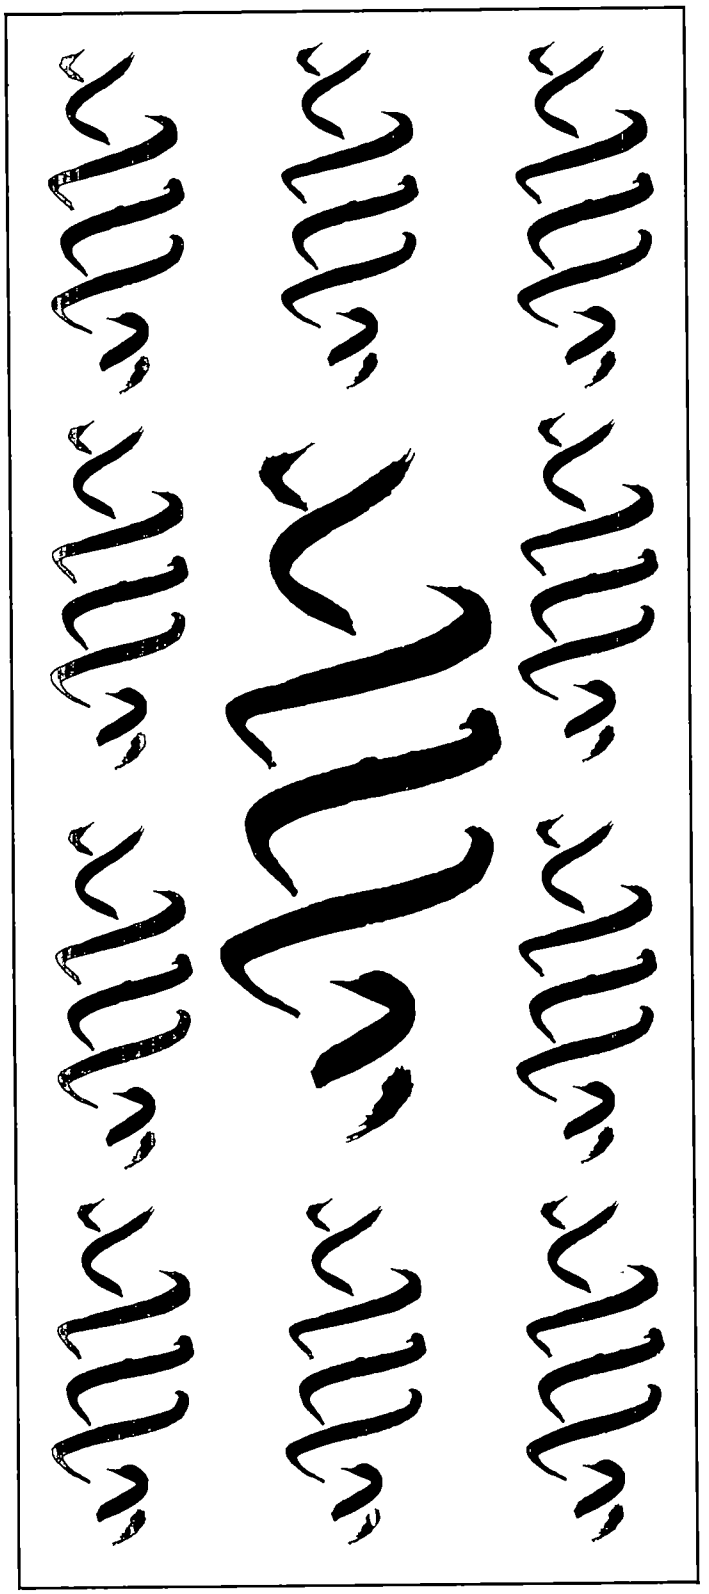
Royal Microscopical Society Microscopy Handbooks No. 18
0 19 856422 8, 120 pp., illus., paperback, August 1989 £9 95

Light-Element Analysis in the Transmission Electron Microscope

WEDX and EELS

P. M. Budd and Peter J. Goodhew

A simple, practical handbook to using the transmission electron microscope for routine analysis of the light elements. Both X-ray analysis without a window (WEDX) and electron energy-loss spectroscopy (EELS) are described.



Royal Microscopical Society Microscopy Handbooks No. 16
0 19 856417 1, 80 pp., illus., paperback, 1988 £6.95

WHEN IS A GENE NOT A DESIGNER GENE™

WHEN IT'S A cDNA CLONE

Designer Genes™ are double stranded and fully sequenced. A 100% SEQUENCE GUARANTEE means that every Designer Gene™ is supplied with NO MUTATIONS.

With USEFUL ENGINEERED RESTRICTION SITES at 5' and 3' ends, as well as throughout their length, Designer Genes™ make genetic manipulation simple.

Designer Genes™ are suitable for expressing proteins, structure-function studies of protein variants or as a source of hybridisation probes, and since they are available from stock you will receive your gene WITHIN DAYS OF ORDERING.

Knowing all of this can you afford to trust your research to an uncharacterised cDNA clone?

Designer Genes

INTERLEUKINS	HUMAN IL-1α,β, 2, 3, 4, 5, 6, 7 and 8
	MURINE IL-3, 4, 6 and 7
GROWTH FACTORS	GM-CSF, G-CSF
	TNFα,β
	EGF
	FGF acidic and basic
	PDGF A and B
	IGF I and II ...
	and many more
VIRAL COMPONENTS	HIV-1 Protease
	HIV-1 Regulatory Genes

Is chaos becoming conversational?

Most accounts of chaotic dynamical systems are based on numerical computations of some kind. But now there is a welcome sign that verbal arguments may make these studies more accessible.

THERE is something waywardly biblical about the ambition to make order out of chaos, but there is nothing wrong with wishing to engage in conversation about the concept of chaos in dynamics even if one happens to be so disadvantaged as not recently to have had access to a Cray II. That thought will be provoked in the minds of many who stumble on a fascinating paper called "Routes to chaotic scattering" in the issue of *Physical Review Letters* for 28 August (**63**, 919; 1989).

Chaos in dynamics is a simple concept now much popularized, often for the wrong reasons: there are circumstances in which the solution of the equations describing real problems in dynamics depend sensitively, sometimes exquisitely so, on the initial conditions. The result is that identical particles starting from virtually indistinguishable places in phase space (the join of position and velocity) will rapidly drift apart from each other. Those who work in the field and the Cray II seem to have been made for each other, for most of what is known about chaos is numerical.

What S. Bleher, E. Ott and C. Grebogi from the University of Maryland have done in their article will encourage those with different inclinations. Their arguments are in the main verbal, and almost analytical.

Their problem, which evidently should have been taken up much earlier, is simply that of the scattering of classical particles (otherwise 'billiard balls') by a potential surface, a region of space in which a particle has extra potential energy and from which it is therefore repelled. That such a system should be capable of chaotic behaviour is easily appreciated: even in the over-simple representation of a scattering centre by a billiard ball, the outcome of a scattering event is too often an inconveniently sensitive function of the impact parameter (the offset of the direction of travel of the particle and the parallel line through the centre of the target), as billiards players know all too well.

For kinds of scattering centres other than rigid hard spheres, the behaviour of impinging particles can be more complicated. For example, in nuclear scattering (still classical), there is supposed to be a region of space in which the potential energy is spherically symmetrical about some point (the nucleus). The potential increases steadily as the scattering centre is approached and will then be a maximum, say E_m. Rutherford was the first to calculate the scattering angle as a function of the impact parameter.

In this simple case, chaos does not arise. Indeed, if the energy, E, of the impinging particles is greater than E_m, it is easy enough to guess what the graph of the scattering angle against the impact parameter will be. When the impact parameter is very large and, alternatively, zero, the scattering angle will be zero: particles whose paths are a long way from the scattering centre will not be deflected, whereas those aimed directly at the centre will also go straight through, but there will be some intermediate impact parameter for which the scattering is a maximum, but the maximum angle must be less than $\pi/2$. The case when E is less than E_m is more complicated, for particles aimed directly at the scattering centre bounce right back, but chaos does not arise.

But what if the scattering centre is not a simple potential-energy peak, but a group of several of them? This is the problem that Bleher and his colleagues tackle, for simplicity in two dimensions. As a numerical example, they describe what happens when the potential energy is a simple function of the coordinates of the form $x^2y^2\exp[-(x^2 + y^2)]$, which is really a system of four equal peaks in the potential-energy surface. When E is greater than E_m, again there is no difficulty; the scattering angle is a more complicated function of the impact parameter, but still smooth. But if the energy is less than the maximum, the system lapses into chaos. What happens is that particles are trapped within the system, bouncing repeatedly between the energy maxima before eventually escaping in a direction that is exquisitely sensitive to the manner in which they were originally captured.

What can be said in words about such a complicated problem? A great deal, it seems. The authors take the general case of an array of three scattering centres whose energy maxima are E_{m1}, E_{m2} and E_{m3}, arranged in order of increasing size. Two cases arise, the authors say, depending on the geometrical relationship of the scattering centres. Either the weakest of the three lies outside the circle whose diameter is the line joining the other two, or it lies inside that circle. The essence of the distinction is that, in the first case, the angle at the apex of the triangle joining the three scattering centres must be less than $\pi/2$, but otherwise is greater than that. The problem is to predict when and how particles impinging on this system will behave chaotically.

Chaos plainly cannot arise unless E is less than E_{m2}, for then there is no way in which the particles can be trapped into orbits bouncing between a pair of scattering centres. And, in this case, because the maximum scattering angle at the lowest peak must be less than $\pi/2$, a particle scattered from say E_{m2} towards E_{m1} cannot be scattered back towards E_{m3}. But once the energy of the incident particles falls below E_{m1}, an infinite number of trapped orbits is accessible, simply because larger angles of deflection are immediately possible. There is an abrupt transition from order to chaos.

The second case, where the scattering centre with the smallest energy lies within the circle, is more complicated. If E is greater than E_{m1} but less than E_{m2}, everything hangs on whether E_{m1} is large enough to deflect a particle arriving from one of the other scattering centres towards the third. If so, there will again be an immediate transition to chaos, for an infinite number of nearly periodic bouncing orbits will be accessible to particles. If, on the other hand, E_{m1} is insufficiently large for that, there will still be trajectories in which a particle first scattered by E_{m1} will be trapped for less or more time between the other two centres. The number of these orbits will multiply rapidly as E is reduced below E_{m2}, but in a manner exactly like the appearance of chaos in more familiar chaotic systems, by the process called bifurcation (equivalently, 'period-doubling') in which extra allowable orbits make their appearance as some parameter is varied.

The result is simple enough, but plainly applicable to much more complicated arrays of scatterers. To those working in the field of chaos, much of the interest will lie in the authors' demonstration that chaos can arise in the same dynamical system in two distinct ways — either abruptly, or by the more familiar bifurcation route. For what it is worth, their calculation is that the fractal dimension of the number of chaotic orbits varies as they expect with the difference between E and the energy of the scattering peak. But, to others, it will be enlivening that the authors have been able to make their intricate argument almost verbal. Those without an allocation of time on a Cray II will be pleased.

John Maddox

MALARIA

Binding of infected red cells

Louis H. Miller

NEARLY a century ago, Bignami and Bastianelli noted that red cells infected with the malaria parasite, *Plasmodium falciparum*, disappear from the peripheral blood. It has since emerged that they are sequestered along the smaller blood vessels, by which means the parasites are protected from the lethal immune activity of the spleen. That same process is responsible for many of the complications of

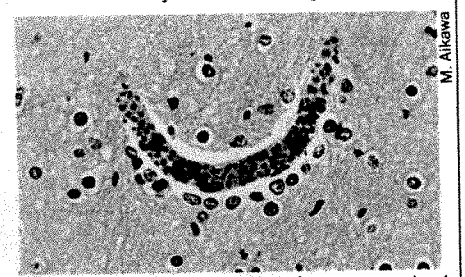

FIG. 1 A cerebral capillary from a cerebral malaria patient. The capillary lumen is obliterated with infected red cells.

severe malaria and for much of its mortality. Thus the placentae of fetuses carried by infected mothers are filled with parasitized red cells, which may contribute to low neonatal weight and to high maternal mortality (especially in a first pregnancy), whereas infected red cells bound to vessels in the brain (Fig. 1) may account for the high death rate in cerebral malaria, which is well in excess of 20 per cent.

These facts give sufficient reason for the exploration of the molecular basis of the cytoadherence of infected red cells, now well under way. Berendt *et al.*, reporting on page 57 of this issue[1], have identified intercellular adhesion molecule-1 (ICAM-1) as a third cell-surface receptor for infected red cells; furthermore, the authors have demonstrated that different parasite clones stick to different receptors — cytoadherence is heterogenous. In due course, that could lead to novel therapies for some of the complications of malaria.

The molecular mechanism by which infected red cells, exploiting knob-like protrusions on their membranes (Fig. 2), bind to the surfaces of venules can be studied because of continuous-culture methods for *P. falciparum*[2] and *in vitro* techniques for the study of cytoadherence[3,4]. Most work in the field has so far relied on human umbilical endothelial cells[3] and a melanoma tumour line[4], but the expression of specific membrane proteins in transfected cells, as with the expression of ICAM-1 in COS cells[1], which transiently express genes at high level, is a more direct route to understanding the details of specific binding.

As yet, there is no direct proof as to which molecules on the red-cell surface mediate attachment to endothelium — one candidate is immunoprecipitated by strain-specific sera[5] that also block cytoadherence in a strain-specific manner[6]. By contrast, the new report brings to three the number of identified host proteins to which infected red cells bind. One is the soluble protein thrombospondin[7], another is CD36 (see refs 8,9) which, like ICAM-1, is a surface membrane protein expressed on specific cells. Binding has been demonstrated either to isolated protein or to cells transfected with the appropriate gene.

Several questions are provoked by this multiplicity of host binding proteins. Are parasitized red cells generally sticky, binding to several proteins? If so, do these proteins have a common group at which binding takes place? Otherwise, what is the physiological significance of the parasitized red cell's capacity to bind to three different host proteins? Which of these, if any, are involved in the sequestration of parasitized red cells to endothelium in uncomplicated malaria, to cerebral vessels in cerebral malaria and to the placenta? Binding to various melanoma-cell lines correlates with the expression of CD36, but that does not define the mechanism of binding in human beings.

The study by Berendt and colleagues[1] marks a start on the unravelling of that problem. Different *P. falciparum* clones, ITO4 and FCR3, are shown to bind to different molecules. But the observation that ITO4 clones bind to COS cells separately transfected with ICAM-1 and CD36, and that FCR3 clones bind only to the latter, in itself suggests that there are least

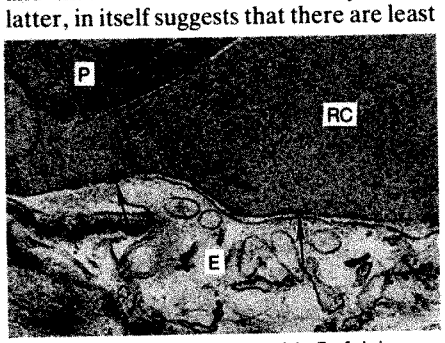

FIG. 2 A cerebral capillary with *P. falciparum* (P)-infected red cell (RC) adherent to the endothelial cell (E) by knobs (arrows). (From ref. 14.)

two distinct binding mechanisms and that red cells, as modified by parasites, do not recognize determinants common to the two host receptors. That is consistent with the absence of homologous regions in the amino-acid sequences of ICAM-1 and CD36. The binding specificity of parasites from patients with cerebral malaria will be awaited with great interest.

The cytoadherence molecules on parasitized red cells would be another part of the story, but perhaps only a part. In animal models, *P. falciparum* sequesters not in cerebral vessels, but in venules elsewhere in the body[10]. Cerebral malaria caused by the rodent parasite *P. berghei* is associated with macrophages and parasitized red cells in the cerebral vessels, and tumour necrosis factor (TNF) has been shown, by antibody blocking experiments, to have a role in the disease[11]. Although macrophages are not found in the cerebral vessels of people with cerebral malaria, seriously ill patients have markedly high levels of TNF (ref. 12).

Given that cultured human endothelial cells express ICAM-1 on the addition of TNF, it is possible that TNF (and other cytokines) may enhance the expression of molecules on the cerebral endothelium to which malarial red cells bind, with the consequence that cerebral vessels are obstructed. That implies that there is now a need to define the putative receptors on human cerebral endothelium when there is, or is not, cerebral sequestration. The outcome might be anti-receptor therapy to reduce the mortality from this dread complication of infection with *P. falciparum*.

The biology of the diversity of mechanisms of cytoadherence is also important. The evolution of cytoadherence, it must be recalled, has been driven not so that parasites can block cerebral blood vessels, but so that they may avoid circulation through the spleen. So why are there several parallel mechanisms? It is a little like the diversity of mechanisms for invasion by parasites, where the pathway used is determined by the characteristics of the red cell and of the parasite clone; *P. falciparum* merozoites may invade red cells by pathways that are dependent on, or independent of, sialic acid, for example[13]. The diversity of receptors both for invasion and cytoadherence may enhance the success of each, thus increasing the chances of survival of parasites living in the blood under continuous immune attack. □

Louis H. Miller is at the Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland 20892, USA.

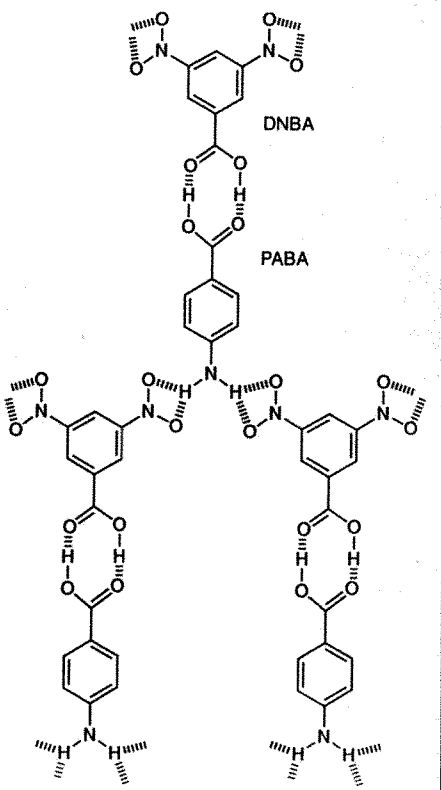
ORGANIC CRYSTALS

Losing symmetry by design



Kenneth D. M. Harris and Mark D. Hollingsworth

CRYSTALLINE organic solids are becoming increasingly important for their optical, electrical and magnetic properties. In general, these depend not only on the properties of the constituent molecules, but also, sometimes critically, on the spatial arrangement of the molecules in the crystal. Progress in the design of molecular crystals with carefully tailored solid-state properties clearly relies upon an improved understanding of the factors that control crystal packing. Many successful, albeit largely empirical, strategies have been devised for engineering molecules to crystallize in controlled and predictable arrangements[1]. New advances in the 'crystal engineering' of hydrogen-bonded structures, discussed by M. C. Etter (University of Minnesota) at a recent conference*, are now enabling the design of materials with important nonlinear optical properties.

Hydrogen bonds are ubiquitous in organic crystals and, because they are often stronger than other intermolecular forces, they frequently control the molecular packing arrangement. By surveying the extensive crystallographic data in the Cambridge Structural Database, Etter and co-workers have developed a systematic rationalization of hydrogen bonding patterns. They used graph theory to classify recurring patterns in a large number of hydrogen-bonded structures, allowing them to establish a set of empirical rules to categorize the features of hydrogen-bonded linkages formed by various specific types of functional groups. As a result, it is now possible to predict, with a good chance of success, the probable mode of crystal packing of molecules designed to have strategically arranged hydrogen-bond donor and acceptor groups.

A principal goal for Etter's group is the design of frequency-doubling crystals. Because these crystals convert light of one frequency to light with twice the frequency, they can greatly increase the frequency range of lasers, and have numerous potential applications in the emerging field of optoelectronics. The parameter that characterizes the usefulness of an individual molecule for frequency doubling — otherwise known as second-harmonic generation — is its second-order hyperpolarizability tensor, denoted β.

Molecular features such as polarizable π-electrons, donor–acceptor conjugate pairs or long conjugated chains generally give rise to a large value of β. In a crystalline material, however, second-harmonic generation also depends on the spatial arrangement of the molecules. For example, a crystal cannot exhibit second-harmonic generation if its structure has a centre of symmetry, even if the constituent molecules have a large β. Further crystallographic criteria have been identified by Zyss and Oudar[2], and other factors, such as phase-matchability and absorptivity, also determine the ultimate usefulness of a material for frequency doubling.

The co-crystal of *p*-aminobenzoic acid (PABA) and 3,5-dinitrobenzoic acid (DNBA) comprises a stacking of layers of the type shown. Each layer contains an extensively hydrogen-bonded, non-centrosymmetric arrangement of the molecules. (The hydrogen bonds are indicated by dashed lines.)

Unfortunately, although in some ways predictably, many molecules that have a large value of β tend to crystallize spontaneously in centrosymmetric structures: hence the interest of Etter and others in developing crystal engineering strategies to induce such molecules to adopt acentric structures. Etter points out that a single hydrogen bond is intrinsically non-centrosymmetric so that non-centrosymmetric arrays can be constructed from judiciously designed molecular building blocks joined by strategically positioned hydrogen bonds. In designing materials suitable for second-harmonic generation, the approach is to choose a molecule with features promoting a large value of β, and to arrange hydrogen-bond donors and acceptors in positions that promote non-centrosymmetric aggregation.

One notable success of this strategy, reported by Etter and Frankenbach earlier this year[3], is the co-crystal of *p*-aminobenzoic acid and 3,5-dinitrobenzoic acid, which has the packing depicted in the figure. As predicted, the molecules form a non-centrosymmetric, two-dimensional sheet which is held together by an extensive network of hydrogen bonds. The stacking of these acentric, polar layers is harder to predict: the individual layers are, in fact, buckled so that they stack on top of one another with translational symmetry. The polarity of the layer is, therefore, transferred to the crystal as a whole and the material is capable of second-harmonic generation. (Unfortunately, the molecular dipole and a crystallographic 2-fold axis coincide, resulting in a loss of phase-matchability, and hence of performance.)

Several other approaches for inducing molecules into non-centrosymmetric environments are being explored. For example, thiourea inclusion compounds containing certain organometallic complexes — such as (η^6-benzene)Cr(CO)$_3$ — can give pronounced second-harmonic generation[4]. The pure (native) crystalline phases of these organometallic materials are centrosymmetric and therefore incapable of second-harmonic generation, but when included within the linear tunnels of their thiourea inclusion compounds, they adopt a non-centrosymmetric head-to-tail dipolar alignment. The inclusion of an organic molecule (*p*-nitroaniline) within an acentric aluminophosphate molecular sieve (ALPO-5) has also been used to produce second-harmonic generation[5].

Another important study[6] has shown that 'guest' molecules occluded within centrosymmetric 'host' crystals can be selectively incorporated into certain symmetry related sectors of the crystal but not into others. Even extremely small amounts (0.01 per cent weight) of guest can lead to a sufficient lowering of the symmetry of the crystal for significant second-harmonic generation to be possible. □

PERCEPTUAL DECISION-MAKING

Watching neurons discriminate

M. J. Morgan

WHAT is the nature of the perceptual decision process in the brain when we recognize an object, distinguishing it from others — a cat from all dogs, for example? How many neurons are involved? How many neural stages are there between stimulus and response? These questions are tackled in a technical *tour de force* by Newsome, Britten and Movshon on page 52 of this issue[1]. The authors describe recordings from single neurons in monkey cortex while the whole animal makes a perceptual decision. Their conclusion is that perceptual decisions may be correlated with the activity of a small number of neurons, perhaps as few as one.

Expectations in this field are sharply polarized. In one theory of sensory processing[2], sometimes known as the 'grandmother cell' hypothesis, perceptual stimuli are categorized by means of a hierarchy of neural filtering mechanisms terminating in the activity of a set of neurons, each of which is associated with a particular object. Crudely, we recognize a cat when the firing rate is higher in the 'cat' neuron than in competitors such as 'dog' or 'rabbit'. The 'cat' neuron is the site of convergence of combinations of perceived attributes that reliably distinguish cats from other animals.

Those who believe perception to be a deeply complicated process find the grandmother-cell hypothesis too simple to be true. That is why there is no shortage of suggestions that perceptual classification depends on distributed activity among large populations of neurons, seamlessly connected with another large population of neurons by which our responses are determined[3]. In this model, there is a "distributed representation" of external stimuli; one would look in vain for single neurons whose activity is correlated with perceptual decisions.

Previous studies in this field have dealt with these issues only indirectly, by comparing the measured performance of single neurons and of whole animals, but under different conditions and not simultaneously. Thus the capacity of an individual neuron to distinguish between two stimuli can be measured by the difference between the number of spikes evoked by one stimulus and another; if the difference is statistically significant against the background noise of random neuronal firing, we may conclude that the neuron can distinguish between the stimuli. Analogously, but separately, the ability of a conscious monkey or of a human observer to distinguish between two stimuli can be measured by the magnitude of the difference between them that can be detected with statistical reliability.

The statistical criteria have the same meaning in the two approaches, and provide a direct comparison of the capacity of single neurons and of conscious observers to make perceptual decisions. Using this logic, for example, Parker and Hawken have shown[4] that the capacity of single neurons in monkey visual cortex to distinguish different positions of a line within their receptive field is similar to the ability of human beings and monkeys to report the direction of the displacement of a line in a binary decision task.

Newsome *et al.* break new ground by recording neuronal and whole-animal performance simultaneously. They have recorded from neurons in a monkey cortex while the animal is attempting a perceptual decision — that of identifying the direction of motion across a computer screen of a set of drifting dots embedded in a set of randomly moving dots (to complicate the task). Neurons were selected from the MT area of the cortex (otherwise V5), strongly implicated in motion processing in humans[5,6]. The first step is to determine for each neuron (60 in two monkeys) the 'preferred direction' of movement, for that in which the neuronal response is greatest. The monkey is then given the task of distinguishing, for each neuron, between motion in the preferred and the opposite direction. Its decision is inferred from the direction in which its eyes move.

The capacity of single neurons to discriminate turns out, in many of the 60 cases, to be as good as the whole animal's; some were even better. One way of thinking about this result is to imagine a contest between two human observers presented with the same task, one of whom is able to examine the spike trains of the neuron and the other only to look at the moving stimulus. Since the acuity of visual discrimination in human beings and monkeys is usually very similar, the results of Newsome *et al.* imply that the two observers would be correct equally often. The outcome of the contest would hang on the discriminatory capacity of the selected neuron whose spike train is accessible. The contestant with access only to the spike train might even win.

Two conceptually difficult questions are provided by their experiments. The first is the problem of identifying the level of processing at which a neuron is active. It is not immediately clear from the result reported so far whether the MT units are closest to the sensory input stage, the perceptual decision stage or the output stage. The standard engineering model of neural processing sees it as a cascade of stages beginning in the retina and ending with some overt behaviour. At each stage, noise can arise that degrades performance and which is uncorrelated with noise entering at other stages. It follows that if a neuron is found that has a better performance than the whole animal, it is nearer to the sensory-input stage than the final decision process.

Thus the important aspect of the experiment by Newsome *et al.* is not that neurons were found that correlated with the stimulus — this is trivial — but that they were no better than the whole animal. The fact that some were a bit better is an objection to treating them as decision units, as the authors note. In the remaining units, which were no better than the whole animal, the clearest evidence for a real relation between their activity and the decision process would be a trial-to-trial correlation between neural activity and the monkey's response when the influence of the stimulus *per se* was removed by methods of partial correlation. We could then be sure that the MT unit was on the watershed between stimulus and response, rather than too far towards the stimulus side.

It is possible, of course, that the MT units are merely output devices. That they might directly control eye movements (the monkey's signal of its decision) is ruled out by the time-lag between their activity and the movement of the eyes. The question of whether they betoken an intention is metaphysical.

The second deep issue provoked by the experiments of Newsome *et al.* is that of neuronal selection. Only a small population of neurons may be capable of solving the task required of the monkey, but how are just those neurons selected by control of the decision process from a population of many millions? Presumably, monkeys do not carry a perceptual representation of their own nervous systems, so that selection must be a consequence of learning from external stimuli. The problem of selection would be made conspicuous and susceptible to study if it proved that the link between neuronal activity and perceptual decision could be broken by changing the nature of the stimulus in trivial ways and seeing whether the cells and the monkey still agree. For example, the size or colour of the moving dots might be changed. If such alteration of the stimulus were found to make the performance of neurons collapse, without affecting the animal, we could infer that the decision process had switched to another neuron or set of neurons — but that would return us to the selection problem. How was that neuron or set of neurons selected?

The question of how a neuronal process is reinforced so that it comes to depend on a particular stimulus is familiar in studies of learning, but how the mechanism functions at the level of the neuron is still a matter of speculation. Early in the development of learning theory, such questions

occupied the attention of people such as Lashley in the United States, Konorski in Poland and, notably, Hebb in Canada, but in recent years, learning theory has become more distant from neurophysiology. This is a great pity, but the experiments of Newsome *et al.* and the recent investigations of the neural basis of conditioning in the cerebellum[7] may rekindle interest in the fundamental questions of the neuronal influences of learning.

One feature of the experiment may have contributed greatly to its success. The monkey indicated its response by moving its eyes in the direction of stimulus motion. This is a very natural or, in the terminology of learning theory, 'prepared' response, which may have eliminated the need for a complex decision process between stimulus and response. If we ask what the nature of the decision process might be between MT and eye movement, the answer could be "none". Workers on visual perception and on eye-movement control mechanisms can be likened to two gangs of workmen tunnelling through the nervous system from opposite ends. They will meet soon and, on the evidence so far, they will do so without having to remove obstacles labelled 'perceiving' or 'decision process'. Such simplicity may be peculiar to eye-movement control, or it may be because this is the only stimulus–response system in primates that we understand in such detail. □

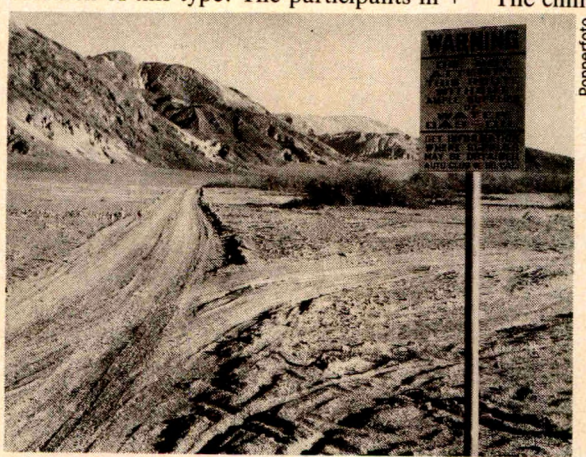
PALAEOCLIMATE

The desert shall rejoice



Wayne M. Wendland

MOJAVE Desert, which lies between Las Vegas and Los Angeles, and includes Death Valley, is the most arid region in North America. But sediments show that more than 8,000 years ago, this area was a massive lake. Detailed studies of the sediments, reported by Enzel and *et al.* elsewhere in this issue (*Nature* **341,** 44–47; 1989), show that the area supported lakes for prolonged periods about 3,600 and 400 years ago, as well. The obvious inference is that the changes indicate significant variations in climate during these periods.

To translate the kind of environmental information used by Enzel *et al.* into reconstructions of the palaeoclimate, it is necessary to find modern analogues that can be related to known weather patterns. Geological, geomorphic, archaeological and botanical evidence have all been used in this way. Although the conclusions from one such exercise can be equivocal, confidence clearly must grow in a climatic reconstruction if independent types of evidence indicate the same conclusion.

How reliable are such reconstructions? Apparently, they are quite good. The location of the main features of atmospheric circulation (the sub-tropical highs, sub-polar lows, jet streams and so on) have remained fairly constant throughout the Holocene (the past 10,000 years), as have their mean intensities and variance. This is not so surprising, as the main components forcing climate — Earth's orbit and the topography and distribution of land masses — have not changed significantly over this period. So modern analogues are reliable guides to the earlier climate, and together these indicate the variability of the Holocene weather.

The CLIMAP and COHMAP projects are prime examples of concerted efforts of research of this type. The participants in

Popperfoto

Aridity in Death Valley, Mojave Desert — a cause for caution.

CLIMAP (*Science* **191**, 1131–1144; 1976) gathered extant data on the concentration of plankton from deep-sea cores of the world's oceans to reconstruct sea-surface temperatures representative of Augusts 18,000 years ago, comparing variations with a modern relationship between plankton and sea-surface temperature. They found that sea-surface temperatures in the high latitude Atlantic and Pacific Oceans were depressed by as much as 4 °C relative to today. Along the west coast of South America and in the central Pacific near the equator, temperatures were up to 6 °C colder. Interestingly, all central oceans exhibited no change at about 20° S latitude.

In a somewhat different approach, a component of the COHMAP project involves reconstructing pollen assemblages for many locations based on general circulation characteristics for various times in the past 18,000 years (see T. Webb, P. J. Bartlein & J. E. Kutzbach in *North America and adjacent oceans during the last glaciation* (eds W. F. Ruddiman & H. E. Wright Jr) 447–462 (Geol. Soc. Am., Boulder, 1987)). The prehistoric general circulation is generated by a numerical circulation model whose boundary conditions are known sea levels and glacial extent for those times. The reconstructed pollen assemblages from the model match the extant record to a remarkable degree, thus verifying the method.

Enzel *et al.* link the existence of the perennial lakes they identify in the Mojave Desert to circulation patterns over the central and eastern Pacific Ocean. The modern analogues they use are eight episodes of increased rainfall since 1894 that led to the formation of ephemeral lakes, lasting 2–18 months, in the terminal basins of the Mojave River. The full climate record, including temperature, pressure, wind and humidity observations for the surface and upper air extends back only four decades, but the authors assume that it represents adequately the variance of the main features of the circulation pattern.

The climate of southern California and the San Bernadino Mountains is essentially mediterranean — warm and dry in summer, wettest in the winter. This is related to the seasonal migration of the polar jet stream, associated surface fronts off the Pacific and the Pacific sub-tropical anticyclone. Times of increased rainfall tend to be linked to an anomalous displacement to the south of these circulation features.

The mean sea-level pressure on the Californian coast tended to be strongly depressed during the wet episodes, and probably forced on-shore flow and moisture over southern California into Mojave. The inference is that similar sea-level pressure patterns persisted during the periods when perennial lakes were found in the Mojave. This is a significant addition to the data for this region and period, and the way it fits into the global pattern of inferred pressures will be fascinating to see. P 36,672 □

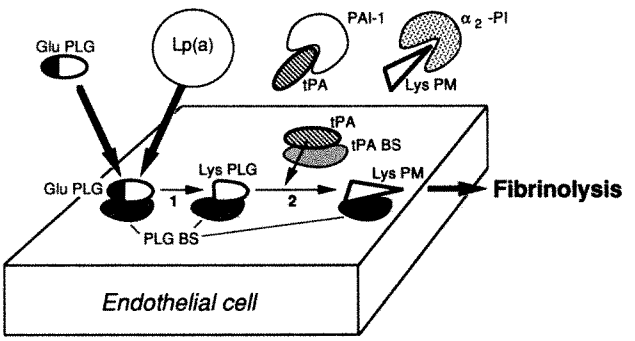
LIPOPROTEIN(*a*)

Thrombogenesis linked to atherogenesis at last?



James Scott

ARTERIAL thrombosis, the cause of heart attacks and strokes, is usually precipitated by rupture of an atherosclerotic plaque in a blood vessel. Despite this devastating and frequently fatal association, there has been no evidence linking thrombosis to the earlier process of plaque formation. A flurry of activity reported in several papers[1-8] and at two recent conferences* now shows that lipoprotein(*a*), a variant of low-density lipoprotein (LDL), the cholesterol-carrying augury of atherosclerosis, promotes coagulation and is an independent inherited risk factor for atherosclerosis.

Lipoprotein(*a*) (Lp(*a*)) consists of one (or two) molecules of apolipoprotein(*a*) (apo(*a*)), linked by a disulphide bridge to apo B-100 (refs 9, 10). It has several size isoforms, the amount of these in the circulation being strongly genetically determined[11,12] — high levels are a significant risk factor for atherosclerosis. Apo(*a*) is similar to plasminogen, from which the enzyme plasmin, that dissolves fibrin blood clots, is released by tissue plasminogen activator (tPA). Indeed, the human apo(*a*) and plasminogen genes are close together on chromosome 6 (ref. 13). The apo(*a*) molecule has 37 or more repeats of plasminogen 'kringle VI', the 36th of which contains the cysteine residue that forms the disulphide bridge to apo B-100. Both proteins are produced by the liver, and are probably linked by disulphide isomerase in the rough endoplasmic reticulum (ER). Apo B-100 is also a nucleus for lipoprotein assembly in the ER and Golgi apparatus of liver cells[14].

Various data[15] argue against Lp(*a*) having a serine protease function: rather, three recent studies suggest that it is a physiological inhibitor of plasminogen activation and so prevents unopposed plasmin generation[1-3] (see figure). Plasminogen-binding sites are widely distributed on peripheral blood cells and on vascular endothelial cells, and cultured endothelial cells also secrete and bind tPA. The proximity of the binding sites for plasminogen and tPA accelerates tPA-mediated plasmin generation, and surface binding shields plasmin and tPA from their inhibitors.

Lp(*a*) has now been shown[1-3] to compete with plasminogen for the plasminogen binding site with an equivalent affinity and capacity, but to have no effect on the fluid-phase activity of plasmin. The kringle domain is needed for plasminogen and Lp(*a*) binding. It has been estimated that at plasma concentrations of 30 mg dl^{-1}, Lp(*a*) reduces cellular plasminogen binding by 20 per cent, thereby suppressing endothelial cell fibrinolysis and producing a procoagulent state. In addition, there is a striking accumulation of Lp(*a*) on the endothelium of atherosclerotic coronary arteries, but not in normal blood vessels[2]. Plasminogen is readily detectable in normal vessels, but not in atherosclerotic vessels. These observations provide the most direct link so far between thrombogenesis and progressive atherosclerosis.

The endothelial cell fibrinolytic system. N-terminal Glu-plasminogen, Glu PLG; N-terminal Lys-plasminogen, Lys PLG; Lys-plasmin, Lys PM; plasminogen-binding site, PLG BS; tPA-binding site, tPA BS; α_2-plasmin inhibitor, α_2-PI; plasminogen activator inhibitor-1, PAI-1. 1, Conversion of Glu PLG to Lys PLG by surface-localized plasmin-like diisopropylfluorophosphate-sensitive serine protease. 2, Activation of plasminogen by tPA.

Further support for the aggressive role of Lp(*a*) in atherosclerosis comes from studies of plasma Lp(*a*) concentration and size isoforms in familial hypercholesterolaemia (FH), a condition caused by defects of the LDL receptor gene[4,5]. Individuals with FH show a threefold increase in plasma Lp(*a*) irrespective of their isoform phenotype, and those with the highest Lp(*a*) are at greatest risk of heart disease. The elevation of plasma Lp(*a*) is comparable to the two- to three-fold elevation in LDL cholesterol seen in FH, suggesting that defects of the LDL receptor could cause delayed catabolism of Lp(*a*) as well as of LDL. There is controversy about whether Lp(*a*) binds to the LDL receptor on cultured cells, as drugs that lower plasma LDL by increasing the number of LDL receptors do not affect plasma Lp(*a*) concentration, suggesting that Lp(*a*) is not cleared by the LDL receptor[4]. Perhaps the elevated Lp(*a*) in FH is due to increased synthesis, as seems to occur for LDL[16]. More probably, the excessive burden of LDL in the circulation in FH interferes with the normal clearance of Lp(*a*) by one or several possible clearance routes — the hepatic asialoglycoprotein receptor; the macrophage scavenger receptor, which converts the macrophage to an atherogenic foam cell; or the plasminogen-binding sites on circulating monocytes[1-3].

Two of the new reports[4,5] have significant implications for the management of FH and other forms of hypercholesterolaemia. It is important to ascertain whether individuals with hypercholesterolaemia and heart disease have the Lp(*a*) phenotypes normally associated with high circulating concentrations and whether reduction of both Lp(*a*) and LDL is needed to prevent atherosclerosis. That the latter is the case is suggested by earlier studies showing that people with normal cholesterol but with Lp(*a*) higher than 30 mg dl^{-1} have double the risk of heart disease[10].

The concentration of Lp(*a*) in the circulation varies from almost undetectable to more than 100 mg dl^{-1} (ref. 10). The size of apo(*a*) ranges between 450,000 and 750,000 daltons, and in humans there is an inverse relationship between the size of apo(*a*) and the level of Lp(*a*)[11,12]. The variation in size of Lp(*a*) could result from variation in the number of kringle repeats[9]. Three recent studies[6-8] on Lp(*a*) in monkeys have helped to clarify these issues. The size of plasma apo(*a*) in the circulation correlates closely with apo(*a*) messenger RNA size — size isoforms are inherited as independent alleles, suggesting that in monkeys variation in kringle number encoded by the gene determines Lp(*a*) size. Lp(*a*) concentrations and phenotypes co-segregate, and more than one concentration can be associated with a single size isoform. The amount of Lp(*a*) in plasma corresponds to apo(*a*) mRNA concentrations, suggesting that the Lp(*a*) level is established by transcription rate. Thus apo(*a*) size and concentration alleles are found at the apo(*a*) structural locus and seem to depend on different properties of the gene. Discrepancies between mRNA and plasma levels suggest that post-transcriptional mechanisms are also operative. For example, a null allele produces significant levels of mRNA, but only traces of Lp(*a*) are detectable in the circulation.

Lp(*a*) plasma concentrations in humans are also influenced by metabolic factors. Thus Lp(*a*) is increased in diabetes mellitus and nephrotic syndrome; decreased by dietary fish oil and by combined nicotinic acid and neomycin treatment, but little affected by diet[6,10] (I. Karadi, Semmelweis

* International Atherosclerosis Congress, Vienna, 20–22 April 1989; *From Phenotype to Gene in Common Disorders*, Oslo, 18–20 May 1989.

University; K. Berg, University of Oslo; G. Dahlen, University of Umeå). Most of these situations influence plasma apo B levels in the same direction, and act in part by affecting lipoprotein biosynthesis in the liver[8,14,17–21]. Taken together, the evidence suggests that the metabolic regulation of Lp(*a*) production is linked to that of apo B-100 once they have been covalently bonded in the endoplasmic reticulum. If this is so, how can the lack of correlation between LDL and apo B and Lp(*a*) levels be explained[10]? That LDL and Lp(*a*) are cleared by different routes and that excess apo B-100 is always available in the ER for linking with apo(*a*) suggests an answer. It is also possible that Lp(*a*) metabolism follows a different intracellular pathway from that of other liver lipoproteins. More probably, the fate of apo B-100-containing lipoproteins in the secretory pathways will determine the fate of Lp(*a*). The production of apo B-100 containing lipoprotein particles is regulated by post-translational mechanisms — partly by sorting between intracellular protein degradation and secretion[14] □

LOW-MASS STARS

Protostars in from the cold

A. P. Whitworth

Until recently, little was known about the origin of low-mass stars (those whose mass is no more than 2 solar masses). With a few notable exceptions, astronomers had tended to concentrate on high-mass stars, seduced by the spectacular emission nebulosity that follows the birth of a high-mass star, but which reveals little about its conception or gestation Following a recent meeting*, it is clear that this bias has been more than redressed. The observational picture of how low-mass stars form is now extremely detailed and is rapidly being translated into a much better theoretical understanding of the processes involved. By contrast, high-mass stars still remain something of a mystery.

There are two reasons for this turnabout. The first is the opening up of new windows in the electromagnetic spectrum. Throughout the late 1960s and well into the 1970s, optical and radio astronomy held sway Observations were focused on and around H II regions (bright emission nebulae surrounding young hot stars). Although this inevitably selected sites of high-mass star formation, it was widely presumed that low-mass stars formed in the same places. With the rapid development of infrared and sub-millimetre observing techniques in the last decade, it has become possible to study the more quiescent regions of star-forming cloud complexes The result has been to bring into focus regions like the Taurus–Auriga cloud complex where only low-mass stars are forming.

The second reason has more to do with theoretical necessity. It seems inescapable that the circumstances producing the globular clusters in the halo of our Galaxy differ fundamentally from those responsible for the OB associations (small, unbound groups of young, massive stars) in the galactic disk. It would be extraordinary if all star formation followed a single pattern and that variations were due solely to statistical fluctuations. Yet, until recently, this is essentially what astrophysicists were obliged to assume, there being no hint of which circumstances exerted which influence on the course of star formation. To have assumed that the efficiency of star formation or the initial mass function depended in some systematic way on epoch or environment would have been blind speculation.

It is now known that low-mass stars form more or less continuously, but very slowly, throughout the volume of cold, quiescent, dark clouds like Taurus–Auriga as these clouds cruise round the galactic disk (J. Bally, AT&T Bell Laboratories) High-mass stars tend to form only in the most dense parts of larger, hotter and more turbulent clouds; their formation is concentrated in the spiral arm regions of the galactic disk and seems to be triggered by compression, presumably in a galactic shock.

Quiescent regions of low-mass star formation tend to possess an ordered large-scale magnetic field structure (K Strom, University of Massachusetts), as revealed by polarization and Zeeman measurements. Because the rotation axes of young stellar objects in these regions are well aligned both with one another and with this background field, we conclude that the magnetic field plays a dominant role in the formation of low-mass stars.

The most plausible interpretation of this observation is that, although the condensation of low-mass stars is driven by their self-gravity, it is tightly controlled by the entrained magnetic field (S. Lizano, University of Florence). The magnetic field slows down the early stages of condensation because the neutral particles (which constitute most of the matter) experience a friction force as they slip past the charged particles (which are tied to the magnetic field lines by the Lorentz force). The resulting quasistatic condensation takes 10^6–10^7 years and results in the formation of dense, centrally concentrated cores with properties similar to those observed in Taurus — having protostellar masses about that of the Sun and radii about 10^{15} m.

The entrained magnetic field also exerts the torque that reduces the angular momentum of a condensing protostar, thereby enabling it to reach stellar densities without spinning so fast that it breaks up. This has the effect of aligning the spin axis of a condensing protostar with the background magnetic field and hence with the spin axes of other protostars in distant parts of the cloud, as described by Strom.

The spin axes of low-mass protostars can be identified with some precision. Often, observations indicate the presence of a disk around the protostar, presumably an accretion disk in which gas and dust spiral inwards and onto the rotational equator of the protostar. And in many cases matter is being blown out in a supersonic jet along the two poles of the rotation axis, boring a hole through the surrounding interstellar medium, and pushing ahead great blobs of molecular gas The resulting system of shock waves produces chains of Herbig–Haro objects sometimes terminating in a clearly defined bow shock (see also the recent News and Views article by Hartmann in *Nature* **340**, 432; 1989).

Modelling of protostellar accretion disks is still elementary, but typically they have radii of about 5×10^{14} m and masses of 0.1–1.0 solar masses. Most of the uncertainty in the mass derives from our poor knowledge of the far-infrared emissivity of protostellar dust (J Emerson, Queen Mary College, London).

* *Low-Mass Star Formation and Pre-Main Sequence Objects*, ESO Workshop, 11–13 July 1989, Munich

Ultimately, some (and maybe all) protostellar disks will presumably develop into planetary systems. From general considerations it can be shown (G. Morfill, Max-Planck-Institut, Munich) that the variations in radial temperature and surface density that were required to produce the different masses, elemental compositions and formation timescales of the planets in the Solar System arise naturally in protostellar disks.

But fundamental problems remain. We are still very far from understanding why most stars are in binary and multiple systems. There are compelling theoretical reasons to believe that binary formation is a highly non-quasistatic process (J. Pringle, Cambridge University). If this reasoning is correct, then it is very difficult to see how the quiescent, centrally condensed protostellar cores modelled by Lizano can become binaries and we are forced to look to some other site for binary formation. □

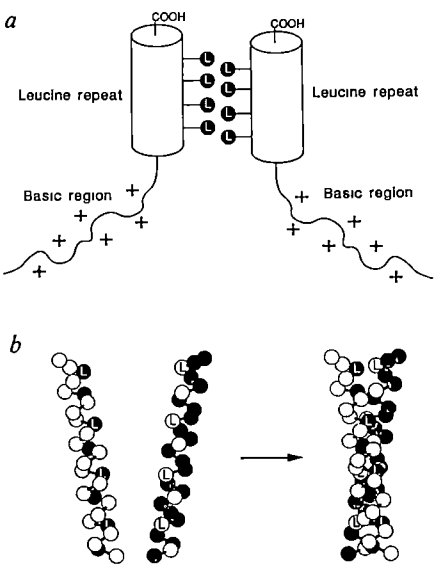
GENE REGULATION

Action of leucine zippers

Ted Abel and Tom Maniatis

A FUNDAMENTAL question in gene regulation is how a finite number of regulatory factors and DNA-binding sites can generate the enormously complex pattern of tissue-specific gene expression required for development. Steve McKnight and colleagues provided a new way of thinking about this problem last year when they discovered[1] the 'leucine zipper' — a stretch of 35 amino acids containing 4–5 leucine residues separated from each other by 6 amino acids — in various DNA-binding proteins. They proposed[1] that the leucines are arranged on one side of an amphipathic α-helix and that the leucines on two such helices would interdigitate leading to dimerization. Noting that the zipper was immediately preceded by a region rich in positively charged amino acids, they further suggested that dimerization would arrange the basic regions of the two sub-units in a configuration that allows specific interactions with a DNA-recognition sequence (see figure), a model that was soon confirmed in many laboratories. The 'domain swap' experiments reported recently by Kouzarides and Ziff[2] and by Sellers and Struhl on page 74 of this issue[3] have particularly interesting implications for combinatorial models of gene regulation.



The leucine zipper was originally identified in a site-specific DNA-binding protein known as C/EBP. A computer search[1] revealed a similar repeat in the amino-acid squences of Fos, Jun and Myc, nuclear proteins encoded by proto-oncogenes, and in the yeast transcription factor GCN4. Meanwhile, evidence was accumulating for a role of the *fos*-gene product in the control of gene expression during adipocyte differentiation, and a Fos-related protein was identified as the product of the c-*jun* oncogene (reviewed in refs 4,5). Also, the c-Jun protein was shown to be a member of the AP-1 family of transcription factors. A series of experiments subsequently demonstrated that the Fos and Jun proteins form a heterodimer that binds to the AP-1 or TRE (TPA-responsive element) regulatory sequence in certain genes and activates transcription. The Fos–Jun heterodimer binds the TRE with high affinity, and is a strong transcriptional activator; the Jun homodimer binds more weakly and is less potent. The Fos protein alone does not dimerize or bind DNA. GCN4 binds to a yeast regulatory sequence that is identical to TRE, but it does so as a homodimer.

As suggested by the leucine-zipper model, both C/EBP (ref. 6) and GCN4 (ref. 7) dimerize and recognize palindromic sequences. Direct evidence that the zipper creates a dimerization interface between protein subunits was provided by structural studies of a synthetic peptide corresponding to the leucine-zipper region of GCN4 (ref. 8). Circular dichroism and two-dimensional NMR studies revealed that these peptides associate to form very stable dimers of α-helices. McKnight and colleagues originally proposed that these helices would associate in an antiparallel fashion, which would allow the long leucine sidechains to interdigitate "like the teeth of a zipper". Cross-linking studies[8], however, demonstrated that the helices of the leucine zipper region of GCN4 are parallel in the dimer, a conclusion supported by analyses of the effects of specific leucine substitutions on dimerization of C/EBP (ref. 6), Fos and Jun[9].

The leucine zipper of GCN4, therefore, seems to have the characteristics of a coiled coil, found in many fibrous proteins such as keratins, lamins and myosin[10]. The structure of such coils, originally proposed by Francis Crick[11], is a left-handed twisting of two α-helices about each other (*b* in the figure). Classically, the physical basis of this quaternary structure is provided by a 4–3 repeat of hydrophobic amino acids that lie along the face of the α-helix. Efficient 'knobs-into-holes' packing of these apolar side chains occurs at the interface between the two helices. The heptad repeat of hydrophobic amino acids interspersed within the leucine repeats of GCN4, Jun and C/EBP could give the same coiling. It appears, therefore, that the leucine sidechains may not interdigitate, but rather they interact with the alternate, non-leucine, hydrophobic residues in the opposing helix[8].

The leucine zipper regions of Myc and Fos, however, do not contain hydrophobic residues at most of the alternate positions. The ability of Fos to dimerize with Jun could, therefore, be a consequence of different types of interactions at the helix interface. For example, the methylene groups of a lysine side chain at one of these positions provide an alternative hydrophobic contact. Electrostatic effects could also act to stabilize heterodimers of Fos and Jun[12]. The role of these novel interactions in determining the specificity of cross-dimerization remains to be established.

Other transcriptional regulatory proteins, such as the *Drosophila* zeste protein and the lymphoid cell-specific octamer-binding protein (OTF-2), have potential

Diagrams showing structural features of the leucine-zipper motif present in several DNA-binding proteins. *a*, The bipartite DNA-binding domain of C/EBP (ref. 1). The leucine repeat region, which could form an eight-turn α-helix (drawn as a cylinder), serves as a dimerization interface. Dimerization is necessary for specific interactions between the adjacent basic regions and the DNA-recognition sequence. *b*, The coiled-coil model for the structure of leucine zipper[8] (modified from ref. 24). The α-helical regions of two monomers are illustrated on the left; each residue is represented by a sphere centred on the C^{α} atom. In the dimer (right), these helices form a coiled coil, a structure in which two parallel helices are intertwined. The leucine residues are indicated by black or white balls marked with an L, and the alternating hydrophobic repeat (present in many, but not all, leucine zippers) by plain black or white balls. These two interspersed heptad repeats, known as the 4–3 repeat, form the interaction surface between the two helices.

leucine-zipper domains, but they are not required for binding to known DNA-recognition sequences[13]. These domains could be required for interactions with other proteins or with DNA-recognition sequences not yet identified. The leucine zipper has also been identified in certain types of membrane proteins, including a family of voltage-gated potassium channels[14], glucose-transporter proteins[15] and the F glycoproteins of paramyxoviruses[16]. In each case, however, the zipper is not adjacent to a basic region, so that the leucine repeat may be an independent structural domain used by diverse families of proteins for specific protein–protein interactions.

The combination of a basic domain and a leucine zipper in Fos, Jun, GCN4 and C/EBP indicates that they represent a novel class of DNA-binding proteins. Recent mutagenesis experiments have precisely defined the dimerization and DNA-binding motifs of proteins in this family. When leucine residues in the zipper region are altered, even to other hydrophobic amino acids, the proteins neither dimerize nor bind DNA[5,6,9,17,18]. By contrast, mutations in the basic region prevent DNA binding, but do not interfere with dimerization[5,6,9,17]. These observations strongly support the notion of separate dimerization and DNA-binding domains originally proposed by McKnight and colleagues[1].

The new domain-swap experiments of Kouzarides and Ziff[2] and Sellers and Struhl[3] further explain the independent functions of these domains. By placing the Fos basic region next to the zipper of GCN4, both groups show that the basic region of Fos can specifically bind to the TRE if present as a dimer. Although the native Fos protein cannot form a homodimer and binds DNA only by forming a Fos–Jun heterodimer, the Fos/GCN4 chimaeric protein forms a homodimer that interacts specifically with the TRE. The basic regions of Fos, Jun and GCN4, therefore, are equivalent in their DNA-binding abilities, indicating that their differential affinity for the TRE results from the differing ability of their leucine zippers to form dimers.

Leucine-zipper proteins do not dimerize randomly: GCN4 and C/EBP form homodimers, whereas Fos and Jun participate in heterodimeric complexes. Kim and co-workers have recently shown[12] that short peptides containing the leucine-zipper regions of Fos and Jun preferentially form heterodimers of parallel α-helices. Kouzarides and Ziff investigated[2] the basis for selective dimer formation by fusing the Fos zipper to the GCN4 basic region. Unlike GCN4 itself, this chimaeric peptide forms a complex with Jun, and the heterodimer binds specifically to the TRE, indicating that the leucine-zipper regions of Fos, Jun and GCN4 are both necessary and sufficient to determine the selectivity of dimer formation. The structural basis for this selectivity is not yet understood. But because all zipper proteins contain the leucine repeat, other amino acids in this region must play an essential role. Substitution of single non-leucine residues has no effect on dimerization, but this may indicate that multiple interactions along the faces of the helices contribute to the stability of the dimer[17,18]. A systematic series of regional swaps or multiple amino-acid substitutions will be required to identify the molecular basis of the specificity.

All heterodimers formed between the leucine-zipper proteins studied so far, bind to the same DNA sequence. But heterodimer formation could result in novel DNA-recognition properties, or in different regulatory activities, thus expanding the repertoire of a finite number of transcriptional activator proteins. The demonstration that a heterodimeric repressor protein can bind to a hybrid operator sequence[19] is a precedent for the notion that a heterodimer can bind to a sequence not recognized by either homodimer. The basic regions of Fos, Jun and GCN4 recognize the same DNA sequence, but C/EBP recognizes an entirely different sequence. It would be interesting to determine whether the juxtaposition of two different basic regions in a heterodimer of C/EBP and Fos could generate a novel DNA-binding specificity. The possibility that different protein complexes display distinct transcriptional regulatory activities is indicated by the observation that Fos can act as a positive or negative regulatory protein in different DNA-sequence contexts. Fos, for example, seems to stimulate transcription when bound to the TRE, but acts as a negative factor when bound to an adipocyte-specific regulatory element[4,5]. Fos also negatively regulates its own expression[4,5].

The formation of heterodimers may also be important in the function of an entirely different set of transcriptional activator proteins, the Myc/MyoD or helix-loop-helix family[20]. These proteins interact to generate complexes that bind a specific DNA sequence with a higher affinity than the individual protein subunits[21]. E47 and E12, for example, are proteins that bind to the immunoglobulin-κ-chain enhancer as dimers; MyoD is a transcriptional activator that converts fibroblasts to myoblasts, and which seems to act by turning on muscle-specific gene expression. These proteins form heterodimers that bind to nearly identical sequences present in both the immunoglobulin and muscle-creatine-kinase enhancers[21]. The formation of heterodimers in this case requires a novel dimerization motif within the helix-loop-helix motif[21]. Interestingly, at least two members of the Myc/MyoD family, E12 (ref. 20) and myogenin[22], also contain a leucine repeat. Thus, interfamily dimerization may be possible.

Pairwise association of proteins through two distinct sets of dimerization domains could also lead to the formation of a virtually unlimited variety of multicomponent complexes. Members of the helix-loop-helix family of proteins include tissue-specific factors such as MyoD and two other myogenic regulatory proteins, as well as *Drosophila* genes that are involved in neurogenesis, such as *achaete-scute* and *daughterless*[20]. Other members of this family, such as E47, however, are expressed in all cell types, indicating that tissue-specific gene expression could be the result of novel combinations of heterodimers.

The finding that leucine zippers are responsible for specific heterodimer formation provides a conceptual framework for understanding combinatorial models of gene regulation. Transcriptional regulatory proteins consist of DNA-binding and transcriptional activation domains which are interchangeable between individual proteins as well as among widely divergent organisms[23]. However, the complexity involved in achieving the highly specific pattern of gene activation required for the growth and development of eukaryotic organisms is staggering. This specificity may be achieved, at least in part, by novel protein–protein interactions made possible by the dimerization of regulatory proteins. □

PLASMA PHYSICS

Surfing for light waves

A. R. Bell

THE diversity of nonlinear interactions involving waves in plasmas is both a fascination and a frustration to plasma physicists. Often the interactions arise unexpectedly to frustrate attempts to design useful plasma devices, but the very wealth of interactions gives great scope for inventive ideas. The latest ingenious idea springs from the University of California at Los Angeles where S. C. Wilks, J. M. Dawson and co-workers have recently suggested that it may be possible to 'accelerate' photons in a plasma (*Phys. Rev. Lett.* **62**, 2600–2603; 1989). By this they mean that photons initially with low energy can be changed into high-energy photons as they pass through a suitably excited plasma.

Schematic of the photon accelerator, showing the electron plasma wave, with the wavefront moving close to the speed of light and boosting the frequency of the light pulse.

Behind the concept is the hope of producing a high-frequency, coherent electromagnetic wave by upshifting a low-frequency coherent wave — an alternative to direct laser action at the higher frequency. The idea presents an enticing prospect. Coherent high-energy radiation is not easily produced, especially when X-ray energies are approached. The proposed scheme is similar to those currently being investigated for accelerating charged particles — for example the plasma beat-wave accelerator (PBWA). Indeed, Dawson was, with T. Tajima, one of the originators of the beat-wave and related ideas (*Phys. Rev. Lett.* **43**, 267–270; 1979).

In either scheme, a large-amplitude wave is generated in an ionized plasma by intense laser beams or by an energetic particle beam. The wave consists of a sinusoidal variation in electron density which moves with a phase velocity slightly less than the speed of light

For simplicity, view the process in the reference frame moving with the plasma wave. In this frame the sinusoidal density variation is stationary. In the photon accelerator, a short pulse of electromagnetic radiation (short compared with the wavelength of the plasma wave) can be trapped in one of the low-density troughs of the wave, because electromagnetic radiation of a given frequency cannot propagate above a certain density (the critical density). The density trough can be seen as behaving like a potential well for the photons comprising the electromagnetic pulse. The group velocity of an electromagnetic wave propagating up a density ramp reduces as the density increases, until it becomes zero at the critical density where it is reflected down the density gradient. A pulse initially placed at the bottom of the trough and travelling backwards with respect to the wave will climb the wall of the trough, reverse its direction when it reaches the critical density and returns to its original position with its original frequency and energy. Its group velocity is unchanged in magnitude but reversed in direction

Transforming back into the laboratory frame, we see that because of the change of direction, the magnitude of the laboratory group velocity has in fact increased: the pulse starts at the bottom of the trough, moving in the same direction as the plasma wave but at a slightly lower velocity (a suitable choice of light frequency gives the required group velocity). The pulse initially drops back relative to the wave, but then accelerates to a velocity higher than that of the plasma wave, eventually returning to the bottom of the trough with an increased group velocity Because the group velocity has increased, so have its frequency and photon energy — the photons have been accelerated.

The analysis by Wilks *et al.* shows that the basic scheme can increase the electromagnetic frequency by a factor of around 5, although this requires a plasma wave in which the excursion of the electon density from its mean is half the mean density. This amplitude is much larger than that of any coherent plasma wave created so far by proponents of the PBWA, but it is not impossible given the rapid developments in this field. To obtain a larger frequency upshift or to manage with less extreme plasma waves, Wilks *et al.* suggest steadily raising the plasma density along the length of the accelerator.

Many problems still need to be addressed. For example, a suitable means of driving a plasma wave with the required amplitude, coherence and phase velocity needs further investigation. The ultimate efficiency of the system is uncertain Undesirable wave–wave interactions could compete with those desired for photon acceleration. And problems could arise when the present one-dimensional analysis is replaced by a full two- or three-dimensional one. The proof of the theoretical pudding will be in the experimental realization. □

DAEDALUS

Bubbling upwards

LAST week Daedalus invented a solution for blowing really robust soap bubbles. It contains big closed-loop polymer molecules: any small puncture is certain to be surrounded by at least one loop molecule. So it cannot spread and is soon healed by brownian motion. Invulnerable to the usual mode of failure, a 'Hyberbubble' is a wonderfully light and robust structure, rich with technological promise.

Daedalus is directing this promise firmly upwards. He points out that a traditional balloon is only partly filled with gas before its release. As long as its envelope is slack, the pressure inside and outside are equal and the lift of the balloon remains constant. But as it rises through the thinning air, it expands steadily and ultimately fills taut. The balloon has reached its ceiling: any further ascent reduces its lift.

But a Hyperbubble would behave quite differently. Such a stable soap bubble would simply expand indefinitely as it rose and would pull taut only when it had thinned to a perfect monolayer. Daedalus calculates that a hydrogen-filled Hyperbubble with an initial radius of a mere metre or so, and an initial film thickness of 0.1 mm, could lift itself from sea level and reach about 160 km altitude. In practice, of course, the bubble would have the usual 0.001 mm soap-film thickness even at ground level, but could carry the extra liquid in a reservoir to top-up the thinning film as it expanded at higher altitudes.

Attaching a payload to a big liquid-skinned balloon poses intriguing problems. Daedalus hopes that a complex corded harness, light and fairly flexible, can be given such an extended line of wetted contact with the bubble that the total surface tension along the line will support a few kilograms of instruments. A space-going Hyperbubble cannot contain water, which would evaporate rapidly in the low pressure. Liquid polymers, high-molecular-weight detergents and other novel soap-film components are being investigated. But ultimately Hyperbubbles should lift research equipment up to 100–200 km amazingly simple, cheaply and reliably.

At operating altitude a Hyperbubble will be a vast attenuated object drifting before whatever vacuous molecular wind there is up there. Though immune to punctures from micrometerorites, it will still slowly lose gas by diffusion, and gradually descend. In the process it will slowly shrink and thicken, at each stage forming an effective parachute for the local atmospheric density. Cosmic-ray film packs, survey cameras, magenetometers, all will be lifted gently and cheaply into near space and as gently returned. The robustness and reliability of a Hyperbubble would only really be overwhelmed by collision with an orbiting satellite.

David Jones

Vent fauna on whale remains

SIR—Concentrations of animals supported at least partially by chemoautotrophic production are known from a variety of geologically produced reducing environments at the deep-sea floor[1-6]. During DSRV *Alvin* dive number 1,949 (10 November 1987) in the 1,240-m deep Santa Catalina Basin (33°14'N, 118°30'W) we discovered a chemosynthetic community fuelled by a novel source of reduced compounds — the intact skeleton of a 20-m long whale. Data collected during subsequent dives (numbers 2,132–2,138, 5–11 November 1988) indicate that the partially buried remains of this blue or fin whale have produced a microhabitat distinct from the surrounding, well studied[7-9] basin floor.

Many of the larger whale bones and nearby patches of sediment were covered with white microbial mats reminiscent of those at some hydrothermal vents[10,11] and petroleum seeps[2]. The mats were composed of a diverse assemblage of colourless sulphur bacteria, including large filaments (100 μm wide × 2–3 cm long) most closely related to *Beggiatoa gigantea*[12]. Recovered whale bones were laden with oil and smelled strongly of sulphide, and the pore water of underlying surface sediments had sulphide concentrations of up to about 20 μM (measured by B. Hales with sulphide electrodes on recovered cores), indicating that the chemical reducing power supporting these bacterial mats is derived from bone-oil seepage. In dozens of previous submersible dives and camera surveys at the Santa Catalina Basin floor[7-9], we had never before observed *Beggiatoa* mats.

The whale skeleton also harboured six metazoan species not encountered before in the Santa Catalina Basin (see table). Among these were two species of large vesicomyid clams, *Vesicomya gigas* and *Calyptogena* cf. *pacifica*, which nestled in bone crevices and dotted sediments near the whale. We observed more than 50 living individuals and hundreds of shells, ranging from 2 to 10 cm in length. Scoop net samples suggested that most of these clams live hidden in the sediment near the skeleton.

Other atypical basin species included the mussel *Idasola washingtonia*, an undescribed cocculinid limpet and the snail *Mitrella permodesta*; all three were abundant on exposed bone surfaces with densities of >100 m^{-2}. We also collected the bivalve *Lucinoma annulata* from small cavities in the skeleton, and from adjacent sediments.

Several of these species are characteristic of reducing habitats in the deep north-east Pacific (see table). *Vesicomya gigas*, (misidentified in refs 13 and 14 as *Calyptogena pacifica*; R. D. Turner, personal communication) occurs in abundance at Guaymas Basin and Juan de Fuca vent fields (ref. 13 and R. D. Turner, personal communication), and hosts large populations of endosymbiotic chemoautotrophic sulphur bacteria (based on transmission electron microscopy and enzyme assays; J.W.D. *et al.*, manuscript in preparation). *Calyptogena pacifica* contains similar endosymbionts and occurs at many sites, including vents and a cold seep[15-17]. *Lucinoma annulata* also obtains nutrition from chemoautotrophic endosymbionts[15], and occurs in abundance near sewage outfalls off California[18]. Members of this genus are also found in petroleum-seep communities of the deep Gulf of Mexico[14]. Finally, *M. permodesta* abounds in anoxic sediments in some Californian basins (J. McLean, personal communication), and *I. washingtonia* has been collected at the Guaymas vents (R.D. Turner, personal communication), possibly at Juan de Fuca vents (V. Tunnicliffe, personal communication), and widely on sunken wood[19] Transmission electron micrographs and enzyme assays indicate that *I. washingtonia*, but not *M. permodesta*, hosts chemoautotrophic bacteria (J.W.D. *et al.*, manuscript in preparation).

The occurrence of a chemosynthetic community on the whale bones appears not to be an isolated incident; endosymbiont-containing *I. washingtonia*, as well as *M. permodesta* and pyropeltid limpets (a family known previously only from vents[20]), have recently been found on whale bones trawled from three other slope sites off California (W. Wakefield, personal communication).

In retrospect, it is not surprising that a whale carcass on the energy-poor deep-sea floor should produce a community with ecological and taxonomic similarities to other deep-sea reducing habitats. Microbial degradation of organic-rich whale remains appears certain to yield sulphide from sulphate reduction[21] and putrefaction[22]. The consequent occurrence of sulphides with a nearby source of oxygen (in bottom water) should provide a habitat analogous to seeps and vents in its suitability for sulphide-oxidizing bacteria and their metazoan hosts[13,15].

These findings suggest that whale skeletons might serve as important 'stepping stones' for the dispersal of deep-sea ▶

TABLE 1 Distribution of animal species associated with the whale skeleton not normally found in the Santa Catalina Basin

Species	Vent/seep collection sites	Other collection sites	
		Locality	Habitat type
*Vesicomya gigas**	Guaymas Basin, Juan de Fuca Ridge	Gulf of California	vents?
*Calyptogena pacifica**	San Diego Trough fault, Guaymas Basin? Northern California, Juan de Fuca Ridge?	Alaska slope	?
*Lucinoma annulata**	—	California Basins	anoxic sediment
*Idasola washingtonia**	Guaymas Basin, Juan de Fuca Ridge?	Washington slope	?
		Southern Japan slope	sunken wood
		New Zealand slope	sunken wood
		Central California slope	whale bones
Mitrella permodesta	—	California Basins	anoxic sediment
Cocculinid limpet	—	—	—

* Known to contain chemoautotrophic endosymbiotic bacteria

animals that depend on chemosynthesis. For that to be the case, they must at least provide reductants for long enough to allow chemosynthesis-dependent species to reproduce — more than five years for many vent species[13]— and be common in space relative to other reducing habitats.

If the large (up to 10 cm) vesicomyids on and around the whale bones grow at the high rates measured for hydrothermal-vent vesicomyids[13], the reducing habitat must have been present for at least 3–17 years. Assuming, conservatively, that whale skeletons support chemosynthesis for five years in the deep sea, and that only half of the approximately 1,000 adult grey whales (*Eschrichtius robustus*) that die each year in an 8×10^5-km^2 area of the north Pacific[23] sink to, and remain on, the sea floor (also a conservative estimate; D W. Rice and D. Withrow, personal communication), there would be approximately one reductant-rich skeleton per 300 km^2. If these carcasses were randomly distributed over the grey whale range, the average distance between nearest neighbours would be about 9 km (ref. 24). In fact, deaths and sinking carcasses seem highest along migration routes between Alaskan waters and the Gulf of California[24,25]. These rough but probably conservative calculations suggest that whale skeletons may indeed provide persistent and abundant stepping stones for dispersal of deep-sea chemosynthetic communities over large areas of the north-east Pacific.

Greenhouse dust

SIR—Recent concern expressed by the scientific community and by ecologists over anthropogenic 'greenhouse gases', notably CO_2, has been attended by a neglect of other factors that contribute to a fluctuating background level of atmospheric (surface) temperature[1]. It is well known that the mean surface temperature can fall by amounts ranging from a few tenths of a degree to a degree or more in extreme cases immediately following a major volcanic eruption, and that the effect can persist for a year or two[2,3] For example, the Tambora eruption of 1815 led to the 'year without summer' and smaller effects are clearly observed in more recent volcanic events, including the Mount St Helens eruptions of 1980. Whether the surface temperature falls or rises following an injection of volcanic particles, and by how much, is a complex issue depending on, among other factors, the particle size distribution and bulk optical properties[4].

Another important background effect could result from the accumulation at the Earth of extraterrestrial dust particles — interplanetary dust including Brownlee particles (a subset of interplanetary dust particles sampled in the Earth's upper atmosphere) and particles arising from direct encounters with small icy comets These particle inputs are all highly variable as well as uncertain. The calculations that follow are therefore illustrative, but not definitive The Brownlee-particle influx, estimated from direct collections of $\sim$ 10-μm-sized particle clusters, may be $\sim 10^{10}$ g yr^{-1} (using data in ref. 5), but a submicron component, which is expected to be present, could result in a higher total flux $\sim 10^{11}$ g yr^{-1} With an estimated stratospheric residence time of $\sim$ 10 yr for the smallest grains we could reasonably expect an average load of $\sim 10^{12}$ g of extraterrestrial particulate material, giving a surface density of $\sim 2 \times 10^{-7}$g cm^{-2} over the entire Earth.

For the highly porous silicate or organic particles of radii $\sim 10^{-5}$ cm expected from comets and micrometeorites, a typical mass extinction coefficient as a result of scattering at visible wavelengths is of the general order of 10^5 cm^2 g^{-1} (ref. 6). This is about 10–100 times the value of the mass absorption coefficient for silicates or organic solids at their infrared absorption peak near the wavelength of $\sim$ 10 μm. For a surface density $\sim 2 \times 10^{-7}$ g cm^{-2} of such particles, which are effectively 50 per cent backscatterers, an effective optical depth for attenuation of visible sunlight available for heating the surface is $\sim 0.5 \times 10^5 \times 2 \times 10^{-7} \simeq 0.01$, whereas their contribution to heating through infrared absorption will be negligible.

In view of the highly variable nature of the extraterrestrial particle load a typical fluctuation of this effective optical depth will also be of the same order, $\Delta\tau \approx 0.01$. The solar input for heating could thus fluctuate by $\Delta F/F \approx 1-e^{-0.01} \approx 0.01$, which corresponds to a temperature fluctuation $\Delta T/T \approx \Delta F/4F \approx 0.25$ per cent. Because temperature fluctuations of about this magnitude are being discussed in connection with the greenhouse problem, we suggest that a proper assessment of the matter must include a consideration of processes of the type discussed above. Small decreases in the background load of extraterrestrial dust would give rise to apparent increases in global temperature. Large increases of this load, which would occur on rare encounters with large comets, could lead to ecodisasters[7,8].

Cold fusion and brown dwarfs

SIR—Jones *et al* [1] claim to have observed neutrons resulting from cold nuclear fusion of deuterons within the palladium metal lattice. They state that observation of naturally occurring ^{3}He in the Earth (again attributed to cold p–d fusion occurring in geophysical environment at a rate of $\sim 10^{-24}$ fusions per d atom per second) and the excess luminosity radiated by Jupiter suggested to them new directions for laboratory studies of cold nuclear fusion.

For instance, the 10^{18}W radiated by Jupiter could be produced by p–d fusions at a rate $\lambda_f \approx 10^{-19}$ fusions d^{-1}s^{-1}. Recently, objects intermediate in mass between Jupiter and a typical star, brown dwarfs, have also been attracting attention; some may have been detected[2]. An object about 20 times the mass of Jupiter ($20M_J$) would have a central density ϱ_c (which for such objects, with near degeneracy at their cores, scales as M^2) about 400 times larger. An object of $30M_J$ would have $\varrho_c \sim 900$ times larger, and so on. Their central pressure scales as $M^{10/3}$ and would then be much larger than that of Jupiter. So, for a similar p–d composition (which one can reasonably assume for unevolved stellar objects), such objects would have a cold fusion rate ϱ_c^2–times larger (the product of number densities of p and d) than Jupiter. A $20M_J$ brown dwarf undergoing p–d cold fusion would radiate $\sim 1.6 \times 10^{22}$ W or nearly 10^{-4} of the solar luminosity. But from their extreme faintness such objects are deduced to emit only 10^{-7} solar luminosity or less (even for an estimated $50M_J$ object which should be much brighter, with 6×10^{-13} fusions d^{-1}s^{-1}). One can reasonably conclude that Jupiter is not getting its luminosity from such reactions which should have made brown dwarfs appear several magnitudes brighter.

- Image enhancement/reinforcing
- Image storage and reconstruction

PROTOCOLS IN ELECTRON MICROSCOPY

PRINCIPAL EDITORS

Prof. A.W. Robards, Institute for Applied Biology, York, UK and **Dr. A.J. Wilson,** CCTR, York, UK

With every Protocol you get ...

Step-by-step description of the technique with detailed annotations

Concise summary of approach and listing of all reagents and special equipment

Full recipes for required reagents plus recommended storage and safe practices

Commentaries on background information ... literature review ... critical parameters ... troubleshooting ... anticipated results ... time considerations ... key references ... and more

Special techniques covered ...

- Convergent-beam electron diffraction
- Immunocytochemistry
- Ion-beam preparation methods
- Cryo-preparation methods
- Image storage, reconstruction and analysis

Every supplement will also include a special readers' "newsletter" featuring questions and comments from users.

Special Update Service

You won't have to wait years for the best new techniques to filter down to you or have to search them out in journals. With PROTOCOLS IN ELECTRON MICROSCOPY the best new protocols are presented to you every six months.

To be published Summer 1991

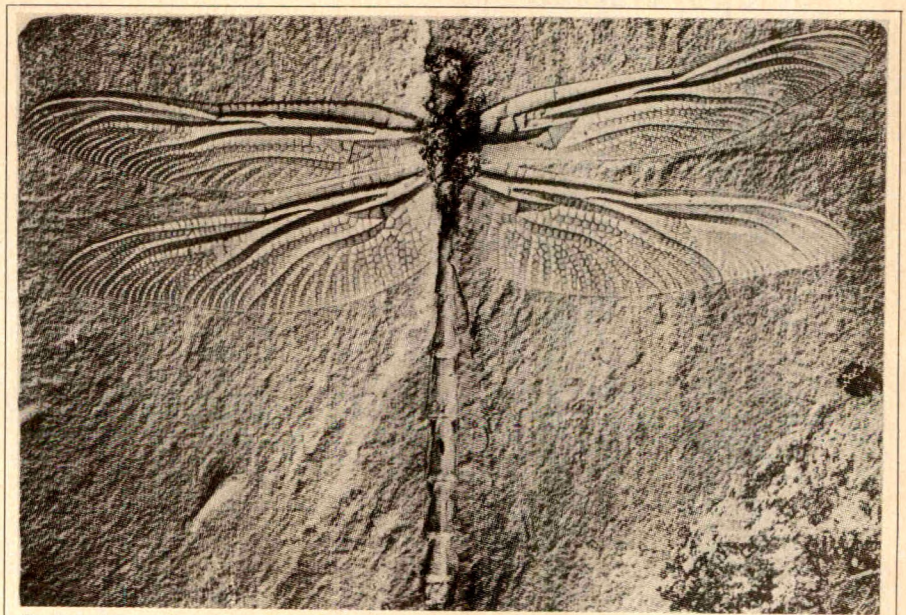
A fitting endeavour

Chris Brand

Genes, Culture and Personality: An Empirical Approach. By L. J. Eaves, H. J. Eysenck and N. G. Martin with contributions from R. Jardine, A. C. Heath, L. Feingold, P. A. Young and K. S. Kendler. *Academic: 1989. Pp.465. £32.50, $65.*

"THE post-1968 New Left in Britain and the United States has shown a tendency to see human nature as almost infinitely plastic, to deny biology and acknowledge only social construction." So much was admitted by Rose, Kamin and Lewontin, the left-wing co-authors of *Not in Our Genes* (Pantheon, New York/Penguin, London; 1984), as they nevertheless told psychologists to acknowledge complex biological influences on development lest the vacuum of New Left environmentalism should encourage old-fashioned biological determinism and simplistic hereditarianism. The present co-authored volume, in preparation over the past 15 years, is a much needed attempt to deliver the required psychogenetic sophistication in accounting for human personality differences.

Essentially, Eaves *et al.* indicate the possibilities of tracing questionnaire scores to at least some of the sources of variance envisaged by the population geneticist: to additive genetic factors that make closer relatives more similar, to 'between-family' environmental differences such as social class, to 'within-family' origins of differences between siblings, to assortative mating by parents that maintains extreme values of traits in the population, and the rest. To realize such possibilities, the authors repeatedly fit various models, involving varying hypothetical values for such parameters, to data from large twin and adoption studies conducted in London, Sweden and Australia.



Necessarily, the book is replete with tables and formulae; but, as champions of the non-simplistic might expect, really convincing conclusions are hard to find. The authors' main conclusion, however, which has become conventional wisdom amongst psychogeneticists in the 1980s, is clear. It is that families have few general environmental ('between-family') effects on the personalities of children reared in them — quite contrary to popular, and probably to 'New Left' belief. At least, most families' children vary widely in 'neuroticism', 'extraversion' and 'psychoticism'; the admittedly greater similarities between siblings in social attitudes may be attributable to assortative mating; and the well-known (though slight) effects of family environment on IQ do not concern the present authors.

Most readers, however, will find it hard to be persuaded of even that main conclusion of the book, until they reach page 127. Here, a revealing table sets out the astonishingly low correlations that the authors find not only between foster siblings, between nieces and aunts, and between fathers and sons, but even between fraternal twins who grew up together. For example, male fraternal twins in these London data correlate on average at only +0.07 across four different personality measures. Here, at last, there is little need for formulae and models to explain what is happening. Yet the authors prefer to press ahead with their modelling exercises rather than discuss the immediate implications of their remarkable raw data. Equally strangely, the table does not provoke the authors to consider that their only strong correlations (of around +0.53, between male identical twins) cry out for explanation in terms of epistasis (gene–gene interaction) which predicts substantial similarities between relatives only if a large percentage of relevant genes is held in common.

Why do Eaves and his colleagues tend to hide behind their formulae and models, and decline to provide compelling discussions of data even when opportunity knocks? One problem, admitted on the penultimate page of the book, is that their methods and data simply do not allow the handling of putative genetic–environmental interaction effects. Nor can readers be given much indication as to whether genetic–environmental covariation is at work. So the authors may have deemed it better to press on with fitting such models as they could. Another problem is the unrepresentativeness of their subjects — many of the London twins were recruited via a particular David Frost TV programme, for example.

Yet even with the help of volunteer samples of twins — which are bound to over-represent phenotypically similar identical twins who will understandably have more interest in twin research — the authors are only claiming a modest acquaintance with the causation of variables selected over some 40 years (in Hans Eysenck's programme of work) as seeming capable of yielding to scientific endeavour. What has happened here is that proponents of *nomothetic*, scientific approaches to human psychological differences are losing, at half time, by their own scrupulosity, to their classic opponents, the champions of *idiographic*, individuality-acknowledging approaches to personality. For the present, only IQ is left as a variable that behaves like a paradigmatic nomothetic personality trait — yielding greater phenotypic similarities in closer relatives. In contrast, much of the rest of adult personality now appears to emerge by magic.

These authors' evasiveness and compulsive model-fitting constitute one

On the wing — *Protolindenia wittei*, a fossilized true dragonfly with a wingspan of more than 10 cm. (Jurassic, Solenhofen, Germany.) Insect wings are thought to have developed from flaps on the first three thoracic segments; insects fully equipped for flight have been found as early as the Lower Carboniferous. Some species of ancestral dragonflies had wingspans of 70–76 cm. Like true dragonflies, they were swift flying predators with spiny legs used in capturing prey. The picture is taken from *The Fossil Book: A Record of Prehistoric Life* by Carol Lane Fenton and Mildred Adams Fenton, published by Doubleday.

legitimate response to the undermining of simple determinism about personality; but there is another. Conceivably, Eaves *et al.* might dispute the arguably modish terminology of 'transaction', 'emergenesis' and 'chronogenesis' which some writers in the 1980s have more daringly used to begin to describe how genes, in combination, might do their 'magic' (partly environment-shaping) work during psychological development. As it stands, however, the book contains little discussion of the work and theorizing of Sandra Scarr, R. J. Rose, Robert Plomin, David Lykken and Tom Bouchard. This unwillingness to join the 1980s hunt for an explanation of within-family variance is a disappointment — reflecting partly, of course, the book's long gestation period and the degree of international co-operation that was involved.

Nevertheless, the authors have produced a scholarly fulfilment of the best hopes of *Not in Our Genes* and can reasonably hope to provide more engaging theoretical analyses in future with the help of their substantial databases. Simple hereditarianism has at least proved easily superior to simple environmentalism; and more complex genetic effects are set fair to pick off the rest of personality variance. □

Chris Brand is in the Department of Psychology, University of Edinburgh, Edinburgh EH8 9JZ, UK.

Genetics of Neuropsychiatric Diseases

Edited by **Lennart Wetterberg**
Department of Psychiatry, St Goran's Hospital, Stockholm, Sweden

In the search for genetic links to schizophrenia and other etiologically unclear neuropsychiatric diseases, it is useful to learn how genes have already been mapped and genetic defects discovered in some related diseases. **Genetics of Neuropsychiatric Diseases** includes examples of both.

Also included are a gene map of neuropsychiatric disorders and diseases, enzymes and proteins of neuropsychiatric interest, as well as reports on DNA techniques and DNA linkage, and chromosomal aberrations as tools for gene mapping.

The book also discusses the research findings and clinical practice of several diseases. New techniques and the recent finding of a gene segment linked to schizophrenia are reviewed.

On the darker side

John Dunster

Multiple Exposures: Chronicles of the Radiation Age. By Catherine Caufield. *Secker & Warburg, London/Harper & Row, New York: 1989. Pp. 304. £12.95, $19.95.*

THE first thing to say about *Multiple Exposures* is that it grips. I found myself over half-way through at my first sitting with no more than trivia on my note-pad — the initial account of the discovery and early applications of X-rays and radioactivity combines detail and interest in a masterly way.

Most of the rest of the book is based on American experience, with occasional forays into the international scene. The emphasis is on the building and testing of nuclear weapons and the developing use of radiation in medicine, the author stepping back at intervals to look at the formulation of radiation-protection principles and policy. The selection is a little capricious. Nuclear electricity and nuclear propulsion of warships are barely mentioned, and then only in relation to accidents, and the use of radiation in industry and research is ignored. Nevertheless, the story is told well and accurately; although there are errors, most of them are harmless and do not detract from the main theme.

Perhaps the main weakness of this book is its principal title. Not until Chapter 20 does the idea of multiple exposures appear, and it never has more than a minor part. In fact, the system of radiological protection is specifically aimed at taking account both of single sources and multiple exposures (would that the control of toxic chemicals could be as effective!). All of the examples of failure in the book result from inadequate protection for single sources.

One of the book's important contributions is brought out first in the preface, in which Caufield clearly presents the perennial problem of conveying precise scientific information to the public without sounding either shifty or overconfident. She understands well the problems of setting standards for hazardous agents that may have no level of exposure that is totally risk-free, and also demonstrates the human capacity for letting blind belief and self-interest triumph over observation. Her quotations from the early enthusiasts for the benefits of X-rays and radium are chilling. But any sense of modern superiority can be dispelled by a visit to the local chemist's shop with a call at a health-food store on the way. Blind faith is still with us, though the dangers seem to be more limited.

In the third and fourth parts of the book, my initial enthusiasm became tempered by two concerns. The first was the selective nature of the "Chronicles". History is always selective, and authors of good historical books declare the basis of their selection. Caufield doesn't. Her choice of examples seems to be aimed at identifying only the harm done by radiation and by the practices that use or produce it. There is nothing wrong in that, but it would have been better to acknowledge it.

My second concern is more serious. Whenever a quotation emphasizes the dangers of radiation, it is subtly enhanced. Comments that might reassure are made to sound biased. In its worst form, this tendency takes the form of hinting that anyone who makes a statement about radiation risks or standards that is not hostile to governments or industries is deliberately supporting those governments or industries. Despite her understanding of the need to balance the risks to those exposed against the benefits to society, the author is unwilling to recognize that some people might oppose tighter standards because they believe that further restrictions would genuinely do more harm than good. One of the hard facts of life in work on safety and health protection is that all protective measures do some harm as well as some good. Increasing the good, considered in isolation, is easy if money is no problem, but getting the right balance between good and harm is very difficult indeed. Where limits are concerned, lower is not always better, and virtue is not confined to those who oppose the established views.

A book review is no place for me to defend either the International Commission on Radiological Protection (ICRP), of which I am a member, or the National Radiological Protection Board (NRPB), of which I was once Director, but two silly mistakes in the book need correcting. ICRP did not introduce the concept of ALARA (As Low as Reasonably Achievable) in 1977, and never used it to avoid reducing dose limits, although it does decrease their importance. The idea of ALARA goes back at least to the 1950s, was firmly established by 1965 and was the subject of an ICRP report (Publication 23) in 1973.

As to the second error, Caufield visited

• This autumn, W.W. Norton is issuing paperback editions of the following books in Britain. *Cosmic Dawn: The Origins of Matter and Life* by Eric Chaisson. £6.50. (For review see *Nature* **336**, 291; 1988.) *Longing for the Harmonies: Themes and Variations from Modern Physics* by Frank Wilczek and Betsy Devine. £7.95. (*Nature* **333**, 220; 1988.) *Oasis in Space: Earth History from the Beginning* by Preston Cloud. £12.95. (*Nature* **331**, 313; 1988.)

NRPB and knows that the Board is an advisory body. It could never have "directed that the dose limit for workers be immediately reduced from 5 rems per year to 1.5 rems per year" (p. 247). Indeed, it did not even recommend such a reduction. It did suggest that, *while the limits remain at their present level*, it would be prudent to adopt some time-averaged restriction so as to achieve an *average* effective dose equivalent of 15 mSv per year.

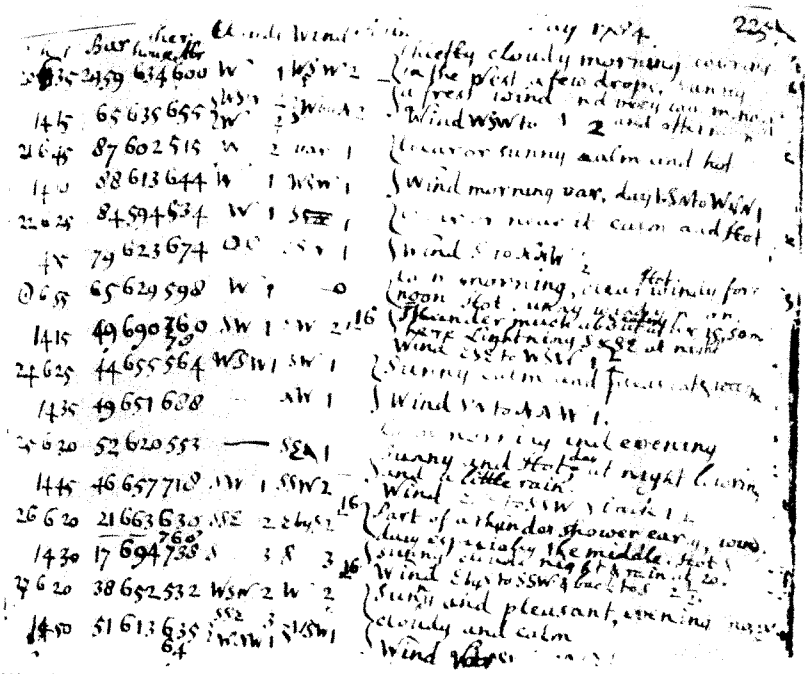
This is a good book, one that deserves a wide audience. It does not tell the whole story, nor is it without bias. But then, books without bias make dull reading, which is not a charge that can be levelled at Catherine Caufield. □

John Dunster, 52 Thames Street, St Ebbes, Oxford OX1 1SU, UK, was formerly Director of the National Radiological Protection Board.

In the country

John S. Perry

The Weather Journals of a Rutland Squire: Thomas Barker of Lyndon Hall (1722–1809). Edited by John Kington. *Rutland Record Society, Rutland County Museum, Catmos Street, Oakham LE15 6HW, UK: 1989. Pp.217. Pbk £16.50.*



In the journals of the Squire of Lyndon Hall, 1751 was a year "all on the extreams". His bees had been "so weaken'd by the cold and wet mid May which hindered their working for their numerous young ones, that without feeding them . . . several would have dyed". Oats were 12 shillings a quarter in the British Midlands "country" of Rutland. In other countries, the French vintage was bad; earthquakes troubled Finland; droughts beset Italy and Carolina. But in Rutland, 2.656 inches of rain were to be found in the Squire's cistern gauge, situated 7 ft 3 inches above the ground.

Employing no doubt the same scrupulously legible round hand of even the earliest of his journals, the Squire in later years communicated to the Royal Society's *Philosophical Transactions* not only the weather of Lyndon Hall, but also his calculations of comets' orbits and astronomical inferences from Eratosthenes and Ptolemy. To other audiences he presented his theological views on the benefits of baptism.

Thomas Barker, grandson of William Wiston, Newton's protégé and successor at Cambridge, emerges from the pages of this lovingly composed volume as a complex and vital man of his time, wedded to the soil of his comfortably self-contained "country" of Rutland, but intellectually linked with the larger worlds of politics, religion, science and, above all, nature. His life spanned the most eventful years of the eighteenth century, but little of that turbulence intrudes into the voluminous journals that he began as a teenager. His lifelong passion was the ever-changing weather, together with its effects on his agrarian world. Thus, his meteorological journals contain not only notes of the conventional variables of pressure, temperature, wind and precipitation, but also detailed accounts of storms, droughts, floods, crop yields, pests — a rich, moving panorama of his century that has provided a treasure trove for students of past climate.

John Kington, a climatologist at the University of East Anglia who studies eighteenth-century weather, has given us in this engaging little volume an ample selection of materials from the journals of Thomas Barker, together with brief but insightful sketches of the scientific and cultural worlds within which he lived, and the observational tools and methods he employed. Meteorology as a quantitative science was young. The barometer was less than a century old; the thermometer scarcely a half-century older. In 1723, when Barker was a toddler, the Royal Society began collecting weather journals from its members. But few of these records acquired the quality, continuity and wide dissemination of Barker's, which from 1771 were annually published in the *Philosophical Transactions*. Barker's reputation spread far beyond Rutland, for he was invited to contribute to an account of the severe winter of 1789–1790 being compiled by the Académie des Sciences of the unfortunate Louis XVI.

As Kington's account amply demonstrates, Thomas Barker was a pioneer in appreciating the importance of well-controlled, quantitative, continuous and extended observations in the study of nature. His journals show a keen awareness of the regularities of the British climate, and of the longer-term climatic fluctuations of his time. As a meteorologist of sorts, I stand in awe of Barker's insight and industry. But what sort of man was he? Some hints emerge from Kington's scholarship. A friend thought that marriage might relieve his "extreme Abstractedness & Speculativeness". At 61, he had a "streight belly", undertook a journey of 118 miles on horseback "without the least complaint or fatigue" and ran foot races with his son Samuel.

Weather report — an extract from the *Meteorological Journal 1777–1789* for May 1784, showing daily observations, made by Thomas Barker, of pressure, temperature, clouds, wind, rain and weather.

One leaves Kington's charming monograph with lasting respect for this trail-blazing climatologist — and with a wistful longing to know more of Barker the man. Whilst waiting for a fuller biography, I try to close the gap of centuries by picturing him in today's Rutland, now politically homogenized with "countries" he would have termed foreign. I see him at Lyndon Hall busily puttering away with his PC, his ham radio, his collection of tropical fish. Of course, Lyndon Hall's acres would be festooned with automatic weather stations. On his bookshelves, beloved classics would be joined by Kafka and Kundera, and he would no doubt struggle with enormous telephone bills and maintain lively correspondence equally with the *Times* and specialist journals. In the stables would stand his vintage Bugatti, next to his well-used Range Rover. This eighteenth-century man of the country would have been thoroughly at home as a twentieth-century man of science and the world. □

Does HIV cause AIDS?

"A dispute has broken out recently about the cause of AIDS. While the majority of virologists adhere to the common view that AIDS is caused by a virus that owes its name to this very belief, i.e., the Human Immunodeficiency Virus (HIV), a smaller number of heretics headed by the retrovirologist P. Duesberg, challenges this view. To express it in the words of the main opponents: "HIV causes AIDS!" (W. Blattner, R. C. Gallo and H. M. Temin) versus "HIV is a harmless, idle retrovirus that is not the cause of AIDS!" (P. Duesberg). In our time it has become quite rare that opposite positions are held so fiercely by highly respected scientists. There is public interest in a resolution of the controversy, since knowledge of the cause of disease is the basis of preventive measures." ■

Manfred Eigen contrasts these two views and discusses them critically in his article ***The AIDS Debate*** in the August issue of ***Naturwissenschaften.*** This monthly journal ranks among the most frequently cited in the natural sciences and is a journal of international importance. ■ If you are interested in the article or in more information about ***Naturwissenschaften,*** please write to: Springer-Verlag, 'Naturwissenschaften', P. On the bench

Lisa Steiner

Antibodies: A Laboratory Manual. By Ed Harlow and David Lane. *Cold Spring Harbor Laboratory Press: 1988. Pp.726. Spiral-bound $50.*

"It is only shallow people who do not judge by appearance" said Oscar Wilde. The mere look of *Antibodies* struck a positive chord, which puzzled me until I realized that it was due to the resemblance of the book to the familiar and indispensable *Molecular Cloning* (by Maniatis, Fritsch and Sambrook), also published by Cold Spring Harbor Laboratory Press. Indeed, the authors begin their preface with the comment that, inspired by the "cloning manual", they aim to put current immunochemical methodology into the hands of non-specialists. Happily, Harlow and Lane have succeeded admirably and this manual seems certain also to gain a place on the laboratory bench (too useful to remain on the bookshelf!) of a wide variety of biologists — even immunologists.

The volume opens with four introductory chapters summarizing key features of the immune response; these provide a succinct overview of the field and are very well written. The concepts of diversity, specificity, memory, clonal selection and tolerance are introduced with a minimum of fuss. The antibody molecule, its essential structural features that account for diversity and specificity, as well as the underlying genetic events, are economically surveyed. Antigen–antibody interactions are considered largely from the perspective gained from recent crystallographic analyses of complexes of monoclonal antibodies and protein antigens. The concepts of antibody affinity, avidity and multivalent binding, so important in applications, are also considered. Finally, the authors do a masterly job of discussing the essential features of antigen presentation and the role of B and T lymphocytes in the immune response, relating some of these basic principles to practical matters such as techniques of immunization. Each of the introductory chapters is accompanied by an up-to-date list of references.

The introduction is indeed a foretaste of good things to come. The scope of the rest of the book includes techniques of immunization and bleeding, monoclonal antibodies and hybridomas, protein labelling, immunoassays (mostly those using solid supports), immunoprecipitation of cellular antigens, immunoblotting and immunoaffinity purification. There are also four appendices containing much useful information: methods for running SDS gels, including a comparison of the sensitivities of autoradiography and fluorography, compilations of data about proteins and amino acids, and a thoughtful selection of "general information".

The "oversimplifications and omissions" mentioned in the introductory chapters did not trouble me, with perhaps one exception: the lack of distinction between the terms antibody (a molecule that reacts specifically with a particular antigen) and immunoglobulin (essentially the family of all antibodies, regardless of specificity). Although the authors do state that they will not make this distinction, not everyone will read — or remember — this disavowal, and references to "pure antibodies" or "purification of antibodies" are frequently ambiguous. The problem is partly but imperfectly corrected by use of the term "specific antibody".

The methods are presented as easy-to-follow "1–2–3 protocols", and assume relatively little experience. Rationales for procedures are often presented, which helps to remove some of the mystique that has often been associated with immunological methodology. Although it is hazardous to evaluate a cookbook without getting into the kitchen, the descriptions of techniques seem mainly clear and reasonable, and there are only a few, generally minor, errors. Key references are given and there is an extensive list of them at the end of the volume (though it is not correlated with the various procedures). In some cases, more specific documentation would have been helpful. For example, Table 3.1 lists affinity values required for several common immunochemical techniques. Such data are not easy to obtain and I would have liked to have been able to look up the sources. In the section "Making Weak Antigens Strong", it would have been worthwhile to include examples of the use of antigen modification to enhance immunogenicity: only dinitrophenylation of actin is mentioned, and that without a reference.

Although acutely aware of the evolution in immunological technology, I am not sure I fully grasped its extent until I compared the contents of this manual with Kabat and Mayer's *Experimental Immunochemistry*, the techniques 'bible' for a previous generation of immunologists. Although *Antibodies* includes a chapter entitled "Immunoprecipitation", the quantitative precipitin reaction is not mentioned, nor will one find out how to do immunoelectrophoresis. And, unless I missed it, the word 'complement' does not appear. I venture to guess, however, that the usefulness of this volume will rival that of its distinguished predecessor. For current versions of more traditional methods, the reader must turn to other sources, and in the preface reference is made to some of them. □

ELECTRON MICROSCOPY REVIEWS

Subcellular and Biomolecular Structure

Editor-in-Chief: **J R HARRIS**, North East Thames Regional Transfusion Centre, Crescent Drive, Brentwood, Essex CM15 8DP, UK

Associate Editors: **R W HORNE**, School of Biological Sciences, University of East Anglia, Norwich NR4 7TJ, UK
and **WAH CHIU**, Department of Biochemistry, Baylor College of Medicine, One Baylor Plaza, Houston, Texas 770306, USA

UNIQUE EDITORIAL COVERAGE

Electron Microscopy Reviews provides critical, up-to-date reviews of new developments in the field of transmission- and scanning transmission electron microscopy of subcellular organelles, membrane fractions, macromolecules and macromolecular assemblies from animal, plant, fungal and bacterial cells. Also included will be extracellular proteins and supportive structures, together with viral particles and their components. Emphasis is to be placed upon results and applications together with methodology. Reviews which include high resolution studies leading to two- and three-dimensional image analysis and reconstruction are particularly welcomed. The correlation of biophysical, biochemical, immunological and other data of a structural and functional nature with that derived from electron microscopy is encouraged.

The journal publishes material of the highest quality which has undergone strict editorial control. The production of all electron micrographs will be of a consistent high standard.

AN INVITATION TO CONTRIBUTE

The Editors welcome the submission of reviews for consideration. Text should be in English and between 5,000 and 20,000 words in length. Manuscripts should be typewritten, in double spacing throughout. Two copies of the entire paper should be sent to the Editor-in-Chief at the address above. Authors will be allowed a generous number of half tone figures in their articles. Reviews will be published in the shortest possible time, whilst maintaining a high standard of refereeing and quality of production. Full Instructions to Authors are available from the Editor-in-Chief.

Subscription Information

Published in two issues per annum (Volume 3, 1990)

Interaction between peptide growth factors and homoeobox genes in the establishment of antero-posterior polarity in frog embryos

A. Ruiz i Altaba & D. A. Melton

Department of Biochemistry and Molecular Biology, Harvard University, 7 Divinity Avenue, Cambridge, Massachusetts 02138, USA

The expression of the *Xenopus* homoeobox gene *xhox3* is an early response to mesoderm induction by peptide growth factors and the level of *xhox3* expression marks the antero-posterior character of the induced mesoderm. Different peptide growth factors specify different antero-posterior mesodermal cell fates as seen by the level of *xhox3* expression and the capacity to induce specific secondary neural/epidermal structures. These factors and homoeobox genes thus form part of the mechanism necessary for establishing antero-posterior polarity in the frog embryo.

POSITIONAL information for the antero-posterior axis of an amphibian embryo is first set out in the mesoderm[1] which in turn dictates antero-posterior differences in the overlying layer of ectoderm. Thus, an explanation of how the body plan of a frog tadpole is established depends in part on understanding how the embryonic mesoderm is formed and patterned.

Embryonic mesoderm is formed at the early blastula stage by an inductive interaction between endoderm and ectoderm[2] (Fig. 1). Recent studies show that this induction is likely to be caused by maternally encoded peptide growth factors (PGFs), including members of the fibroblast growth factor (FGF) and transforming growth factor-β (TGF-β) families[3-7].

Understanding the spatial patterning of the mesoderm is not straightforward because the torus of mesoderm of the blastula undergoes an extensive deformation as it invaginates during gastrulation (Fig. 1). Studies on early patterning have shown that dorso-ventral polarity is initiated by a rotation of the egg's cytoplasm shortly after fertilization[8,9]. Results from different experimental approaches have implicated the timing and extent of cell movements[10], inductive interactions between cells[11,12] and PGFs[3,4,13] in establishing mesodermal fates but have not resolved certain questions, such as whether the antero-posterior and dorso-ventral mesodermal fates are specified by the same or entirely independent mechanisms.

The *Xenopus* homoeobox gene *xhox3* is one of the first genes to be transcribed in the early embryo and is expressed in a graded fashion along the antero-posterior axis in the axial mesoderm[14] (Fig. 1*g*). Over-expression of *xhox3* prevents correct development of the anterior region where the gene is normally expressed at its lowest levels[15]. These findings have led us to suggest that *xhox3* is involved in interpreting positional information in the axial mesoderm along the antero-posterior axis. This raises the question of how the graded distribution of *xhox3* transcripts is first established.

Using the levels of *xhox3* expression as a mesodermal marker along the antero-posterior axis, we show here that different PGFs coordinately determine the level of *xhox3* messenger RNA and anterio-posterior pattern in the developing embryo.

Xhox3 expression is induced by PGFs

At the early blastula stage, vegetal (endodermal) cells induce overlying animal (ectodermal) cells to change their fates to become mesoderm. Animal cap cells from a blastula can be induced *in vitro* to form mesoderm by combination with blastula vegetal cap cells (the natural inducers[2]) or by incubation with PGFs (refs 3, 4). Analysis of *xhox3* expression in isolated animal and vegetal caps and recombinates shows that *xhox3* is transcribed only in recombinates (Fig. 2*a*). In this case, mesoderm induction is verified by the expression of a gene for muscle-specific actin (ms-actin)[16].

Incubating animal caps in either XTC-MIF, a *Xenopus* PGF-like mesoderm inducing factor of the TGF-β family[3,17], or basic fibroblast growth factor (bFGF)[4,5], results in the expression of *xhox3* mRNA (Fig. 2*b*). Notably, other factors such as platelet-derived growth factor, which is found in frog embryos[18], or retinoic acid, do not produce this effect. As before, *xhox3* expression is observed only when mesoderm induction has taken place, as confirmed by the expression of ms-actin RNA. Interestingly, *xhox3* expression is also seen when mesoderm induction is triggered intracellularly by the polyoma middle T antigen (ref. 19). This viral oncogene is thought to mimic an endogenous component of the signal-transduction pathway used by PGFs in mesoderm induction. Together these data show that PGFs induce the expression of *xhox3* in animal cap cells that have been induced to form mesoderm.

Xhox3 expression and mesoderm induction

Xhox3 expression in XTC-MIF- or bFGF-induced mesoderm is easily detected by the early gastrula stage (Fig. 2*c*). Expression of *xhox3* in mesoderm occurs very early and is transient, in contrast to the relatively late and permanent expression of a tissue-specific mesodermal marker such as ms-actin (Fig. 2*c*). For both of these genes, expression in induced animal caps follows the normal schedule of expression in unmanipulated embryos.

In several organisms, proto-oncogenes[20-22] and genes that contain a homoeobox[23-25] or zinc-finger[26] domain are expressed as an early response to a variety of inducing/activating agents. The expression of these genes, including *xhox3*, probably represents the activation of specific transcriptional programmes in response to a change in cell fate. Whereas *xhox3* expression is an early response to mesoderm induction, it is not sufficient on its own to cause mesodermal induction. The injection of synthetic *xhox3* mRNA can be used to direct ectopic expression of *xhox3* in animal caps, but this does not induce mesoderm (data not shown).

Mesodermal tissue induction by PGFs

It has been suggested that FGF- and TGF-β-related growth factors are ventral and dorsal mesoderm inducers, respectively[3-5]. This notion is based primarily on two observations. First, bFGF induces mostly muscle, some blood and, rarely, notochord[4,27], whereas XTC-MIF induces a great deal of muscle and notochord[3,17]. Thus, the mesodermal tissue induced by XTC-MIF is more dorsal than that induced by bFGF. Second,

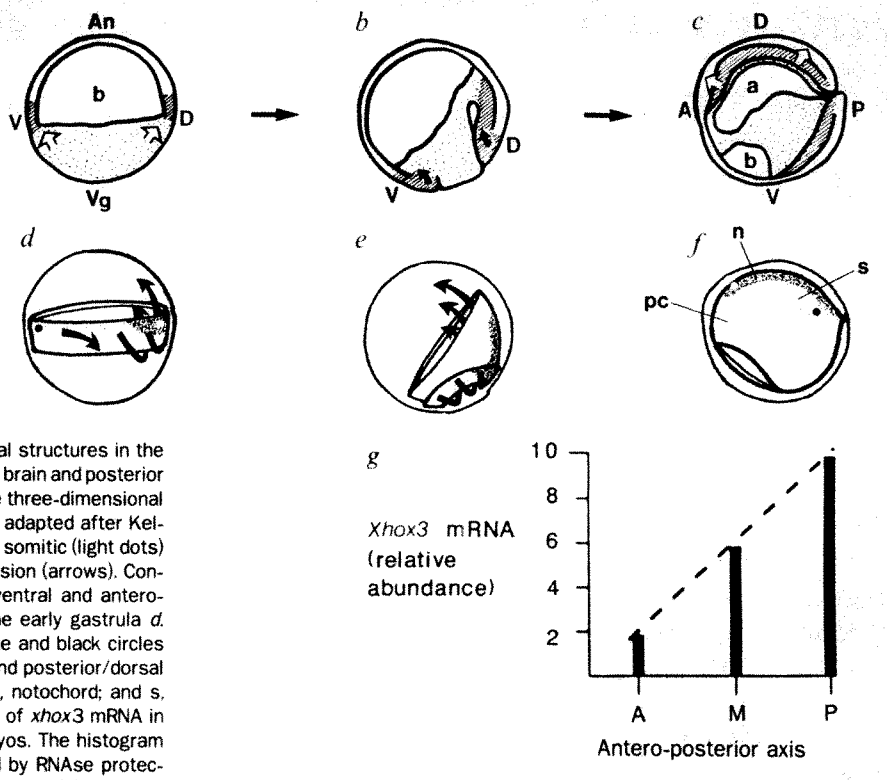

FIG. 1 Drawings of *X. laevis* blastula and gastrula embryos showing inductive and morphogenetic events. *a*, Mesoderm (hatched area) is formed in the blastula by an inductive interaction (open arrows) between endoderm (dotted area) and ectoderm (white area) along the animal (An)-vegetal (Vg) axis. The induced mesoderm forms a torus around the vegetal end of the blastocoel (b) as shown in *d*. *b*, Differences in the dorso-ventral axis established shortly after fertilization are evident in the different gastrulation movements (solid arrows) of dorsal (D) and ventral (V) mesoderm. Dorsal mesoderm invaginates first and migrates farther. *c*, At the end of gastrulation, the dorsal axial mesoderm has finished its invagination, creating the antero-posterior axis and forming the archenteron (a), the primitive gut. Note that the blastocoel is pushed ventrally during gastrulation. By this time, the axial mesoderm has induced neural structures in the overlying dorsal ectoderm; anterior (A) mesoderm induces brain and posterior (P) mesoderm induces spinal cord (open arrows). *d–f*, The three-dimensional aspects of mesodermal movements during gastrulation, adapted after Keller[10]. Note that prospective notochordal (heavy dots) and somitic (light dots) mesoderm is drastically rearranged by convergent extension (arrows). Consequently, the orthogonal relation between the dorso-ventral and antero-posterior axes of the late gastrula *f* is not found in the early gastrula *d*. As an example, the dorsal and ventral positions of white and black circles in the early gastrula are converted into anterior/dorsal and posterior/dorsal positions in *f*, the late gastrula. pc, Prechordal plate; n, notochord; and s, somitic mesoderm. *g*, Diagram of the graded expression of *xhox*3 mRNA in the axial mesoderm of late gastrula-early neurula embryos. The histogram shows the relative abundance of *xhox3* mRNA assayed by RNAse protection[14]. The highest value corresponds to the posterior third (P) and was equated arbitrarily to 10 and the values for middle (M) and anterior (A) parts were set proportionately. *Xhox3* is expressed in the mesoderm of the early gastrula but its distribution in the prospective axes has not been determined.

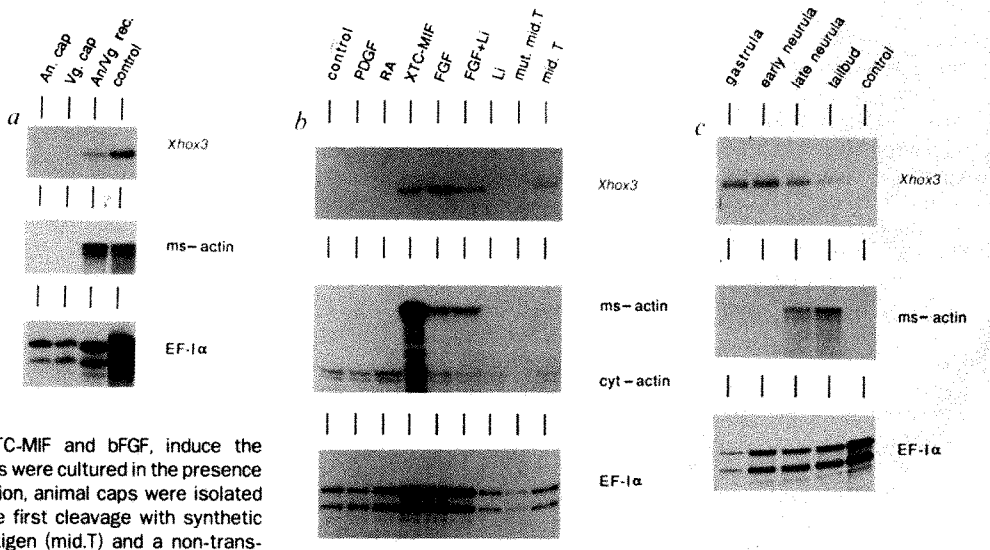

FIG. 2 Expression of the homoeobr gene *xhox3* is an early response to mesoderm induction by peptide growth factors. *a*, *xhox3* mRNA expression in animal/vegetal recombinates (An/Vg rec). Animal and vegetal caps from dissected blastula were cultured in isolation or in combination and allowed to develop to the equivalent of the neurula stage. RNase-protection assays were performed for transcripts from the genes encoding *xhox3*, muscle-specific (ms) actin (a mesodermal marker), and elongation factor (EF)-1α (ref. 47), a translation factor expressed in all embryonic cells which therefore serves as a control for RNA recovery. The control lane is RNA from neurula. *b*, Peptide growth factors that induce mesoderm, XTC-MIF and bFGF, induce the expression of *xhox3* RNA. Isolated animal caps were cultured in the presence of a variety of PGFs or morphogens. In addition, animal caps were isolated from embryos that had been injected before first cleavage with synthetic mRNA coding for the polyoma middle T antigen (mid.T) and a non-transforming mutant (NG59) of middle T (mut.mid.T) as control[19]. In all cases, RNA was isolated after the animal caps reached the equivalent of neurula stage and analysed by RNAse protection, as above. Cytoskeletal actin (cyt-actin) was a control for RNA recovery. Untreated animal caps were included as negative controls. RA, retinoic-acid. *c*, *Xhox3* expression is an early response to mesoderm induction by PGFs. Isolated animal caps were treated with XTC-MIF and allowed to develop for different times; RNA was isolated and assayed for the presence of *xhox3*, ms-actin and EF-1α encoding mRNAs. Untreated caps were processed as negative control. The increase in the level of EF-1α transcripts between the mid gastrula and early neurula stages is due to new transcription of this gene after the mid blastula transition[47].

METHODS. *X. laevis* embryos were cultured in 0.1 ×MMR (10 mM NaCl, 0.2 mM KCl, 0.1 mM $MgSO_4 \cdot 7H_2O$, 0.2 mM $CaCl_2 \cdot 2H_2O$, 0.5 mM HEPES, pH 7.6, 0.01 mM EDTA) and animal or vegetal caps were cut at the late blastula stage in the presence of streptomycin and penicillin on agarose dishes. Recombinates were made by joining the inner surfaces of animal and vegetal caps and allowing them to fuse. Treatment of the isolated animal caps was as follows: recombinant human PDGF was used at a final concentration of 50 $\mu g\ ml^{-1}$, bovine bFGF at 50 $\mu g\ ml^{-1}$, partially purified frog XTC-MIF at a 1:50 dilution, and retinoic acid at 10^{-5} M. Lithium ion was applied at the early blastula stage by incubating whole embyros in 0.25 M lithium chloride for 8 min. This treatment reproducibly produced the development of anteriorized embryos which develop only heads[30]. These embryos were rinsed in 0.1 ×MMR and animal caps were cut at the blastula stage. Synthetic mRNAs were injected before first cleavage at ~4 ng per egg. RNA extraction and quantitative RNAse protection assays using probes for all these genes are described elsewhere[14,48]. RNA from ten, three and one-half animal cap equivalents was used for the *xhox3*, actin and EF-1α assays, respectively. Exposure periods were for one week (*xhox3*), overnight (actin) and a few hours (EF-1α). Only the relevant protected fragments from the autoradiographs are shown.

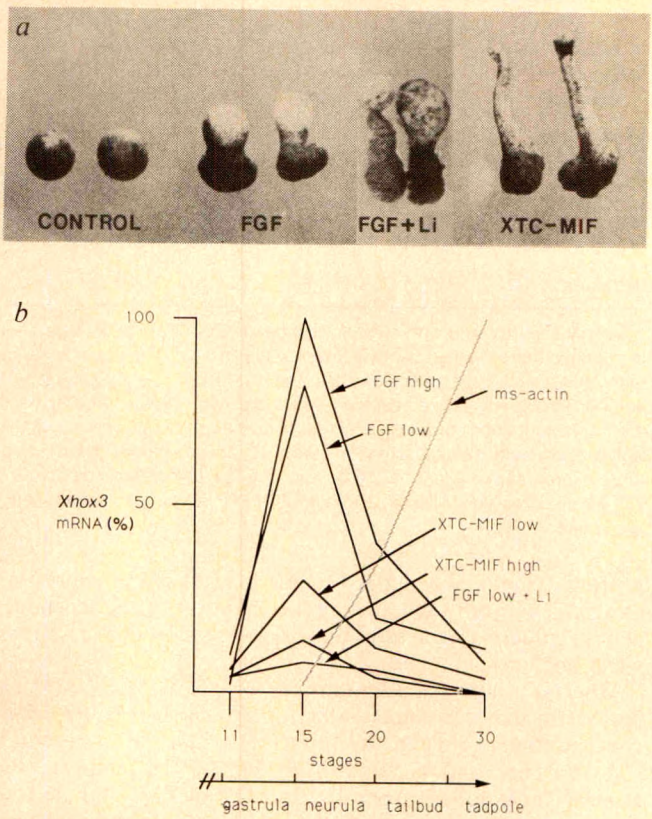

FIG. 3 Different peptide growth factors induce different levels of *xhox3* mRNA. *a*, Elongation of animal caps treated with bFGF at 50 $\mu g\ ml^{-1}$, bFGF at 50 $\mu g\ ml^{-1}$ plus lithium and XTC-MIF at 1:50 dilution. The controls are untreated animal caps. All caps were photographed at a time corresponding to the end of gastrulation (stage 13). *b*, Expression profile and quantitation of *xhox3* mRNA in caps treated with bFGF, bFGF plus lithium and XTC-MIF at different concentrations. Groups of 50 isolated animal caps were treated and time points collected at different stages. RNA was subsequently isolated and assayed by RNase protection for the presence of *xhox3*, actin and EF-1α mRNAs as noted above. Only the results for the *xhox3* protections are shown in the graph after densitometry and normalization. In all cases, PGF-induced mesoderm expressed ms-actin as shown for one case only (bFGF at 50 $\mu g\ ml^{-1}$ is shown, dotted line). FGF high, 200 $\mu g\ ml^{-1}$; FGF low, 50 $\mu g\ ml^{-1}$; XTC-MIF high, 1:50; XTC-MIF low, 1:200. Embryonic stage numbers refer to Nieuwkoop and Faber stages[49]. *c*, Representative results from RNAse protection assays. The expression profiles for *xhox3*, ms-actin and cyt-actin mRNA after induction bFGF at 50 $\mu g\ ml^{-1}$ and XTC-MIF at 1:50 are shown on the left. XTC-MIF induces lower levels of *xhox3* mRNA even though it induces larger amounts of ms-actin. The cross notes a residual amount of undigested probe. The right panels show the expression profile of *xhox3* mRNA in caps treated with bFGF (50 $\mu g\ ml^{-1}$) or with bFGF (50 $\mu g\ ml^{-1}$) plus lithium. Both panels are part of the same gel and the kinetics of *xhox3* expression is the same; only the level of *xhox3* mRNA varies. Embryonic stages are shown at the top of each gel lane. Stages are as in *b*.

animal caps treated with XTC-MIF elongate more than those treated with bFGF (ref. 28) (Fig. 3*a*), mimicking the different movements of prospective dorsal and ventral mesodermal cells during gastrulation[8,10].

Whereas varying doses of XTC-MIF and bFGF clearly induce different dorso-ventral mesodermal tissues, at high doses, when both PGFs induce dorsal mesodermal tissues (muscle), the caps elongate differently (Fig. 3*a*). As described earlier (Fig. 1), differences in elongation cannot be easily attributed to either dorso-ventral or antero-posterior differences in fate[8,10], which raises the possibility that XTC-MIF and bFGF affect both fates. For example, it is possible that these PGFs induce a state that enables mesodermal cells to acquire a specific dorso-ventral and antero-posterior fate during gastrulation.

Xhox3 mRNA induction by PGFs

To test for the induction of dorsal mesoderm with different antero-posterior character, we probed for the level of *xhox3* mRNA at the early neurula stage, when *xhox3* expression shows clear antero-posterior differences in normal embryos[14]. In these experiments, both XTC-MIF and bFGF were used at concentrations that induce dorsal mesoderm in animal caps, as judged by the expression of ms-actin. Figure 3*b* shows that bFGF induces higher levels of *xhox3* mRNA than does XTC-MIF. At any concentration of PGF sufficient to induce muscle, bFGF produces higher levels of *xhox3* mRNA than does XTC-MIF. Whereas the amount of *xhox3* RNA induced in XTC-MIF treated caps is lower than in those treated with bFGF, the expression of ms-actin is greater in the former (Fig. 3*c*). This indicates that the low amount of *xhox3* RNA in XTC-MIF treated cells is not due to the induction of fewer cells to become muscle as compared with treatment with bFGF.

The five- to tenfold difference observed in the amount of *xhox3* mRNA induced by XTC-MIF and bFGF is similar to the endogenous difference in *xhox3* mRNA levels between anterior and posterior mesoderm of the early neurula embryo[14] (Figs 1, 3). As high and low levels of *xhox3* expression are correlated with posterior and anterior determination, respectively[14,15], this suggests that high doses of bFGF induce dorsal/posterior mesoderm, whereas high doses of XTC-MIF induce dorsal/anterior mesoderm. Consistent with this, we note that increasing the dose of XTC-MIF does not increase, but rather decreases the amount of *xhox3* mRNA that is induced (Fig. 3*b*). Perhaps the highest XTC-MIF doses induce the most anterior mesoderm which, in turn, has the lowest level of *xhox3* mRNA (see Fig. 1).

Antero-posterior character of mesoderm

Treatment of blastula stage embryos with high doses of lithium gives the mesoderm a more anterior and dorsal character, whereas treatment with moderate doses results only in anteriorized mesoderm. In the latter case, the resulting embryos develop only head structures with normal dorso-ventral polarity[29,30]. Treatment with lithium alone has no effect on the development of isolated animal caps, but treatment with lithium plus bFGF results in more extensive elongation as compared with animal caps treated with bFGF alone[31] (Fig. 3*a*). This suggests the possibility that bFGF induces posterior mesoderm whereas bFGF plus lithium induces anterior mesoderm. This allows further testing of the correlation between *xhox3* levels and the antero-posterior character of the induced mesoderm.

The level of *xhox3* expression in bFGF-induced mesoderm anteriorized by lithium is lower than that observed in animal caps treated with bFGF alone (Fig. 3*b*, *d*). In both cases, ms-actin is expressed at high levels (data not shown). Notably, the difference in the levels of *xhox3* mRNA in these two cases is again about five- to tenfold (Fig. 3*b*), as with the antero-posterior difference in normal embryo mesoderm[14]. These observations strengthen the correlation between *xhox3* levels and antero-posterior mesodermal cell fates.

Testing for antero-posterior character

The experiments described above demonstrate that there is a good correlation between induction by a particular PGF and the level of *xhox3* RNA, but they do not directly test whether the mesoderm in PGF-induced animal caps is anterior or posterior. We have, therefore, directly tested the antero-posterior character of PGF-induced mesoderm by assaying its ability to induce specific antero-posterior secondary neural/epidermal structures. This is possible because the distinct epidermal and neural structures found along the axis are a direct reflection of antero-posterior differences in the underlying dorsal mesoderm which induces those ectodermal structures[1,11,32]. Dorsal mesoderm from an early gastrula (an organizer) can induce a secondary axis when grafted into the ventral marginal zone of a host embryo[1,33,34] (Fig. 4*a*). In a different assay, an organizer implanted into the blastocoel of a host embryo will induce anterior (head) structures (Fig. 4*b*) and sometimes a secondary axis. This latter assay was used to test the antero-posterior character of dorsal mesoderm from an early neurula salamander embryo[32]. It was found that anterior and posterior mesoderm induce the corresponding neural/epidermal structures after implantation, for example anterior mesoderm induces brain and eyes, whereas posterior mesoderm induces spinal cord and dorsal fin.

Implantation of animal cap pieces previously induced with high doses of XTC-MIF causes a secondary induction of anterior (head) structures as seen externally (Fig. 4*c*) and assayed histologically (Fig. 5*b*, *c*). Animal caps treated with bFGF induce the formation of posterior (tail) structures (Figs 4*d*, 5*d*); anterior structures are never observed. As a control, untreated animal cap material shows no inductive capacity in this assay (Fig. 4*e*). Thus, different PGFs induce mesoderm with different antero-posterior character as judged by the level of *xhox3* expression in animal cap cells and also by the character of the secondary neural/epidermal structures that are induced by this mesoderm when implanted.

Whereas high concentrations of XTC-MIF produce mesoderm that can induce anterior structures (Fig. 4), lower concentrations result in the induction of posterior structures similar to those induced by bFGF (Table 1). This indicates the existence of a graded response to the dose of XTC-MIF, as well as a graded distribution of XTC-MIF or a similar molecule along the antero-posterior axis. We note that secondary head

TABLE 1 Summary of *in vivo* transplantation experiments

Animal cap treatment	Induced secondary structures				
	Head	Trunk	Tail	Normal	Total
XTC-MIF 1:50	30 (52%)	7 (12%)	10 (17%)	11 (19%)	58
XTC-MIF 1:100	2 (7%)	6 (21%)	15 (54%)	5 (18%)	28
XTC -MIF 1:500	0 (0%)	0 (0%)	2 (12%)	14 (88%)	16
bFGF 50 ng ml^{-1}	0 (0%)	6 (10%)	38 (63%)	16 (27%)	60
bFGF 200 ml^{-1}	0 (0%)	2 (7%)	16 (55%)	11 (38%)	29
Untreated	0 (0%)	0 (0%)	1 (2%)	49 (98%)	50

Animal caps treated with different doses of XTC-MIF or bFGF were used in transplantation experiments as described in Fig. 4. The control was untreated animal caps transplanted to the blastocoel of early gastrula. All anterior structures such as cement glands and eyes were scored as head, most tails contained obvious caudal fins. In only a few cases were the heads well proportioned. The capacity of XTC-MIF to induce anterior (head) structures is progressively lost as the dose of the PGF is lowered: compare the XTC-MIF 1:50 to XTC-MIF 1:500. Results from 10 independent experiments are shown.

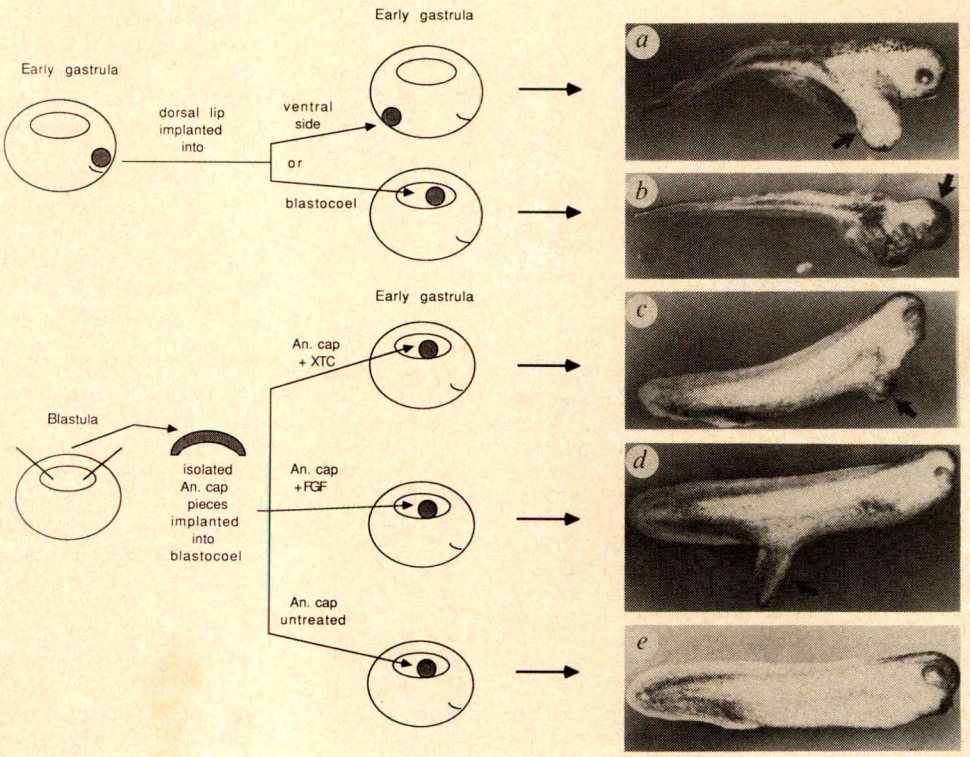

FIG. 4 Peptide growth factors induce mesoderm with different antero-posterior character as seen by the ability to induce different secondary neural/epidermal structures. The positional value of mesoderm is tested by grafting *a* or implantation *b*–*e* of mesodermal pieces into gastrulating host embryos. *a*, When the dorsal lip of an early gastrula (an organizer) is grafted to the ventral marginal zone of a host gastrula, an entire second body axis is induced *b*, When the same mesodermal region is implanted into the blastocoel, it is pushed ventrally during gastrulation and induces primarily head structures and sometimes whole secondary axes. Animal caps induced by XTC-MIF or bFGF were implanted into the blastocoel of sibling embryos at the early gastrula stage. Animal caps induced by XTC-MIF at high doses (1:50) can induce head structures *c*, whereas bFGF never induces head structures and only induces tail and trunk structures *d* even at high doses (200 μg ml^{-1}). *e*, Untreated animal caps have no effect following implantation as ectoderm is incapable of neural induction. Arrows show the secondary structures: in *a*, a whole axis; *b*, a head; *c*, a head with cement gland and optic cup, and in *d*, a tail with dorsal fin.

METHODS. Transplantation experiments were as described previously[32,33]. Animal caps were isolated at the early blastula stage and incubated with the appropriate growth factors in 1×MMR with antibiotics. At a stage equivalent to that of the early- to mid-gastrula stage, the ectodermal layer was peeled off and the induced mesoderm tissue was implanted into host early gastrula stage embryos through a small hole in the blastocoel roof. The size of the implants was equivalent to about half the size of a single animal cap. Host embryos healed within minutes and were allowed to develop in 0.1×MMR with the animal pole facing up. Dorsal marginal zones (organizers) were dissected from early (stage 10) gastrula and either implanted into the blastocoel or grafted to the ventral side of a sibling embryo after the extirpation of some ventral marginal zone cells.

and tail structures are always found at the host's anterior and posterior ends, respectively (see Figs 4, 5*a*). This could reflect antero-posterior differences in cell surface properties.

A given amount of *xhox3* mRNA is apparently necessary, but not sufficient, to specify antero-posterior position in mesoderm. For example, over expression of *xhox3* mRNA in the anterior end of normal embryos does not result in the production of posterior structures at the anterior end, but rather the failure to form normal anterior structures[15]. Also, even though the level of *xhox3* RNA can be lowered in bFGF-treated animal caps by treatment with lithium (Fig. 3), this anteriorized mesoderm does not acquire the ability to induce head structures in transplantation assays (data not shown). Thus, whereas the amount of *xhox3* RNA marks the positional value of mesoderm, changing *xhox3* RNA levels is not sufficient to change its antero-posterior character.

Mesoderm as a Spemann organizer

Grafting XTC-MIF induced animal cap mesoderm into the ventral marginal zone of a host embryo results in the formation of a secondary axis[35]. We find that when high concentrations of XTC-MIF are used to induce mesoderm, secondary axes are also observed following transplantation of the induced mesoderm into the blastocoel of a host (Fig. 5). This is the same result as that observed when a full organizer from the dorsal blastopore lip of an early gastrula is transplanted into the blastocoel or ventral marginal zone of a host[11,33]. Similarly, mesoderm induced by high concentrations of bFGF induces trunk structures (Fig. 4*d*, 5*d*). This corresponds to the results obtained following transplantation of a trunk organizer taken from the dorsal lip of a mid to late gastrula[1,36].

These experiments show that implanted animal caps treated with high doses of PGFs can redirect host ventral mesodermal cells to become dorsal with an antero-posterior character determined by the implant. Labelling the implant with a lineage tracer shows that most of the induced secondary mesodermal and neural structures are derived from host, not grafted tissue (Fig. 5*e–g*). Thus, treatment with PGFs not only induces mesoderm in animal cap cells, it endows this mesoderm with the properties of a Spemann's organizer, including dorsalization and neural induction[1,11,33].

Discussion

Endogenous PGFs of the FGF and TGF-β families probably induce embryonic mesoderm during early development[3–7,37,38]. This newly induced mesoderm must attain regional differences which lead to axial patterning and the development of different tissues such as notochord, muscle and blood. Our results with the homoeobox gene *xhox3* lead us to propose that PGFs not only act as morphogens that pattern the dorso-ventral axis, but also the antero-posterior axis. We note that other PGFs such as TGF-β1 are unable to induce mesoderm on their own, but can alter the response of animal cap cells to FGF[5,6]. Thus, there may also be several PGFs in in the embryo that act as patterning morphogens, but not mesoderm inducers.

The establishment of antero-posterior polarity requires a system of positional information[39] that specifies different fates for mesodermal cells according to their position at the end of gastrulation[8]. The system probably includes a diffusible graded signal[40] to account for the observed graded axial deficiencies in embryos obtained after perturbation by ultraviolet irradiation[41,42], gastrulation arrest[9] or *xhox3* over-expression[15]. Our results indicate that this graded signal is likely to be one or more PGFs, as varying the dose of PGF used to induce mesoderm results in a graded response both in the amount of *xhox3* mRNA induced and in the antero-posterior character of the mesoderm (Fig. 3 and Table 1). In fact, the graded distribution of *xhox3* transcripts observed in the axial mesoderm of

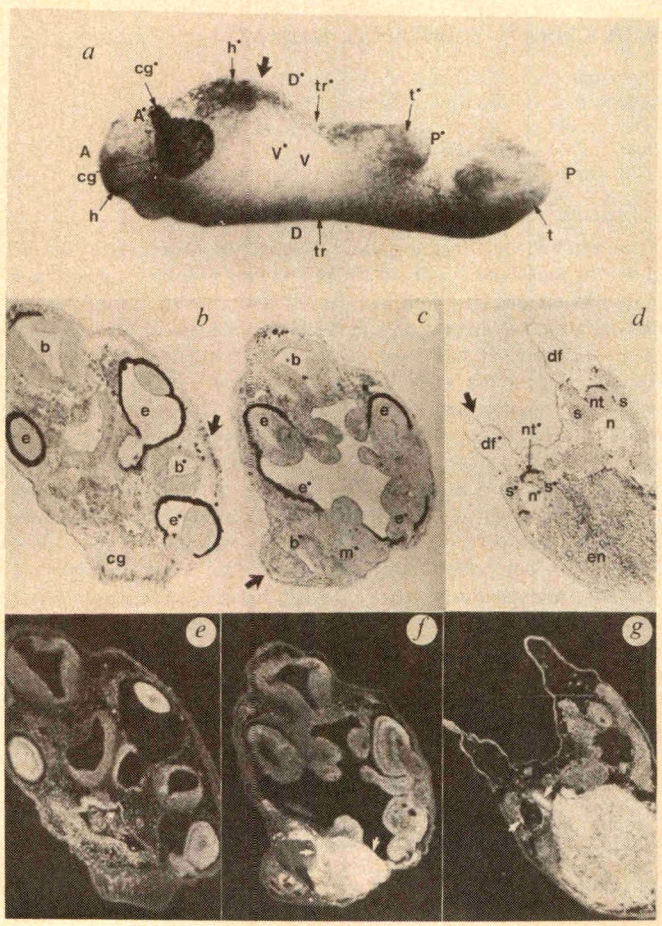

FIG. 5 Mesoderm induced in animal cap cells by peptide growth factors has the properties of a Spemann organizer. *a*, Animal cap cells treated with XTC-MIF (1:25–1:50) was implanted into the blastocoel of an early gastrula as shown in Fig. 4*c*. Ventral mesoderm and ectoderm of the host is induced to form a whole secondary axis including anterior, middle and posterior neural/epidermal structures. A ventral view of the host embryo shows the secondary axis (thick arrow) with secondary cement gland (cg), head (h), trunk (tr) and tail (t). All secondary structures are denoted by a dot superscript. Because the blastocoel containing the implanted mesoderm is pushed ventrally during gastrulation, the secondary axis usually appears ventral to the host axis and the two embryonic axes are joined at their ventral sides. Anterior is to the left. *b–g*, Histological analysis of secondary structures in three separate animals. These examples confirm the external identification of secondary anterior and posterior structures as shown in Fig. 4 and described in Table 1. Animal caps isolated from embryos injected with the lineage tracer FLDx (ref. 34) were induced to form mesoderm by XTC-MIF (1:50; *b*, *c*) or bFGF (100 μg ml^{-1}; *d*). As in *a*, PGF-induced animal cap material was implanted into the blastocoel of an unlabelled host embryo. After sectioning the whole animal, photographs of selected sections were taken under bright field (*b–d*) or fluorescent illumination (*e–g*). Sections in panels *b* and *c* demonstrate that the induced secondary heads contain well defined brain (b) and eyes (e) as well as mesodermal (m) tissues. Panel *d* shows a second dorsal fin (df), neural tube (nt), somites (s) and notochord (n) induced by an animal cap treated with bFGF before implantation. Thick arrows point to the midline of the secondary axes. *e–g*, The cells derived from the FLDx-labelled implanted mesoderm are identified by their fluorescence (white arrows). Note that in *e* all secondary structures are host derived whereas in *f* there is a mixture of host and implant material in the secondary axis. In *e*, the FLDx-labelled descendants of the implanted cells are found in other sections (not shown). In *g*, all secondary structures are host derived with the exception of part of the somites and notochord. The bright signal in the endoderm (en) in *g* is due to autofluorescence of the yolk.

early embryos may be a reflection of the graded distribution of PGFs. In addition to effects on the expression of *xhox3*, PGF gradients may regulate the mesodermal and neural expression of other frog homoeobox genes including *xlhbox6*, (ref. 43) *xlhbox1* (ref. 44, 45) and *xhox36* (ref. 46). Thus, gradients of PGFs could set positional information and polarity along the antero-posterior axis in the responding axial tissues by regulating the level of homoeobox gene expression. If this is the case, more needs to be learned about where endogenous PGFs are found and when (before, during or after gastrulation) they act. □

GRAVITATIONAL lensing has provided important information about the mass and density of the intervening galaxies which image more distant quasars, and has placed limits on the properties of massive objects which might perturb the microwave background. In most studies it has been assumed that the lensing object is stationary[1–3]; some work has been done on moving lenses, but these have mostly been concerned with the effects of motion on the light curve, particularly as caustics sweep past the observer[1,4,5], on the redshift pattern and surface brightness of a moving background[6–8], or as a cause of microlensing[9,10]. Here we point out several properties of moving lenses that do not appear to have been noted before: moving lenses always produce two-dimensional velocities; they impose specific relations between observed velocities and positions; they magnify relative source velocities; they convert linear into rotary motion; and they convert radial into transverse velocity. The mass and distance of a moving lens can be separately determined. We point out some useful astronomical diagnostic properties of moving lenses, for which the Very-Long-Baseline Array under construction will be particularly useful.

To derive new physical properties of moving lenses in a simple way we consider point-mass gravitational lenses and use the geometry and notation of ref. 11. The gravitational lens of mass M is characterized by a strength parameter

$$\mu = \frac{4GM}{c^2}\frac{l_{OD}l_{DS}}{l_{OS}} = \theta_0^2 l_{OD}^2 \qquad (1)$$

where l_{OD}, l_{DS} and l_{OS} are, respectively, the observer–deflector, deflector–source and observer–source distances, and θ_0 is the angular radius of the cone of inversion given by

$$\theta_0 = 2.9\left(\frac{M}{M_\odot}\right)^{1/2}\left(\frac{l_{DS}}{l_{OD}l_{OS}}\right)^{1/2} \text{ mas} \qquad (2)$$

with distances measured in kpc. If we project the source and image positions onto the deflector plane, then the distances of the source and image positions from the deflector, denoted by $\mathbf{r}$ and $\mathbf{r}_I$ respectively, are related by

$$\mathbf{r}_I = \mathbf{r} + \frac{\mu}{r_I^2}\mathbf{r}_I \qquad (3)$$

Consider a system in which the lens and the source move relative to one another. In the absence of the lens, the source would seem to move with coordinates $x(t)$, $y(t)$. To a first approximation, for short times, the source motion will be linear and we can choose the cartesian coordinate system such that $x = vt$ and $y = a$ = constant. Any more complicated lens or image can be built up by combining such fundamental solutions. Our simple example contains the essential physical properties of image motion and can be visualized easily.

The velocity components of images in the x_I and y_I direction, follow from equation (3):

$$V_{xI} = \frac{v}{2} \pm \frac{v}{2}\left(1 + \frac{4\mu}{a^2 + v^2t^2}\right)^{1/2} \mp \frac{vt}{2}\frac{4\mu v^2 t}{(a^2 + v^2t^2)^2}\left(1 + \frac{4\mu}{a^2 + v^2v^2}\right)^{-1/2} \qquad (4)$$

and

$$V_{yI} = \mp\frac{2a\mu v^2 t}{(a^2 + v^2t^2)^2}\left(1 + \frac{4\mu}{a^2 + v^2t^2}\right)^{-1/2} \qquad (5)$$

A striking feature of moving lenses is their ability to alter the source velocities significantly. Even though the source has a

constant velocity relative to the lens, the image will seem to accelerate. Although the source velocity can be one-dimensional in a suitably rotated coordinate frame for short times, lensed velocities are two-dimensional for any coordinate rotation. From equations 3-5, there is also an important relation at any epoch between the velocities (V_{xI}, V_{yI}) and the image coordinates (x_I, y_I):

$$V_{xI}=\frac{x_I}{t}+V_{yI}\frac{x_I}{y_I} \tag{6}$$

Furthermore, the two components of the image velocities yield the total squared transverse image velocity as a function of position

$$V_I^2\equiv V_{xI}^2+V_{yI}^2$$
$$=\frac{x_I^2}{t^2}\left[1-\frac{2x_I}{\mu}\frac{(x_I-vt)^2}{(x_I-vt/2)}+\frac{x_I^2+y_I^2}{\mu^2}\frac{(x_I-vt)^4}{(x_I-vt/2)^2}\right] \tag{7}$$

The right-hand side of equation (7) reduces to v^2 in the limit $\mu\to 0$. The relations given by equations (6) and (7) are a signature of a moving gravitational point lens. More complicated lenses will have analogous velocity-position signatures, appropriate for more specific models.

The ability of the moving lens to magnify source velocities appreciably, especially when source and lens are closely aligned along the line of sight, is apparent from equations (4) and (5), rewritten as

$$\frac{V_{xI}}{v}=\frac{1}{2}[1\pm(1+4\eta s)^{1/2}\mp 4\eta s(1-s)(1+4\eta s)^{-1/2}] \tag{8}$$

$$\frac{V_{yI}}{v}=-2\eta s^{3/2}(1-s)^{1/2}(1+4\eta s)^{-1/2} \tag{9}$$

where $\eta=\mu/a^2$ and $s=1/(1+\xi^2)$ with $\xi=vt/a$, considering v as constant for short periods.

Clearly V_{xI}/v can become arbitrarily large for sufficiently large values of η and small ξ. Figure 1 shows solid and dotted curves corresponding to V_{xI}/v and V_{yI}/v as functions of ξ, for a sample of values of $\eta=1$, 10, 100 and 1,000. The x and y components of the source velocities can be magnified by a substantial factor ($\gtrsim 5$) for values of $\eta\gg 10$ in the region $0\lesssim\xi\lesssim 1$. Thus it is conceivable that the source velocities could be magnified by an order of magnitude or more, as long as the position of the source is projected well within the cone of inversion. Part of the image may then exhibit an apparent superluminal motion.

A second effect of moving lenses is to convert linear into rotary motion, as velocities are magnified by different amounts in different directions. The angular change resulting from translational motion is $\Delta\theta\approx 20vt/l_{OD}$ mas, where v is units of 100 km s^{-1}, t is in yr and l_{OD} is kpc (for $4\mu(a^2+v^2t^2)^{-1}\ll 1$), which is measurable with very-long-baseline interferometry (VLBI) if the lens is in our galaxy. This is a conservative example because $\Delta\theta$ is magnified considerably when $\mu\gg a^2\gtrsim v^2t^2$.

The simplest example of the rotary phenomenon is illustrated by linear source motion for which the image trajectory in polar coordinates is

$$r_I=\frac{a}{2}\left(1+\frac{1}{\tan^2\theta_I}\right)^{1/2}+\frac{a}{2}\left(1+\frac{1}{\tan^2\theta_I}+\frac{4\mu}{a^2}\right)^{1/2} \tag{10}$$

with

$$\theta_I=\tan^{-1}\left(\frac{a}{vt}\right)$$

For $\mu=0$ only would the image of the source motion be undistorted. This provides a means of estimating μ by observation if the source moves linearly with constant velocity, at least for short times.

The rotation of more general source motions and of extended sources is illustrated in Fig. 2, which shows the images as the source moves along a straight line (grey solid or dotted areas). The corresponding images indicated by black filled and dotted lines give the impression of a rotary motion as the source moves from left to right relative to the gravitational lens. The impression of rotation is enhanced as the moving dark image beyond the cone of inversion seems to merge with the moving dark image within the cone of inversion. An observer unaware of the source motion is apt to connect, incorrectly, these two images and to interpret the result as a net rotary motion.

A consequence of rotary motion is that the conversion of

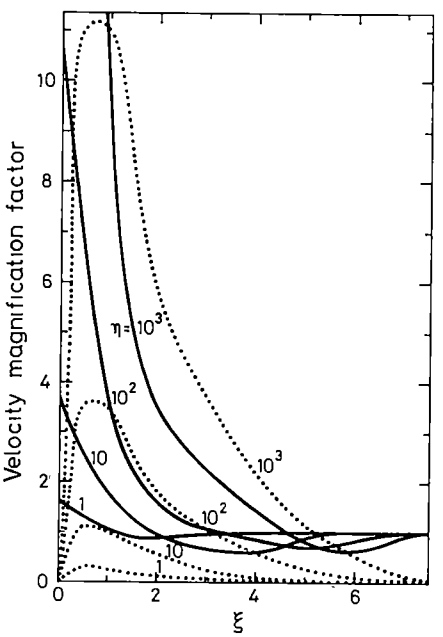

FIG. 1 The velocity magnification factors V_{xI}/v (solid lines) and V_{yI}/v (dotted lines) are shown as functions of $\xi=vt/a$ for values of $\eta=1, 10, 10^2$ and 10^3.

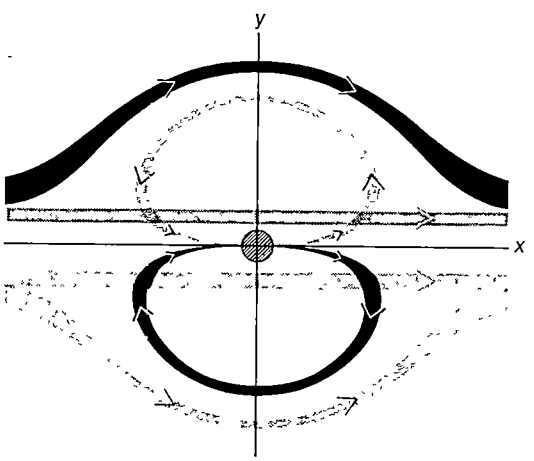

FIG. 2 Two straight line contours (solid and dotted) show the source motion parallel to the x-axis in the direction of the arrows. The corresponding external and internal images are indicated by dark and dotted contours, the hatched circle denotes the central deflector. The images marked by the arrows seem to give the impression of a rotary motion, as the source moves from left to right apparently merging the dark image outside the cone of inversion with the moving dark image within it.

uniform linear source motion is accompanied by an apparent acceleration. Some superluminal sources (for example, 3C345) seem to show accelerating components on VLBI scales[12], and it is conceivable that some observed superluminal velocities and accelerations could arise from lenses moving relative to the background components of a radio source.

A third feature of moving lenses is their ability to convert the radial component of a source's motion relative to the lens into a transverse component of image motion. This follows from equations (1) and (3) by letting μ vary as the deflector-source distance changes along the line of sight. From equation (1) we obtain

$$\mu = \frac{4GM}{c^2}\left(\frac{l_{OD}}{l_{OS}}\right)^2 \dot{l}_{OS} \tag{11}$$

and the velocity components given by equations (4) and (5), derived with a constant μ, are modified to

$$V_{xI} = V_{xI}\ (\mu = \text{constant}) \pm 5\times10^5 (M/M_\odot)\left\{\frac{l_{OD}}{l_{OS}}\right\}^2 v_r \frac{\xi s}{a(1+4\eta s)^{1/2}} \tag{12}$$

and

$$V_{yI} = V_{yI}\ (\mu = \text{constant}) \pm 5\times10^5 (M/M_\odot)\left\{\frac{l_{OD}}{l_{OS}}\right\}^2 v_r \frac{s}{a(1+4\eta s)^{1/2}} \tag{13}$$

Here the relative radial component of source velocity is $v_r = \dot{l}_{OS}$. This term adds to the transverse components V_{xI} and V_{yI} of the image velocities, and V_{yI} ($\mu \neq$ constant) can become significant relative to V_{xI} ($\mu \neq$ constant) if ξ is small and η is large, because $s/[a(1+4\eta s)^{1/2}] \approx \mu^{-1/2}$. In general this will be a small correction to V_{xI} or V_{yI} which is unlikely to be observable with present techniques, although conversion of radial into transverse motion is a novel astrophysical effect.

Observed image motions can determine the distance and mass of the lens, provided the source is much farther away than the lens, or if there is independent knowledge of the observer-source distance. It is possible, in principle, to determine the source position from the positions of the two images $(x_I^+(t), y_I^+(t))$, $(x_I^-(t), y_I^-(t))$ produced by a lens

$$x = vt = x_I^+(t) + x_I^-(t) \tag{14}$$

$$y = a = y_I^+(t) + y_I^-(t) \tag{15}$$

and hence obtain μ from the observed velocities or corresponding image positions. Having derived μ and measured θ_0 from the observed image configuration, we can infer the value of l_{OD} from equation (1) and of M from equation (2) if $l_{OD} \ll l_{OS}$ or if l_{OS} is known independently.

The quantities η, v and s can be related directly to observations. If the source lies within the cone of inversion given by the angular radius θ_0, then $\eta = \mu/\alpha^2$ is just the total observed intensity gain of the image[1]. Therefore a consistency check is provided by measuring a and μ from the positions and velocities of the two images and measuring η from the relative intensities at different epochs. Furthermore, velocity observations from four epochs can provide an independent determination of v, μ and η.

These ideas can be applied in a number of specific cases. Although the close alignments required for lensing generally have a very low *a priori* probability, they do occur. Lensed quasars, quasars behind the nucleus of a nearby galaxy and galactic stars in front of extragalactic radio sources[13] have all been discovered, usually by accident.

An interesting application is to the possible presence of a massive black hole, of a few million solar masses, in our galaxy's nucleus, for which there is significant, but not conclusive, evidence.[14,15] One way to infer its existence and properties would be to examine its influence on background sources such as radio clouds, jets and maser regions lying on the far side of the nucleus from us. Gravitational lensing phenomenon such as arcs or ring-like morphology at radio and infrared wavelengths would need to be confirmed by the velocity information we have discussed, because the complex structure of a galactic nucleus could also be due to phenomena unrelated to lensing.

For a black hole of mass M in the galactic nucleus, at a distance $l_{OD} = 10$ kpc, the typical angular image scale is, from equation (2):

$$\theta_0 = \left(\frac{M}{10^6 M_\odot}\right)^{1/2}\left(\frac{l_{DS}}{l_{OS}}\right)^{1/2} \text{ arcsec} = 5\times10^{-2}\left(\frac{M}{10^6 M_\odot}\right)\left(1-\frac{l_{OD}}{l_{OS}}\right)^{1/2} \text{ pc} \tag{16}$$

For a significant effect, the last factor would typically be ~0.5. Maps of the galactic centre in the infrared[16] and at 21 cm (ref. 17) show complex structure on scales $\geq$10 arcsec but, for these to be lensed images, the black-hole mass would have to exceed $10^8\ M_\odot$ for which there is no corroborating dynamical evidence. It is more probable that lens images will appear on much smaller scales ($\leq$1 arcsec) with radio and infrared interferometry. However, the necessary extensive multi-epoch VLBI and infrared mapping of our galactic nucleus on this scale has not yet been done.

The corresponding timescale for variations arising from the source motion with relative velocity v is

$$\tau = \frac{\theta_0 l_{OD}}{v} = 500\left(\frac{M}{10^6\ M_\odot}\right)^{1/2}\left(\frac{l_{DS}}{l_{OS}}\right)^{1/2}\left(\frac{v}{100\ \text{km s}^{-1}}\right)^{-1} \text{ yr} \tag{17}$$

Image variations with timescales less than several years, and observable with resolution $\geq$0.5 mas, include hot spots in relativistic jets, black-hole accretion-disk flares, supernova and related phenomena with relativistic speeds, positioned well beyond the nucleus. Moreover, phenomena such as colliding stars or pulsars (which would produce a pulsating ring if perfectly aligned) with intrinsically short timescales, can occur in the nucleus. On the other hand, a slowly moving source imaged by a low-mass black hole or microlensed by a star in the nucleus can appear to vary rapidly. As our line of sight through the galactic nucleus passes roughly through the galactic plane it may fortuitously intersect a suitable source in a spiral arm, even though the *a priori* probability is very small.

A second illustration is maser clouds, which radiate over a small bandwidth. Narrow band VLBI can measure the relative positions of features in a narrow radial-velocity range very accurately[18]. For example, a source with velocity 1 km s^{-1} at a distance of 1 kpc would move an angular distance ~0.14 mas during a year, and this will be detectable. The distance l_{OS} to maser clouds such as Orion can be determined to ~20% accuracy from the proper motion of the many sources in the cloud[18]. Thus, if an individual moving source in a maser complex is lensed by a foreground star in our galaxy, or by a black hole in the galactic nucleus, the resulting velocity field of its images can be analysed to infer the mass and distance of the lens.

Extragalactic imaging provides a third illustration. It is widely thought that the engine powering extragalactic radio sources is a black hole with an accretion disk. There is also evidence for asymmetric nuclear radio jets which may exert a net thrust on the source causing it to behave like a massive rocket[19]. The resulting motion of the black hole may be inferred from the action of the moving lens on a suitably aligned background. Thus, if we view a source (a supernova or a hot spot in a radio jet, for example) that is behind an extragalactic object containing

a black hole of mass M, then the timescale for structural changes of the image of a background source is of order

$$\tau = \frac{\theta_0 l_{OD}}{v}$$

$$\approx (10{,}000)\left(\frac{M}{10^8\, M_\odot}\right)^{1/2}\left(\frac{l_{DS}}{l_{OS}}\right)^{1/2}\left(\frac{10^4\ \mathrm{km\ s^{-1}}}{v}\right)\ \mathrm{yr}$$

$$\approx 15\ \mathrm{yr} \qquad (18)$$

if $l_{DS} = 1$ kpc, $l_{OS} = 500$ Mpc, $M = 10^8\, M_\odot$ and $v = 10^4$ km s^{-1}. This might be observed on a reasonable timescale, especially if the source velocity is relativistic. □

T_c increased to 90 K in $YBa_2Cu_4O_8$ by Ca doping

T. Miyatake, S. Gotoh, N. Koshizuka & S. Tanaka

Superconductivity Research Laboratory, International Superconductivity Technology Center, 1-10-13 Shinonome, Koto-ku, Tokyo 135, Japan

THE two superconducting phases $YBa_2Cu_4O_8$ (124), containing double Cu–O chains, and $Y_2Ba_4Cu_7O_{15}$ (247), containing both single and double Cu–O chains, were originally discovered as lattice defects in the 90-K superconductor $YBa_2Cu_3O_7$ (123)[1]. The synthesis of bulk superconducting 124 may be effected by a high-oxygen-pressure annealing technique[2,3] and by reaction with ambient oxygen in the presence of alkali carbonates[4]. The oxygen stoichiometry of 124 is much more stable against high temperatures than that of 123 (ref. 2), a feature that is important for practical applications. But the lower T_c (80 K) of 124 presents a major obstacle to practical uses of this phase at liquid-nitrogen temperature (77 K). Here we report that partially substituting Ca for Y in 124 increases T_c. A superconducting transition of ~90 K was achieved for the composition $Y_{0.9}Ca_{0.1}Ba_2Cu_4O_8$.

We synthesized samples of $Y_{1-x}Ca_xBa_2Cu_4O_8$ ($x = 0$–0.1) using a high-oxygen-pressure technique. After mixing starting materials of Y_2O_3, $Ba(NO_3)_2$, CuO and $CaCO_3$, the samples were fired at 900 °C in flowing oxygen for 12 h, and then ground. The resulting powder was compacted into a rectangular shape at 100 MPa and then lightly sintered at 800 °C in an oxygen atmosphere. We repeated the hot isostatic pressing (100 MPa) in a gas environment of argon with 20% oxygen (oxygen-HIP) twice. The samples were first oxygen-HIP-treated at 950 °C for 6 h. At this stage, the X-ray diffraction patterns indicated that 124 was the major phase but broad diffraction peaks suggested a slightly disordered structure. The second oxygen-HIP treatment, at 1,050 °C for 3 h, yielded high-quality polycrystalline 124 with no secondary phases. The sample densities were 50–60% of the theoretical density.

Figure 1 shows the temperature dependence of the resistivity for $Y_{1-x}Ca_xBa_2Cu_4O_8$. These measurements were performed using a conventional four-probe technique. As the Ca substitution increased, the magnitude of resistivity decreased monotonically. This result indicates that the substitution of Ca^{2+} for Y^{3+} introduces holes into the 124 phase. All of the samples exhibited sharp superconducting transitions ($\Delta T_c = 3$–5 K), and the transition temperature increased with increasing Ca content x. For the sample having $x = 0.1$ the onset temperature of superconductivity was 90.9 K and the resistance reached zero at 87.4 K. There is a small 'foot' on the $x = 0.1$ resistivity curve, which may indicate weak links at the grain boundaries.

We measured Meissner signals (field cooling) and diamagnetic shielding (zero-field cooling) for powder samples with a SQUID (Quantum Design), in a magnetic field of 50 Oe. We estimate volume fractions of superconductivity for the samples

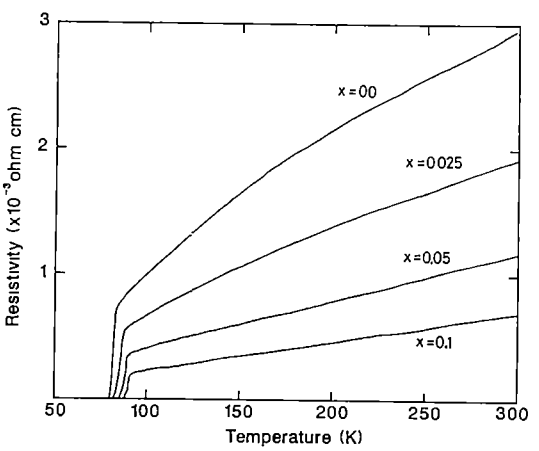

FIG. 1 Electrical resistivity of $Y_{1-x}Ca_xBa_2Cu_4O_8$ as a function of temperature. The zero-resistance temperature for samples with $x = 0.0$, 0.025, 0.05 and 0.1 are 79 6 K, 82.6 K, 84.3 K and 87 4 K, respectively

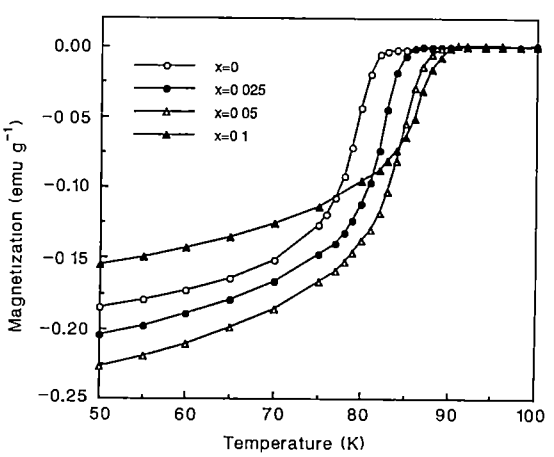

FIG 2 Temperature dependence of magnetization for powder samples of $Y_{1-x}Ca_xBa_2Cu_4O_8$ in a field of 50 Oe T_c from magnetization for samples with $x = 0$ 0, 0 025, 0 05 and 0 1 are 83 K, 86 K, 89 K and 91 K, respectively.

to be ~30–50% from the ratio of Meissner signal to diamagnetic shielding. The Meissner signals of samples with different Ca contents are shown in Fig. 2. Values of T_c determined from the Meissner signals are in good agreement with the onset temperatures derived from the resistance drop.

X-ray diffraction patterns for samples having $x = 0.1$, 0.05 and 0.0 are shown in Fig. 3. These patterns show that the samples have the orthorhombic structure proposed in ref. 5. As the Ca content increases, the c-axis lengthens slightly but the a- and b-axes remain more or less unchanged. The X-ray pattern for the sample with $x = 0.1$ includes a couple of impurity peaks with intensities <5% of the main peaks. The patterns for other samples, however, show no impurity peaks, indicating that these samples are single-phase 124. Although the superconducting transition temperature observed was >80 K, no traces of the 123 phase were present in the diffraction patterns. On the basis of the X-ray diffraction data and magnetization data (Fig. 2), the superconducting transition near 90 K must come from the Ca-substituted 124 phase.

Figure 4 shows that the thermogravimetric curves for samples with $x = 0$ and 0.1 are not significantly different. Neither sample decomposes below 800 °C. This result shows that the oxygen content of Ca-substituted 124, as well as 124 without Ca, has a high thermal stability up to a high temperature (~850 °C), and also that the 123 phase is absent in the samples. In addition, unlike 123, the materials are expected to have no orthorhombic–tetragonal phase transformation at an elevated temperature and no twin structures.

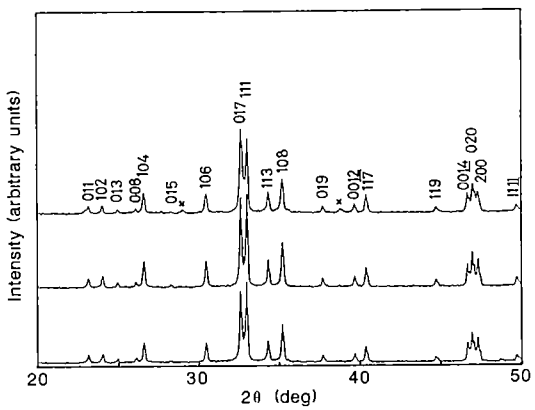

FIG 3 Powder X-ray diffraction patterns of $Y_{0.9}Ca_{0.1}Ba_2Cu_4O_8$, $Y_{0.95}Ca_{0.05}Ba_2Cu_4O_8$ and $YBa_2Cu_4O_8$ (top, middle and bottom curves respectively) Least-squares refinement of the crystallographic unit cells yielded a=3.842 Å, b=3 863 Å and c=27.19 Å for x=0.0, a= 3 841 Å, b=3 863 Å and c=27 21 Å for x=0 05, and a=3 841 Å, b= 3.864 Å and c=27.21 Å for x=0 1 Impurity peaks are marked with crosses No trace of $YBa_2Cu_3O_7$ is present

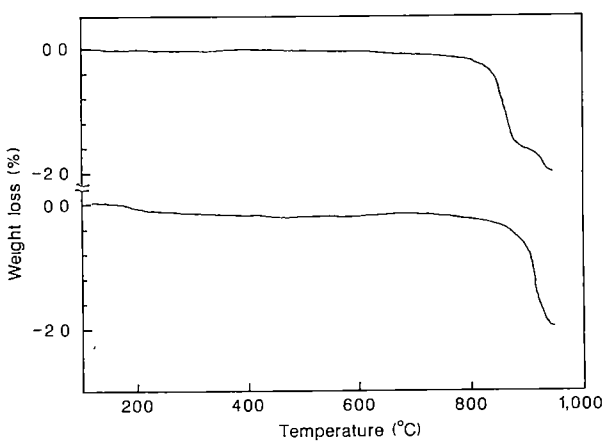

FIG. 4 Thermogravimetric curves of $Y_{1-x}Ca_xBa_2Cu_4O_8$. These measurements were carried out for samples with x=0.1 (upper curve) and 0 0 (lower curve) up to 950 °C and 800 °C, respectively The temperature was increased at a rate of 10 °C min^{-1}, in air

The 123 and 124 phases are the $n = 0$ and $n = 2$ members of a homologous series of compounds having formula $Y_2Ba_4Cu_{6+n}O_{14+n}$. The increase in T_c with Ca-doping can be explained using the average charge p per $[Cu\text{-}O]^{+p}$ unit cell proposed in ref. 6. The p that maximizes the T_c of 123 seems to be 0.33 (ref. 7) whereas for undoped 124 it is only 0.25. Therefore, if one assumes that 123 and 124 have similar electronic structures, the introduction of holes by Ca-doping the 124 would be expected to cause an increase in T_c to a maximum at $p = 0.33$. In practice, T_c seems to be optimized for a doping of around $x = 0.1$ rather than $x = 0.33$, perhaps because of a non-random distribution of holes.

The 90-K 124 superconductors have a good potential for technological applications because of the relatively large margin between T_c and liquid-nitrogen temperature and because of the thermal stability of the oxygen content. To study the origin of the enhancement of T_c, synthesis of samples that are highly doped with Ca and other elements are in progress. □

The pine needle as a monitor of atmospheric pollution

G. Eriksson, S. Jensen, H. Kylin & W. Strachan*

Department of Environmental Chemistry, Wallenberg Laboratory, University of Stockholm, S-10691 Stockholm, Sweden

THE concentrations of toxic chemicals in the atmosphere and their deposition and long-range transport are becoming one of the more prominent issues in environmental chemistry. In 1986, a report[1] was published documenting the levels of DDT (p,p'-dichlorodiphenyl-trichloroethane) and other organochlorine contaminants in the muscle tissue of pike and herring from areas in and around Sweden. There has previously been a downward trend in residue levels but in parts of Sweden and the south Baltic during 1983–84, the ratio of p,p'-DDT to its metabolites significantly increased, indicative of freshly released DDT from a source south of Sweden. (DDT has been restricted or banned in most of Europe since the 1970s.) It was established[2] that an increased forest spraying program using DDT was implemented in 1984 in the southern part of East Germany. DDT can be transported over very long distances[3] and in light of the above there is a need for an extensive field programme to monitor such pollution and locate its source. Here we test the hypothesis that the pine needle is a suitable monitoring matrix and delineate the extent of the DDT contamination of 1983–84. We conclude that the pine needle is a suitable monitor of atmospheric pollution and that because of the widespread distribution of the pine, it may provide time-series data for much of the Northern Hemisphere from which trends in atmospheric pollution may be discerned.

DDT and other similarly transported, persistent contaminants partition themselves between the vapour state and inert

‡ Samples from Poland were obtained for 1987; needles were not available for 1984 At one of the two West Poland sites the samples collected were from *P. mugo*.

lipophilic materials[4,5]. Pine needles provide such a matrix as they are covered with a wax coating which, on the whole, is similar for different locales and years[6] and has been shown to contain a number of atmospherically transported pollutants[7–9]. Furthermore, it is easy to identify the needles from three or more years and so collect data for several years in a single sampling. Contact with rainwater and absorption of the dissolved material by the needles is likely to be slight[10]; dryfall particulate matter, although observed on needle surfaces, is believed to provide only a minor part of the contaminant burden of the needle wax. Translocation of the investigated compounds from the soil through the roots has been found to be a minor source of leaf residues in other plants[10,11] but the significance of this route is not established for the pine. Diffusion within the wax layer[12] is expected to be very slow because of the highly impermeable nature of the wax subsequent to emergence. Although background concentrations of the study compounds arising from global pollution are expected to be found in the needle wax, it should also show elevated levels when releases occur locally over a sufficient period to allow absorption. We consider these conclusions, although unproven in some instances, to be reasonable and conclude that contaminant concentrations in the needle wax will largely reflect time-integrated air concentrations. Indeed, meteorological effects aside, knowledge of these concentrations and the partition coefficients for wax/air, could provide a semi-quantitative estimate of the mean air concentrations.

To test the hypothesis that the pine needle is a suitable monitoring matrix and to determine the extent of the DDT event(s) of 1983–84, we analysed samples that had been collected during the period July–September 1986. These samples were collected along a transect running from the south-west to the north-east of western Europe (see Fig. 1), the direction of the prevailing winds in most of the study area. The sample trees were selected to reflect rural and remote rather than urban or industrial conditions—the trees were 20 km or more from major urban centres and situated with open areas to their south-west; they were remote from any major highways and were sampled at 2–5 m above the ground on the south-west face of the trees. The wax coating of the needles was extracted twice with dichloromethane, treated with diazomethane, cleaned on a sulphuric-acid-containing silical-gel column and analysed using a capillary gas chromatograph with an electron-capture detector. Each sample year was analysed separately for DDT and DDE (p,p′-dichlorodiphenyl-dichloroethene), PCP (pentachlorophenol) (methylated), total PCBs (polychlorinated biphenyls) and α-HCH (hexachloroclohexane) and lindane (the γ-HCH isomer) for each of the 44 sample sites. Mean levels for several geographic areas grouped roughly by distance from the suspect source area are presented in Table 1. The average relative standard deviations (r.s.d.) for the group means were: 40% for tDDT, 62% for PCP, 26% for PCB and 68% for tHCH. The years designated are those of needle growth, which is generally complete by July of the year of emergence of the needle; the needles designated 1986, 1985 and 1984 had been exposed to the atmosphere for 3–6 months, 1.5 yr and 2.5 yr, respectively, before they were collected.

The total DDT residue (tDDT) data in particular demonstrate the utility of pine-needle wax as a monitor for events such as those that are believed to have occurred in 1983–84 in the forests of East Germany. Elevated levels of 3–4 times the 'background' (the lowest means of 0 2–0.3 ng g^{-1}) were observed at Herzberg and Hamburg, sample sites closest to the presumed source, and the 1984 area of impact stretched from southern France to the coastal region of Sweden north of Stockholm—a distance of over 1,500 km. In 1985, high levels persisted in Switzerland,

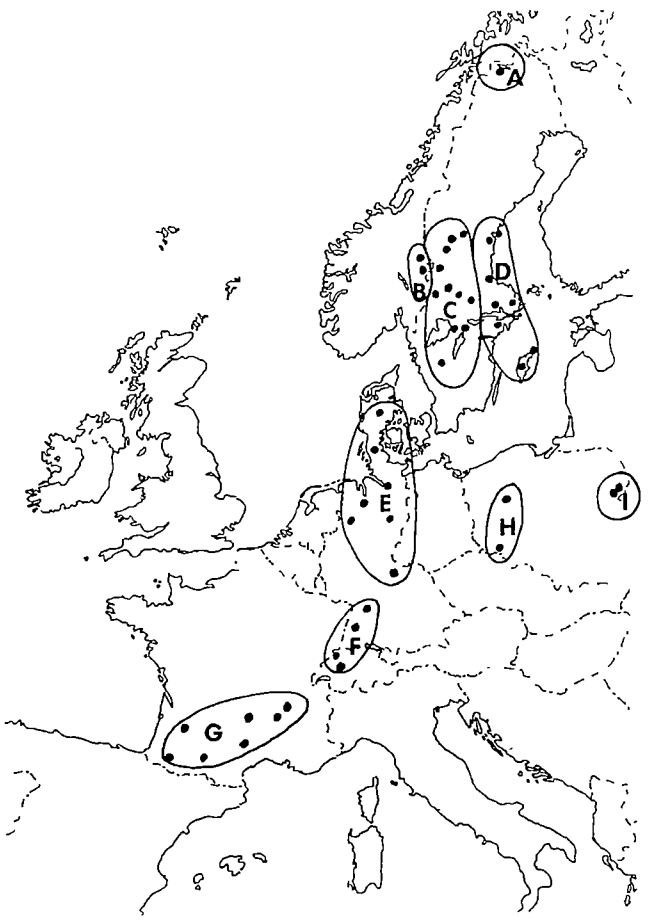

FIG 1 Pine-needle sampling stations for the 1986 collections

Germany and Denmark although the zone of impact was about half that of the previous year. Samples from western Poland became available in 1987 and needles from 1985 showed even higher levels there (8–10 times the 'background') than elsewhere that year. By 1986, concentrations in nearly all regions were at the background level but samples from western Poland were still 6–8 times this level. These results are illustrated in a bar graph (Fig. 2).

We did not find the expected cumulative increased in tDDT residues in needle wax from 1986 to 1984. This could have been the result of photodegradation of the pesticide (to a substance other than DDE)[13,14] in the needle wax, to translocation into the interior of the needle or the rest of the tree[15], to re-volatilization, or to lack of sorption at times other than during needle growth. Degradation seems not to be indicated because the percentage of DDT was constant (mean 68%, r.s.d. 13%) throughout the study area and period and such a high DDT/DDE ratio is indicative of freshly applied DDT. Re-volatilization of the study compounds is not indicated[16] either.

In the case of the PCP results, the Swedish samples were found to contain at least twice the levels found elsewhere in Europe. This observation includes a site in the far north of Sweden where we expected levels of pollution to be lower. This overall observation for PCP is surprising because the compound has been totally banned in Sweden since 1978 (partially since 1972) although it is still in use in much of the rest of Europe including Finland. Use in the latter country could potentially contribute to the Swedish burden but the prevailing winds do not favour this. As there are no apparent changes in concentration levels over the years, we conclude that the source is still present.

The PCBs are well known pollutants in the atmosphere and elsewhere and were found in all the samples at roughly the same concentration levels (mean 6.2 ng g^{-1}, r.s.d. 26%). There were no apparent geographic or temporal trends. The HCH isomers are also well-known ubiquitous atmospheric pollutants and, as in the case of PCBs, we observe no patterns in their needle-wax concentrations. Examination of the proportion of the γ-HCH isomer (the pesticide lindane) shows that it is present in larger amounts in the French samples (mean 62%, r.s.d. 14%, 11 points) during 1985 and 1986 than elsewhere (mean 29%, r.s.d. 11%, 34 points), indicating a near-by source. As observed with tDDT residues, the ratio becomes 'normal' with increased distance and time from the apparent source.

It seems that the pine needle can provide a suitable sampling matrix for evaluating atmospheric contaminants. This seems particularly true when determining regional exposures from a single-year class and may also have relevance for trend analysis between years. The widespread distribution of the pine suggests that it may provide trend data for much of the Northern Hemisphere. In Eurasia, *Pinus sylvestris* (Scots pine), is found in most areas north of the Mediterranean and south of the Arctic circle[17]. In North America, the Scots pine is an imported species but is sufficiently common that it may have utility there as an environmental biomonitor. The species *P. banksiana* (Jack pine) and *P. contorta* (Lodgepole pine), however, may be more useful for evaluating ambient conditions east and west of the Rocky Mountains, respectively. The long life of the pine, compared with other biomonitors, potentially permits sampling from the same individual over periods as long as one hundred years. □

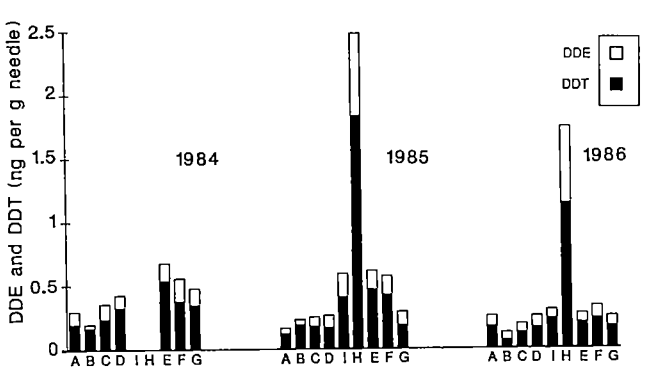

FIG. 2 Distribution of DDT and DDE in pine needles (fresh weight) (see Fig 1 for area designations; samples were not available for areas H and I in 1984).

Atmospheric circulation during Holocene lake stands in the Mojave Desert: evidence of regional climate change

Yehouda Enzel*, Daniel R. Cayan†, Roger Y. Anderson* & Stephen G. Wells*

IT is commonly thought that the climate conditions that supported lakes over a period of years in the Mojave Desert in southern California, only existed before 8,000 yr BP and that the environment has been arid since[1,2]. Here we look at a drill core in the Silver Lake playa at the terminus of the Mojave River and find Holocene lake deposits which indicate that shallow lakes existed for at least a few decades. These deposits were radiocarbon dated at 3620±70 and 390±90 yr BP, corresponding to the early Neoglacial and the 'little ice age' respectively[3]. To identify the conditions necessary to produce these Holocene lake events we have examined the modern climate and hydrological patterns that produce ephemeral lakes in this usually arid watershed. Available data indicate that there is a link between anomalous winter atmospheric conditions over the North Pacific and Mojave River floods that produced ephemeral lakes in the Silver Lake playa and that the Mojave River filters out small to medium floods and allows only the extreme floods to reach the terminal playa and leave a record of the anomalous conditions. We suggest that the late Holocene lakes may have resulted from persistent similar atmospheric circulation patterns and winter floods.

The Silver Lake playa is the remnant of the late Pleistocene Lake Mojave[3–6] and the present terminal basin of the closed arid watershed of the Mojave River. At 9,500 km^2 (Fig. 1) this watershed is the largest hydrological system in the Mojave

Desert. Present climate within the Mojave River watershed varies spatially. Its headwaters at 1,200–2,700 m in the eastern slopes of the San Bernardino Mountains (Fig. 1), are characterized by Mediterranean semi-arid to humid conditions (mean annual precipitation 500–1,250 mm), with most of the precipitation occurring between November and March. Most of the Mojave River watershed and the terminal playa region where the lakes form is hyperarid, with <100 mm year^{-1} precipitation, summer temperature often >40 °C and consequently >2000 mm year^{-1} potential evaporation[7,8].

The Mojave River flow is a result of intensive winter storms at the high elevations of the San Bernardino Mountains[8,9]. Annual discharge records (Fig. 2)[10] along the Mojave River demonstrate that significant flow reaches the Afton gauging station only during those years with large discharge at The Forks in the Mojave River headwaters (Fig. 1). This is due to discharge loss to a shallow aquifer between Victorville and Afton. Hydrographs of the 1969 and 1978 winters events (Fig. 2) are characteristic of an extreme winter flood which, in turn, is related to the annual peak discharge (Y.E., Thesis in preparation). During such winter events lakes formed in Cronese Lake and the Silver Lake playas. It seems that only flood events with high peak discharge are able to exceed the loss by infiltration into the alluvial bed between Victorville and Afton (Figs 1, 2). This relation and the annual peak-discharge data[10] indicate that discharge losses along the Mojave River allow only the larger floods to reach Afton. During this century a peak discharge >300 m^3 s^{-1} at the Fork has been required for flows to reach Afton and ~ 500 m^3 s^{-1} to reach the Silver Lake playa (Fig. 1).

We suggest that similar filtering of smaller floods occurred in the past, at least in the late Holocene. The modern conditions suggest that increased frequency of flows exceeding this natural threshold are needed and may have led to a net accumulation of water in the playas during the late Holocene.

Since 1894, eight ephemeral lakes have been documented in the terminal basins of the Mojave River (Y.E., unpublished data). Each ephemeral lake is the result of heavy precipitation during a winter storm and flooding in the Mojave River headwaters. Rainfall in several of these storms exceeded the average monthly precipitation by two standard deviations[11]. Extreme rainfall intensity of over 25 mm h^{-1}, and as much as 250–400 mm day^{-1}, has been observed[12] in the Mojave River headwaters at elevations >1750 m. These high precipitation intensities were probably enhanced by the orographic effects of strong southerly to southwesterly winds forcing a moist Pacific air mass to cross the north-west to south-east oriented San Bernardino Mountains[13].

The eight lake stands that were produced from these storms occupied the normally dry playa for 2–18 months (Y.E., thesis in preparation). In some of these events antecedent conditions of soil moisture in the headwaters and a wet channel along the Mojave River may have played a role as relatively large floods in the headwaters predated some of the lake-building flood events[3].

To overcome the filtering mechanism of the river and to form a lake in its watershed requires a vigorous storm, unusual for southern California. We constructed the mean meteorological pattern associated with these storms and lakes. Composite monthly sea-level pressure (SLP) values (which we use because of their availability over a Northern Hemisphere grid since 1899[14]) and the SLP anomalies over the North Pacific and western North America were calculated for the months that included the eight cases of lake events (Fig. 3). The SLP values for each month in which a lake event occurred were subtracted from the long-term mean SLP (1947–1972)[15] of the specific month to determine the monthly SLP anomaly. Although the actual flooding occurred on specific days with more intense SLP features than the monthly mean, several of the flooding events were associated with a persistent succession of storms that conformed to a particular pattern. The monthly SLP patterns provide an overall indication of the large-scale pattern that produced the particular storm or storm sequence.

During months in which lakes formed, the sub-tropical high in the eastern North Pacific weakened, giving way to an anomalously low-pressure system along the west coast of the United States. The anomalous low represents an eastward shift of the central North Pacific winter low, with vigorous storms penetrating the west coast of the United States much further south than normal. These storms produced the heavy precipitation in the San Bernardino Mountains.

The composite SLP pattern (Fig. 3) shows a tendency for a 'split' Aleutian low with higher than normal SLP in the Aleutians and an anomalously low SLP over Kamchatka. The blocking high pressure in the eastern Aleutian region during this type of

The shaded area shows where discharge loss occurs between Victorville and Afton. Logarithmic scales are used for both discharge and precipitation

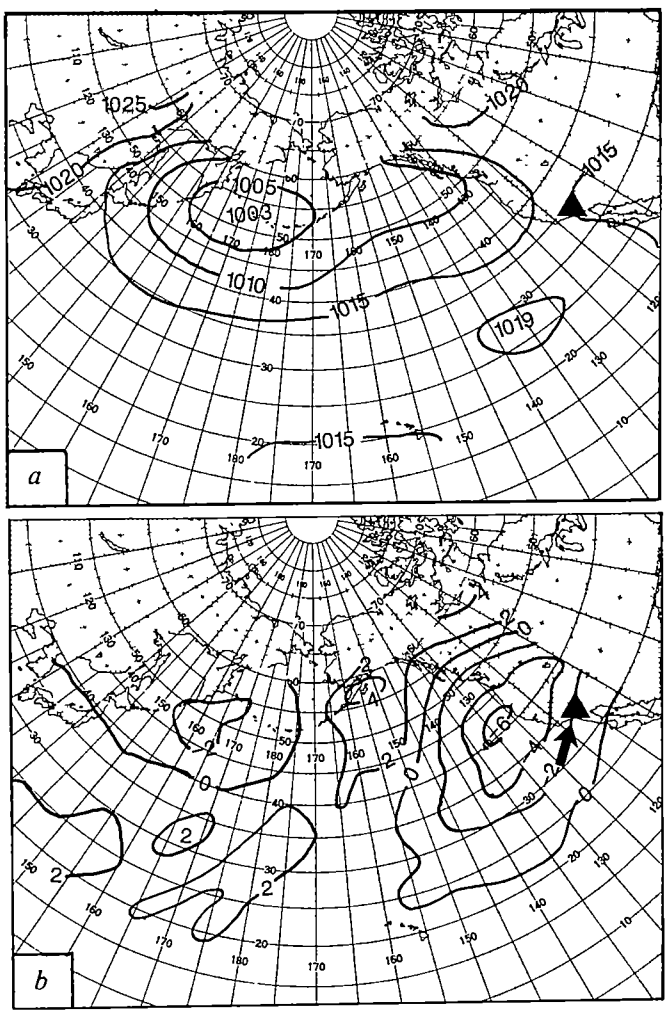

FIG. 3 *a*, Composite North Pacific sea-level pressure for the eight months with lake-building flood events. Triangle indicates location of the San Bernardino Mountains *b*, Composite SLP anomaly for the same eight months. The arrow shows the anomalous component to the mean wind direction that results from the anomalous SLP. The enhanced southwesterly wind advects moist warm Pacific air over the San Bernardino Mountains and the negative pressure anomalies indicate the necessary vorticity for extreme precipitation events

event is also borne out by inspection of daily maps. This synoptic pattern has been diagnosed as a potent flood-producing condition in California[13]. The Mojave River flood and lake events are symptoms of this pattern.

The strong negative anomaly of −6 mbar at 40° N, 130° W (Fig. 3) represents 1.5–3.0 standard deviations from the long-term monthly mean (depending on the specific winter month in which the flood occurred). Other studies of winter and monthly average precipitation and stream flow have shown this condition to favour heavy precipitation and stream flow in California[16–18].

Individual 500-mbar and 700-mbar height maps, satellite images, and previous studies[17,19] for the winter and the months of the floods in 1969, 1978, 1980 and 1983 floods, reveal two recurrent synoptic patterns. The most frequent pattern featured an unusually deep trough or cut-off low pressure offshore from California and a blocking high pressure in the Gulf of Alaska with a southerly displaced storm track entering California. In some of these cases, such as the 1969 storm[20], moisture and strong winds of these storms were assisted by the activity of the sub-tropical jet stream. A second pattern that emerged, was a sequence of storms embedded in strong southerly-displaced westerlies that spanned the entire eastern North Pacific. This pattern occurred during the 1980 and 1983 events.

There is evidence[21] that ocean surface boundary conditions may have played a role in the development of these storms. Highly persistent patterns of sea-surface-temperature (SST) anomalies were found in the North Pacific during the winters of 1969, 1978 and 1980, in which lakes were formed. Although probably not a necessary condition, such winter-SST-anomaly patterns may increase the frequency of extreme storm episodes.

Water-budget calculations suggest that an order of magnitude increase in the modern average annual discharge at Afton Canyon (from 9.4×10^6 m^3 to 90×10^6 m^3) is required to maintain a lake in the terminal playas. Water volumes similar to the latter discharge have been measured during the short-term extreme historical floods. Decreasing evaporation alone will not maintain a lake without the large runoff increase[3]. Because the extreme floods are relatively rare (recurrence intervals of 34 years in Afton), the modern average annual river discharge is not representative of the actual volumes that can reach the playas during the large floods. If the volumes of the modern extreme floods are used as the total annual input over a series of years in the lake's hydrological budget calculations, a lake can be established in Silver Lake[3]. An increase in the frequency of flood events with magnitudes similar to the modern largest floods would therefore result in a perennial lake in the Silver Lake playa. This may have caused the formation of the late Holocene lakes.

Analyses of tree-ring data from southern and central California[22,23] indicate that more-frequent wet conditions occurred in

the late 1500s and early 1600s at the same time that the 'little ice age' lake was maintained in Silver Lake basin[23]. The high-frequency, high-magnitude annual precipitation and stream flows that have been inferred for that period in southern California[22,23], support our suggestion of increased frequency of the high-magnitude precipitation and runoff events during the 'little ice age' lake stand. As the lake-building storms of the past century were all vigorous eastern North Pacific cyclones that occurred during the winter, we postulate that similar North Pacific disturbances were more frequent during the late 1500s and early 1600s. Reconstructions of North Pacific SLP from tree-ring chronologies[24] showed that the early 1600s to have had a high frequency of the pattern of North Pacific SLPs similar to the SLP pattern of the wet lake-forming winter of 1978. LaMarche[25] suggested that persistent 'little ice age' and earlier climate anomalies can be explained by changes in the frequency of anomalous circulation types. One of these types was characterized by upper-level trough centred over the Pacific Coast of North America.

We suggest that extreme modern hydrological events in the Mojave River watershed serve as an indicator of particular atmospheric forcing patterns over the North Pacific and thus can be used as analogues for conditions during the Holocene when lakes formed in the watershed. An increased frequency of these extreme events can explain the observed lake deposits in the Silver Lake playa. □

Storm wave reactivation of a submarine landslide

SUBMARINE landslides move large amounts of sediment and are often hazardous to offshore installations. Marine surveying techniques effectively define landslide locations and geometries (for example, refs 1–4) in various underwater geological settings, including deltas, fjords and earthquake-prone areas[1–5]. Movement rates and mechanics are generally inferred from indirect evidence, such as cable breaks and damage to sea-floor structures (for example, refs 6–8) but actual measurements of landslide behaviour are sparse. Using bottom-deployed pressure sensors, tiltmeters and accelerometers, we have collected data on sea-floor landslide reactivation involving sediment collapse and remoulding on the submarine slopes of the Huanghe delta, China. The sensors were emplaced into sea-floor clayey silts on 4 October 1987 and recovered on 16 October after the passage of three severe storms.

The Huanghe delta provides an ideal natural laboratory for the measurement of depositional and post-depositional deformations[3,9] of the sea floor. The delta has very high deposition rate[10] and the delta front is subjected to storm waves. Further, the shallow water facilitates the deployment of instruments.

Post-depositional slope failure creates collapse depressions and silt flows on the underwater Huanghe delta in water depths of 4–15 m and over gradients of 0.3–0.4° (Figs 2, 3). Roughly circular collapse depressions (0.5–1.0 m depth) occur mainly on

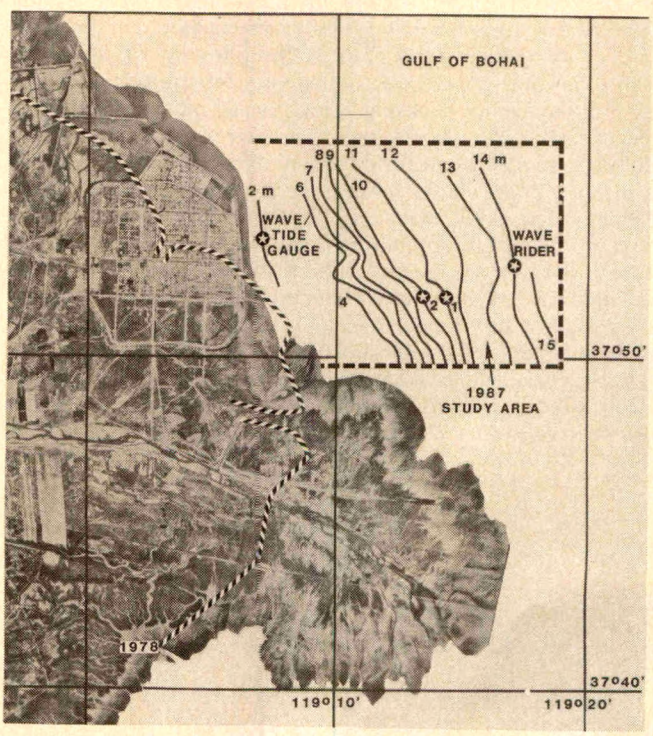

FIG. 1 Location of *in situ* measurement on the north-east flank of the Huanghe delta. Shoreline position is the 1987 position; former (1978) shoreline is outlined.

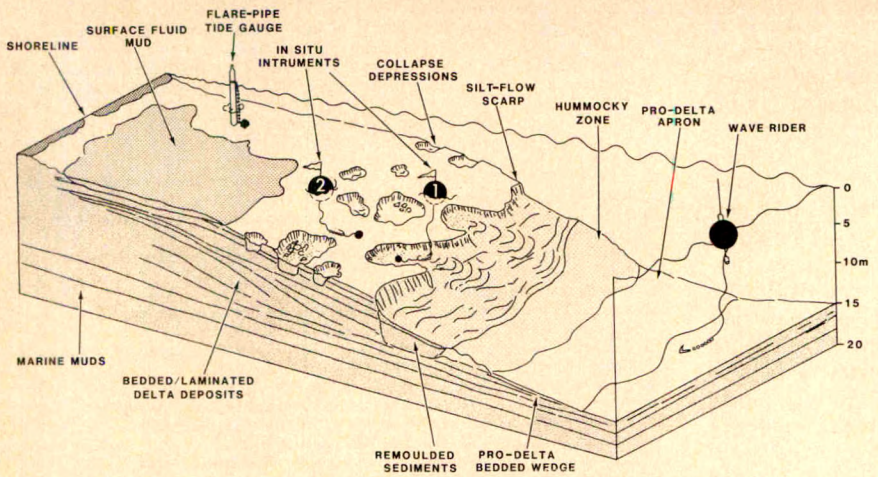

FIG. 2 Schematic representation of instability features on the northeast-facing slopes of the Huanghe delta and the deployment of instruments.

the upper delta in water 4–8 m deep. Between 9- and 11-m water depth, numerous finger gullies 100–500 m wide lead downslope towards a pronounced silt-flow scarp. This scarp is 1–2 m high and bounds the upslope edge of a highly deformed area, extending around the delta front in water depths of 11–14 m. Farther downslope blocky, 'ropey' areas of remoulded sediments are widespread. The collapse depressions and silt-flows are acoustically transparent, remoulded sediment areas on 3.5-kHz profiles, as compared to parallel bedding in neighbouring undisturbed areas.

The bottom features and sediment geometries were previously ascribed to liquefaction of rapidly deposited silts under the influence of storm-wave-induced bottom stresses[3]. To test these concepts and obtain *in situ* data on deformational processes, we deployed instruments along an offshore–onshore transect at the beginning of the autumn storm season (Figs 1, 2). Our approach was to measure waves entering from the maximum fetch while simultaneously monitoring bottom response inside and outside areas showing deformation. An inshore wave–tide pressure gauge was attached to an oil-field flare pipe in a water depth of 2 m. An offshore wave-rider was anchored in the lower delta in 14-m water depth (Figs 1, 2). Following 100-kHz side-scan sonar and 3.5-kHz profiler surveys for site selection, two sediment-dynamics packages were inserted into the uppermost 1 m of sediment. One package was located within a silt-flow gully (1 in Fig. 2), where the thickness of the remoulded sediment to the base of the silt flow was 3.8 m in a water depth of 11.0 m. The sediment texture from coring within the silt flow was 62.3% silt and 37.4% clay. Another package was placed 1-km upslope from the first package in an area of undisturbed sea floor underlain by 6–7 m of parallel-bedded delta-front sediments in a water depth of 9.5 m (2 in Fig. 2). The sediment texture from a core averaged 49.4% silt and 50.5% clay.

Each instrument package contained a compass, a three-axis accelerometer, sensors for x and y tilt, and water column and pore-water pressure sensors. The water-column pressure-sensor port was located at the top of the package, whereas the pore-water porous tip was at a depth of ~1 m below the mudline. The packages were designed to record accelerations and water-column pressures at a 1-s sampling interval over a 15-min period every 3 h. Eight sequential readings of tilt, compass and pore-water pressure at 1-s intervals were also made every 3 h. The specific gravity of the packages was 3.7, or about twice the density of the sea-floor sediments.

Three severe autumn storms occurred between 5 and 15 October, with winds from the north and northeast at sustained speeds ranging from 15 to 25 m sec^{-1}. Our research vessel, the *Huanghe 86*, sheltered inshore, close to the flare pipe, on 6 and 7 October, and also continuously from the evening of the 11 October until early on 16 October. A larger vessel, RV *Dong Fang Hong*, anchored offshore from the delta in water depths of 11–15 m, making visual observations of wave conditions in support of wave-rider records.

During the storms significant wave heights at the wave rider reached 2.5 m, with a period of 8.2 s. The first storm occurred on 6–7 October and was followed four days later by two more closely spaced storms (Fig. 4a).

Wave energy was dramatically attenuated across the delta front in all three storms. For example, the significant heights at the wave rider and inshore flare pipe for 12 and 14 October were 2.1 and 0.6 m, and 2.5 and 0.8 m, respectively. Wave periods diminished from 8.2 s offshore to 7.1 s inshore. In general, there was an observed 80% reduction in wave energy across the delta front.

The instrument package in the featureless, undisturbed area (2 in Fig. 2) remained virtually stationary during all three storms, except for some very low amplitude (~1 cm) oscillatory motion (periods 6–8 s) of sediments in response to cyclic loading by the waves. Comparison of side-scan sonar records made before and after the storms confirmed that the featureless area at location 2 remained unchanged.

In contrast, the sensors in package 1 revealed three distinct

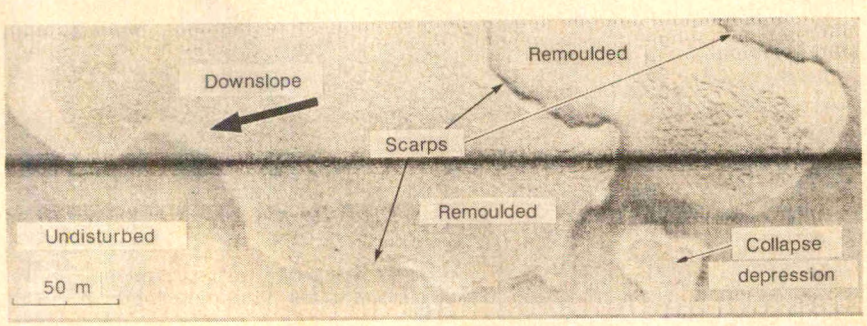

FIG. 3 Side-scan sonar swath illustrating typical silt flow and collapse-instability features on the Huanghe delta front.

periods of bottom sediment motion (Fig. 4*c–e*) because of reactivation of the silt flow during the storms. The instrument package underwent several types of motion. For example, the difference between bottom pressure signals from packages 1 and 2 (Fig. 4*c*) indicates the sinking of package 1 into the bottom. On 5 October, upon deployment, package 1 experienced initial settling. The package sank farther over a period of ~6 h on 6 October and larger displacements followed on 11–12 and 14–15 October. Accompanying these sinking movements were three discrete tilting events, beginning on 6 October for ~15 h, on 11–12 October lasting 27 h and on 14–15 October for 21 h. During these storms the package sank >1 m into the mud and tilted a total of 150° (Fig. 4*d*). The beginning of each package motion event coincided with increasing wave energy (Fig. 4*a*, *c*, *d*). The initiation of movement coincided with wave-bottom pressures at packages 1 of 4.5 kPa on 6 October, 6.5 kPa on 11 October and 9.3 kPa on 14 October. Motion ceased toward the end of each storm when wave-bottom pressures dropped to less than 2–3 kPa (Fig. 4*a*).

The details of pore-water pressure changes, recorded by the sinking and tilting package, are complex. Tidal variations of pore pressure were detected, along with mean changes. To extract the mean changes (Fig. 4*b*) from the total record, the mean bottom pressure signal was subtracted from the pore-pressure signal in package 1. During the first storm, the relative pore-water pressure increased late on 6 October and then decreased early on 7 October. Another relative pore-water pressure rise began on 10 October, before the arrival of the next storm. The pressure then declined throughout that storm and remained negative, declining irregularly until the package was retrieved. Because of the movement of the package, any reliable correlation between pore-water pressure, movement and storm activity was lost. After the first movement event, when pore-water pressure increased initially and then dropped as movement began, the pore-pressure data are erratic and are not considered accurate.

Vertical oscillations of the near-surface sediments and the instrument package also occurred during the first two storms (Fig. 4*e*). By the third storm, the highly tilted attitude precluded further reliable measurements of the oscillations. During the first storm, bottom motion was detected 3 h before the tilting and sinking were initiated and it occurred simultaneously with the increase in pore pressure (hour 18 on 6 October). The bottom motions reached maximum amplitude at 0300 and 0600 on 7 October, 3 and 6 h after the peak in the bottom pressure was reached.

Although the packages showed oscillatory and vertical motion, actual cumulative horizontal transport was not determined owing to limitations in navigation accuracy. Comparison of sonar coverage of surface silt flows before 6 October and after 15 October showed local roughening, but the overall outlines of the silt flows were unchanged after the three storms.

The data clearly show that existing landslide features experienced renewed and repeated movement without enlargement or upslope retrogression. These observations contradict the concept that failed areas should be more stable because of reduced slope, dewatering and consolidation. Similar evidence for activity of existing collapse features was acquired from the Mississippi delta front, in which wave and pore-pressure sensors foundered within the sediment[11].

The Huanghe delta data also show that existing landslide features are more susceptible to renewed movement than surrounding undisturbed areas. First-time slope failure apparently requires greater applied stresses than are necessary to reactivate already failed areas, at least within the stress ranges measured during the experiment. Perhaps the very small differences in sediment properties at site 1 and site 2 (for example, 10–15% contrasts in clay and silt contents) are sufficient to account for the different behaviour.

The data show that landslide reactivation movement was not

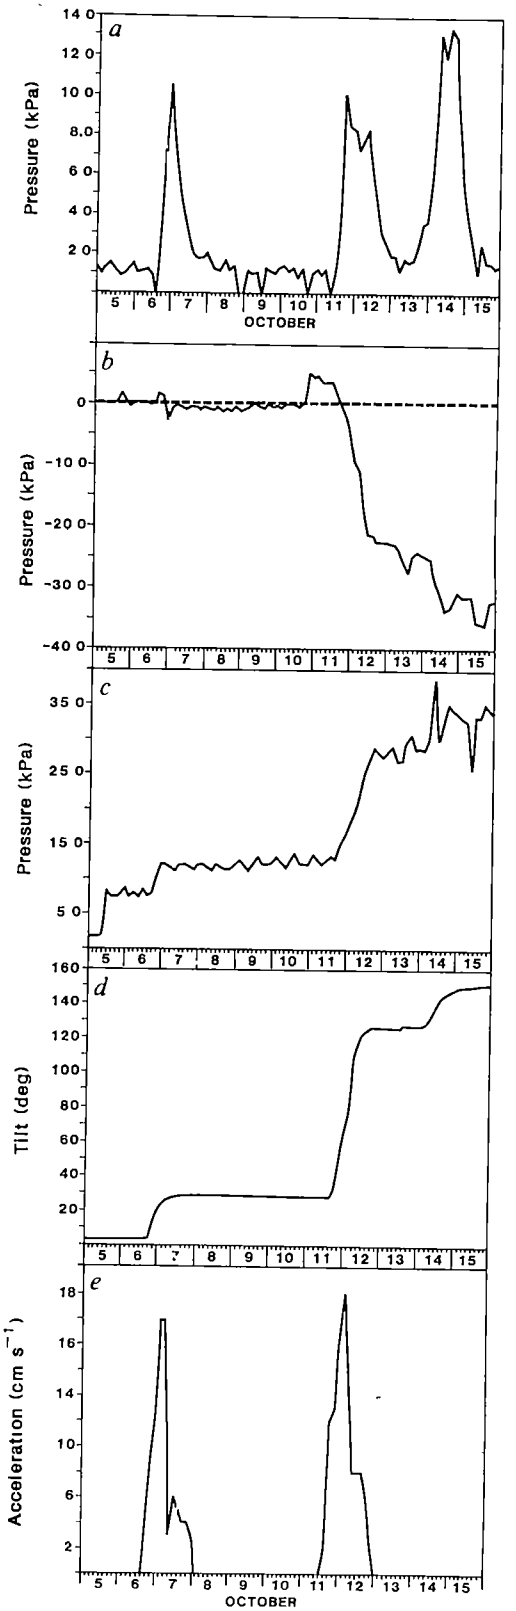

FIG. 4 *In situ* data showing *a*, wave-bottom pressure from site 2 and time-series measurements of *b*, pore-water pressure *c*, residual bottom pressure *d*, tilt (*y*-axis) and *e*, wave-induced bottom accelerations (*z*-axis) within silt-flow feature at site 1. Wave data (*a*) is maximum amplitude during a 3-h period

abrupt and catastrophic, but gentle and gradual occurring over many hours. This behaviour is in strict contrast to that inferred from cable-break data in other documented cases of first-time failures (for example, refs 6, 7).

The measured attenuation of wave energy exceeds that which would be predicted from conventional wave theory. Because there is little motion of the bed in undisturbed areas of the delta front, we conclude that the energy sink is in the oscillatory motion of sediments in the collapsed areas. A similar pattern of wave attenuation across the Mississippi-delta mudslide region has been recognized[12].

Each reactivation event involved loss of bearing capacity of the sediment within the feature, permitting the negatively buoyant package to sink. At the end of each wave-loading period, sinking ceased, suggesting some regain in bearing strength. This behaviour might be interpreted as a type of liquefaction in which the sediment progressively becomes more dense, but then the amount of reactivation would be expected to decline. Laboratory analyses of time-dependent strength changes on samples taken from inside the feature at site 1 show thixotropic characteristics. Undrained strengths, from fall-cone tests on remoulded sediments increased by 90% within 30 h, with no change in water content. Subsequent remouldings of the sample repeated the pattern of dramatic strength loss and regain. □

Submarine magma degassing and explosive magmatism at Macdonald (Tamarii) seamount

K. H. Rubin & J. D. Macdougall

Geological Research Division, A-020, Scripps Institution of Oceanography, La Jolla, California 92093, USA

MACDONALD seamount is an active volcanic centre located at 29°98′ S, 140°25′ W in the south-central Pacific. Since its discovery[1] in 1968, a number of expeditions have surveyed and dredged rocks from the seamount. During a Scripps Institution of Oceanography expedition in October 1987, the first direct observation of volcanic activity at Macdonald was made when a small eruption occurred spewing forth scoriaceous basaltic rocks which briefly floated to the sea surface. The rocks were accompanied by huge bubbles of volcanic gas that created large sea surface slicks (H. Craig, personal communication). Similar activity at Macdonald was observed by a joint French–German team in January 1989 using the submersible *Cyana*[2]. Here we look at the radiogeochemical features of the lone rock recovered from the October 1987 eruption. We present analyses of U-series nuclides from the first observed eruption of Macdonald (also known as Tamarii) seamount with interpretations focusing on the timescales of magmatic events and the implications of uranium-series data for magma degassing. This highly gas-charged magma lost all of its volatile ^{210}Po upon eruption. Based on this, estimates of the fluxes of other volatile elements to sea water, which may contribute significantly to their oceanic budget, are calculated. High (^{230}Th/^{232}Th) and ^{87}Sr/^{86}Sr ratios, common signatures of altered crust, suggest that the explosive nature of the Macdonald volcanism results partly from the sealing of magma conduits by seawater circulation.

Macdonald seamount sits on Eocene age Pacific lithosphere[3]. Based on a regression of ages for the Austral–Cook islands, Macdonald seems to be the current active site of that linear hotspot chain[4,5]. The volcano rises ~1,800 m from the sea floor and has a small summit plateau (100 m × 150 m) about 40 m below sea level (b.s.l.) with one 50 m × 30 m pinnacle at 27 m b.s.l.[6]. In 1983, scuba divers identified a rift on the summit plateau consisting of fresh walls with small (6-m-high) spatter cones of scoriaceous lava on either side[6]. Although no volcanic activity had been observed directly, the summit had apparently enlarged in the eight years since previous surveys[7], adding some 20 m to the pinnacle[6].

Macdonald seamount was originally discovered as a source of teleseismic (T) waves associated with gas bubbles bursting in the water column during eruption of the volcano[1]. T-wave records registered by the Polynesian seismic network provide a detailed record of eruptions since 1968[2,6]. From 1968 until 1977, the volcano was quiescent. A ten-year period with 1–24 days of activity per year followed. In mid-1987, the volcano entered a very active phase and, since then, has been erupting about 50% of the time The T-wave record shows that more than half the eruptions start with explosive outbursts. This is in contrast to the less strombolian eruptive style usually inferred for submarine volcanism.

The rock sample recovered from the 11 October 1987 eruption, which floated to the surface and was still warm when collected, is a scoriaceous alkali basalt measuring about 30 × 15 × 15 cm. It contains 40–50% vesicles by volume in a glassy matrix. Trace amounts of very small (0.1 mm) unzoned plagioclase (An_{85}) and olivine (Fo_{65}) phenocrysts are present. The glass composition, determined by electron microprobe analysis, is 44.5% SiO_2, 4.48% TiO_2, 5.4% MgO and 5.38% $Na_2O + K_2O$. Previous expeditions have recovered mostly alkali-olivine basalts of similar composition and gabbros from the summit and flanks of the seamount, suggesting that the shield-building stage is essentially over (ref. 8 and M. Seguin *et al.*, unpublished data). Compositions of these rocks indicate that their parental magmas experienced fractionation in a crustal magma chamber, which has been identified with magnetic surveys[7].

The activities of all ^{238}U-series nuclides are equal in a closed system, a state known as secular equilibrium. Disequilibrium between any pair of these nuclides in an erupted lava gives direct information about the timescale and extent of chemical fractionation during the magma lifetime. This is because the nuclides are distinct chemical species that can be separated from each other by fractionation and because secular equilibrium is re-established according to the half-life of the daughter nuclide. In general, disequilibrium is distinguishable from secular equilibrium over a period of ~5 half-lives of the daughter isotope. Following convention, we denote activities by parentheses.

Of particular interest in freshly erupted volcanics are the systematics of very short-lived ^{238}U daughter nuclides such as ^{222}Rn, ^{210}Pb, ^{210}Po and ^{210}Bi. These elements are all volatile to varying degrees during magmatic processes, and their half-lives (3.8 days, 22 yr, 138 days and 5 days, respectively) are especially suitable for investigating magma degassing. Because each degassed volatile nuclide will follow a predictable ingrowth

pattern relative to a non-volatile parent, its initial concentration in the magma can be determined by monitoring the temporal changes in its activity in a freshly erupted rock. Thus a major difficulty in calculating the degassing efficiency of a given species, estimation of its initial concentration in the magma, is overcome by direct measurement.

The vapour supersaturation and subsequent degassing of Rn, Po and Bi nuclides from freshly erupted subaerial volcanics are well known from studies of both the rocks themselves[9-11] and filtrates of volcanic plume materials[12-17]. In most cases both ^{222}Rn and ^{210}Po are completely degassed from freshly erupted basaltic lavas, and ^{210}Bi is ~20% degassed. Little or no ^{210}Pb degasses. In addition, volcanic ash and plume condensates have large (^{210}Po/^{210}Pb) ratios, up to 120 (ref. 17), and large enrichments of ^{222}Rn are observed in the plume relative to normal air[12].

The Macdonald sample is the first freshly erupted submarine volcanic material to become available for U-series measurements. As in the case for subaerial volcanics, ^{210}Po was 100% degassed from the Macdonald magma on eruption (Fig. 1). In addition, ^{210}Po measurements on sea water collected over the erupting volcano show qualitatively that much of the polonium condensed there. The seawater sample contained ~5 Vol% suspended plume material when collected; by the time of analysis this material had dissolved in the acidified seawater (H. Craig, personal communication). The ^{210}Po concentration, extrapolated to the time of eruption, is 66 d.p.m. dm^{-3}, which is significantly larger than open-ocean surface seawater values of 0.04–0.09 d.p.m. dm^{-3} (refs 18, 19). Furthermore, we recently analysed similar material collected by the *Cyana* expedition in 1989 during eruption of Macdonald. The dried sample contains 970±65 d.p.m. g^{-1} ^{210}Po, extrapolated to the time of eruption, or ~500 times by weight the amount in the analysed rock.

In the Macdonald sample (^{210}Pb/^{226}Ra) = 0.85. The two simplest explanations for this observation are the loss of ^{210}Pb by degassing or the addition of ^{226}Ra (possibly from recently altered crust) to the magma. The required 15% degassing loss is, however, much larger than would be expected from estimates of the Pb degassing efficiency, which are ~1% (ref. 11). This hypothesis is also inconsistent with (^{210}Po/^{210}Pb) ≈ 100 in the *Cyana* slick material (G. McMurtry, personal communication). The addition of Ra is also unlikely because it would imply an unusually low (≤1) indigenous (^{226}Ra/^{230}Th) for the magma before Ra addition. The only intermediate nuclide between ^{226}Ra and ^{210}Pb is gaseous ^{222}Rn, thus it is also possible that Rn loss caused the deficit. The mechanism could include either sustained partial ^{222}Rn degassing from the whole convecting magma chamber over about the past hundred years or complete degassing from a smaller reservoir which was mixed with a fresh undegassed magma just before eruption. Such degassing would affect Rn and other gasses such as Ar, but probably would not affect volatile metals, which are lost only upon eruption.

The volatile metals lost from an explosively erupting magma such as that at Macdonald would include Bi, Cd, Ir, Se, Hg and As[20,21] as well as less volatile elements such as Pb, Cu and Zn, some of which have concentrations as low at 10^{-12} M in sea water. Although it is difficult to extrapolate from a single volcano to an ocean-wide flux, it is nevertheless worthwhile to make the first estimates of the amount of volatile-metal addition to sea water during explosive submarine volcanism at Macdonald. Such input is completely different from the hydrothermally mediated fluxes of various elements during less explosive ridge-crest and (deep) seamount eruptions. The estimated flux of ^{210}Po in d.p.m. yr^{-1} to the ocean from alkalic volcanism at Macdonald is: $(F_{Po}) = V(\overline{^{210}Po})\rho E_{Po}/\Delta t$, where V is the volume of magma produced, ($\overline{^{210}Po}$) is the average activity of ^{210}Po, ρ is the approximate magma density, E_{Po} is the Po degassing efficiency and Δt is the time interval. Based on observations of ocean islands today, reasonable estimates for the volume and duration of post-shield alkalic volcanism are ~5% of the volcano volume and 300,000 yr. From this we infer a present-day effusion rate at Macdonald of 1.67×10^{-5}% of the volcano volume per yr. Using 4.34×10^{12} m^3 for the total volume of Macdonald, ($\overline{^{210}Po}$) = 1.43 d.p.m. g^{-1}, ρ = 2.9 g cm^{-3} and a degassing efficiency of 100% (E_{Po} = 1), it is estimated that the average present-day flux of ^{210}Po from Macdonald is 3.0×10^{12} d p.m. yr^{-1}.

With some further assumptions, it is possible to estimate the present-day flux of other metals from Macdonald to sea water. For subaerial volcanoes, Lambert and coworkers[22] used E_{Pb} = 0.01 to calculate the volcanic F_{Pb} using plume ^{210}Po measurements and E_{Po} = 1. All other element fluxes were then normalized to the Pb flux using the equation $F_X = F_{Pb}(E_X C_X)/(E_{Pb} C_{Pb})$, where C_X is the average concentration of the element of interest in the erupted rocks. Using published values of E for Pb, Cd, Zn, Cu and Bi[23], an average of 0.3 d.p.m. ^{210}Pb per μg Pb in Austral–Cook alkali basalts (inferred from data in ref. 24) and average concentrations for these elements in similar rocks, we use the same approach and obtain approximate fluxes from Macdonald (in 10^{-4} Gg yr^{-1}) of 1, 0.4, 2, 6 and 0.6 for these elements, respectively. These are consistently 0.004% of the calculated global subaerial volcanic aerosol output[22] and range from 0.002% (Cu) to 3×10^{-7} (Pb) of the calculated anthropogenic atmospheric input (significant only within the last century) of these metals[25]. Although these fluxes seem relatively small by comparison, neither the oceanic inputs nor the river fluxes from these latter sources are well known, and all fluxes have considerable associated error. Obviously, the total volatile input to sea water depends upon the unknown number of active Macdonald-like volcanoes but it seems to be a minor component of the total budget for these elements.

Regardless of the global budgets, explosive submarine volcanism must have a large impact on the local budget for these elements, especially if the volcanoes are located in areas isolated from continental inputs. For elements having short oceanic residence times, one would expect pulses of scavenged-volatile-element enrichment in sediments near seamount volcanoes

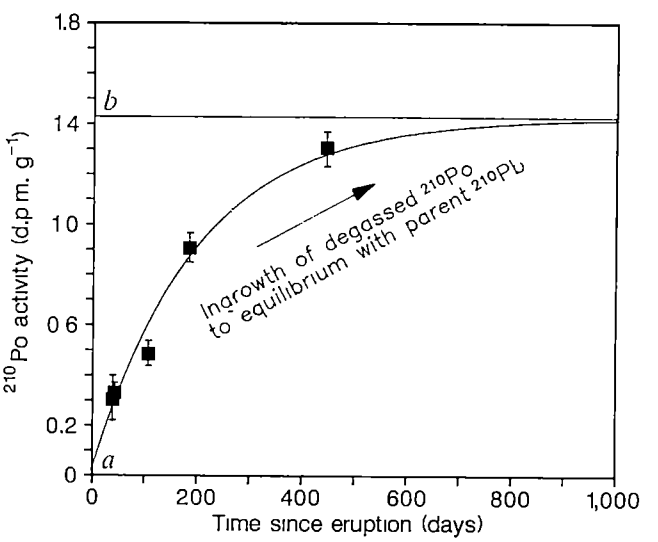

FIG 1 The ingrowth of (^{210}Po) (d.p.m g^{-1}) in the analysed rock as a function of time since the eruption The exponential curve is a best fit to the data and shows that the initial ^{210}Po activity upon eruption *a* was 0 02± 0 08 d p m. g^{-1} and the ^{210}Pb activity to which it is growing *b* is 1 4± 0.1 d.p m g^{-1}. The effect of the possible partial degassing of ^{210}Bi (the only intermediate nuclide between ^{210}Pb and ^{210}Po) is only apparent in the first 25 or so days after eruption Therefore, the effective ingrowth of degassed ^{210}Po to equilibrium with grandparental ^{210}Pb is governed by the equation $(^{210}Po)_t = (^{210}Po)_i e^{-\lambda t} + (^{210}Pb)(1 - e^{-\lambda t})$ where λ is the ^{210}Po decay constant and t, in this case, is the time since eruption (^{210}Po) was measured by autoplating the metal on to Ag planchets from solutions of the dissolved rock[37]. The error bars show 2σ counting uncertainty

TABLE 1 Isotope data for Macdonald seamount

Th (p p m)	4 3 ± 0.3	Th/U	2 6 ± 0.5
U (p p m)	1.7 ± 0.1	$[Th/U]_s$	2 1 ± 0 2

(^{234}U)	1.30 ± 0 07	($^{234}U/^{238}U$)	1.04 ± 0.06
(^{232}Th)	1.04 ± 0.05	($^{230}Th/^{238}U$)	1.2 ± 0.1
(^{230}Th)	1 5 ± 0.1	($^{226}Ra/^{230}Th$)	1.12 ± 0 09
(^{226}Ra)	1.70 ± 0.07	($^{210}Po/^{226}Ra$)	0 84 ± 0 08
(^{210}Pb)	1.4 ± 0.1	($^{210}Po/^{210}Pb$)$_t$	0.01 ± 0.04
(^{210}Po)$_{sw}$	66 ± 20	$^{144}Nd/^{143}Nd$	0.51283 ± 0 00001·
(^{210}Po)$_{slk}$	970 ± 65	$^{87}Sr/^{86}Sr$	0.70366 ± 0 00003

Activities (in d.p.m. g^{-1}) and activity ratios of U-series nuclides in fresh Macdonald seamount basalt U and Th isotopes were measured by high-resolution alpha spectrometry (see, for example, ref 31) (^{226}Ra) was measured by the ^{222}Rn-emanation method (see, for example, ref 36) (^{210}Po)$_{sw}$ is the average initial activity (d.p.m dm^{-3}) in seawater collected during the 11 October 1987 eruption based on measurements made on 2 February and 23 February 1988. (^{210}Po)$_{slk}$ is the initial activity in slick material collected during the 1 February 1989 eruption based on a single measurement made on 13 June 1989 Sr and Nd isotopic ratios were measured by thermal-ionization mass spectrometry. Th/U is the value observed in the rock and $[Th/U]_s$ is the source value calculated from ($^{230}Th/^{232}Th$).

independent of any volcanic ash component. The occurrence of such horizons could help provide dates for alkalic magmatic activity at now dormant volcanoes, for example along a hot-spot seamount chain.

In addition to the isotopes already discussed, we measured other U-series nuclides (Table 1) which help to characterize the volcanism at Macdonald. We note that the activity ratios ($^{226}Ra/^{230}Th$) and ($^{230}Th/^{238}U$) are within the range of values for other ocean island basalts (OIB) (refs 26, 27 and our unpublished data); the ^{226}Ra excess constrains the crustal residence time of the magma to ≤8,000 yr, and ($^{230}Th/^{232}Th$) is high and considered in isolation, implies a low value (~2.1) of Th/U in the source. This is more similar to values characteristic of the mid-ocean-ridge basalt (MORB) source than of the OIB source (refs 26, 28–31). On the Th–Sr isotope diagram, the Macdonald seamount datum falls far above the broad array defined by oceanic rocks[32], suggesting that either the Sr or Th isotopic ratios have been affected by secondary processes. Comparison of our Macdonald seamount Sr and Nd data (Table 1) with those from other nearby eastern Austral–Cook islands[24,33] suggests that $^{87}Sr/^{86}Sr$ is indeed high for the measured Nd isotopic composition and that the source Sr isotopic ratio may be closer to 0.7028. If this is so, the Sr–Th isotope correlation indicates that ($^{230}Th/^{232}Th$) should be close to 1.25, considerably lower than the measured value but still far above the OIB range, indicating a truly depleted source for Macdonald.

The process most likely to cause the secondary isotope shifts is the incorporation of altered oceanic crustal materials, because both U concentration (and hence ^{230}Th) and $^{87}Sr/^{86}Sr$ increase during alteration. To change $^{87}Sr/^{86}Sr$ from 0.7028 to 0.7073 and ($^{230}Th/^{232}Th$) from 1.25 to 1.5 would require about 14% of the Sr and 17% of the ^{230}Th to come from the alteration component. Similar processes have been postulated to occur at other localities (for example, Kiluea[34] and Iceland[35]). Furthermore, the frequent explosive magmatism, the observed release of large quantities of gas during recent eruptions, and the presence of scoriaceous spatter cones at the summit suggest that Macdonald is presently erupting highly gas-charged lavas. This implies a large increase of gas pressure over a short time interval to permit rapid gas build-up and is consistent with the effective sealing of chamber-to-surface magma conduits by seawater circulation through the crust between eruptions. □

Neuronal correlates of a perceptual decision

William T. Newsome*†, Kenneth H. Britten*† & J. Anthony Movshon‡

THE relationship between neuronal activity and psychophysical judgement has long been of interest to students of sensory processing. Previous analyses of this problem have compared the performance of human or animal observers in detection or discrimination tasks with the signals carried by individual neurons, but have been hampered because neuronal and perceptual data were not obtained at the same time and under the same conditions[1–4]. We have now measured the performance of monkeys and of visual cortical neurons while the animals performed a psychophysical task well matched to the properties of the neurons under study. Here we report that the reliability and sensitivity of most neurons on this task equalled or exceeded that of the monkeys. We therefore suggest that under our conditions, psychophysical judgements could be based on the activity of a relatively small number of neurons.

† Present address Department of Neurobiology, Stanford University Medical School, Stanford, California 94305, USA

Our general methods for monitoring unit activity and eye position in alert, behaving monkeys are derived from those devised by Wurtz *et al.*[5] and our psychophysical methods were based on those described by Newsome and Paré[6]. In brief, animals were trained to report the direction of motion of a random dot display in which some dots moved coherently while the remainder moved at random. We varied the strength of the motion signal by varying the proportion of the dots moving coherently: at 0% correlation, all the motion was random; at 100% correlation, all the motion was coherent. Near threshold, the stimulus resembled the dynamic noise seen on a domestic television set tuned between stations, combined with a barely perceptible sensation of global motion. We recorded single-neuron activity from area MT (V5), a region of the extrastriate visual cortex concerned with motion processing, where most neurons respond optimally to visual stimuli of a particular direction and speed of motion[7–10]. Because efficient extraction of motion signals from this stimulus requires considerable integration over space, it seemed likely that neurons in MT, which have relatively large receptive fields, would be particularly suited to this task. Newsome and Paré[6] have recently shown that lesions of MT elevate perceptual thresholds for this task.

We used a two-alternative forced-choice procedure to measure thresholds. We placed our stimulus so that it just covered the receptive field of the neuron under study, and adjusted the speed to match that preferred by the neuron Motion was presented either in the neuron's preferred direction or in the 'null' direction 180° away. On an individual trial, the monkey was required to hold fixation for 2 seconds while the motion stimulus was presented. At the end of the trial, the monkey indicated his judgment by transferring his gaze to one of two small light-emitting diodes, corresponding to the preferred or null direction of motion. We presented at least 30 trials (15 in each direction) for each of several correlation values chosen to elicit performance that varied from chance to near perfection, and compiled these data into psychometric functions. Recalling that performance would be 50% correct by chance, we defined the threshold as the correlation required for the monkey to judge the direction of motion correctly on 82% of the trials.

While measuring the psychophysical threshold, we recorded the activity of the MT neuron for which the stimulus parameters were optimized. The computer counted the action potentials elicited on each trial, and compiled distributions like those shown for a typical neuron in Fig. 1*a*. In these distributions, filled bars represent trials in which the motion was in the null direction, and cross-hatched bars indicate trials for the preferred direction. It is evident that at a correlation of 0 8% the two distributions were not different, whereas at a correlation of 12.8%, where the neuron was strongly direction-selective, they barely overlapped. To compare these neuronal data with the psychophysical data, we postulated that performance depended on a comparison between the activity of two neurons, the one under study and another differing only in that it preferred the opposite direction of motion Under this assumption, we could use the distributions in Fig. 1*a* to represent the responses of the neuron under study and its 'antineuron'; we simply reversed the preferred and null directions for the antineuron. On any individual trial, therefore, the observer would compare a response drawn from the distribution represented by the hatched bars in Fig. 1*a* with one drawn from the distribution represented by the solid bars. The direction chosen would be the preferred direction of the neuron giving the larger response. The performance of an MT neuron could then be characterized as the probability that a randomly selected response from the hatched distribution in Fig. 1*a* was larger than a randomly selected response from the solid distribution. We chose this method for analysing physiological data because it most directly related neuronal performance to the directional discrimination task that the monkey was engaged in.

For the data in Fig. 1*a*, at a correlation of 0.8%, this decision

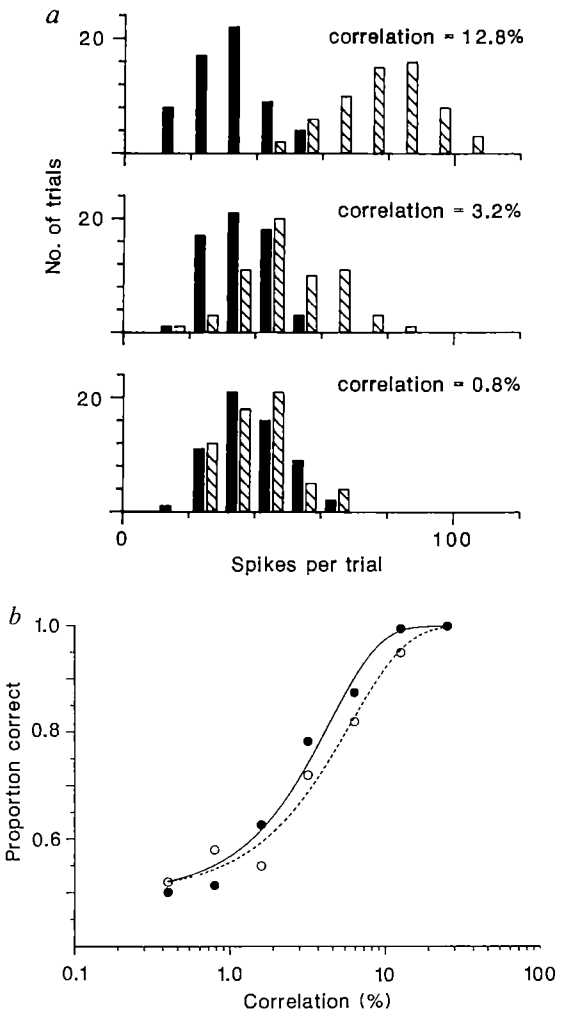

FIG 1 Physiological and psychophysical data obtained simultaneously from a rhesus monkey *a*, The responses of a directionally selective MT neuron at three different motion correlations spanning physiological threshold The hatched bars represent responses to motion in the neuron's preferred direction, the solid bars indicate responses to motion in the null direction (180° opposite to the preferred) Sixty trials were performed in each direction for each of the three correlation levels Response distributions for a range of correlation levels were used to compute a 'neurometric' function that characterized the neuron's sensitivity to the motion signal and could be compared with the psychometric function computed from the monkey's behavioural responses *b*, Comparison of simultaneously recorded psychometric and neurometric functions Psychophysical performance of the monkey, ○; performance of the neuron, ●. Psychophysical performance at each correlation is given by the proportion of trials on which the monkey correctly identified the direction of motion Neuronal performance is calculated from distributions of responses like those in Fig 1*a*, using a signal-detection method described in the text. The physiological and psychophysical data form similar curves, but the data for the neuron lie to the left of the data for the monkey, meaning that the neuron was somewhat more sensitive than the monkey We fit the data with smooth functions of the form introduced to psychophysics by Quick[12] Threshold, defined as the correlation for which the direction of motion was identified correctly on 82% of the trials, was 6 1% for the monkey and 4 4% for the neuron

rule chose the correct direction only on about half the trials (random performance), whereas at a correlation of 12.8% it performed nearly perfectly. We used a method based on signal detection theory[11] to estimate this choice probability for each correlation value, and plotted the results as 'neurometric functions' formally equivalent to the psychometric functions representing the psychophysical data[2,4]. The two functions for this example neuron are shown in Fig. 1*b*; filled circles represent neurometric data, open circles represent psychometric data. Evidently the two curves are very similar, with the neurometric

data points lying slightly to the left of the psychometric data points; in this case the neuronal threshold was slightly lower than the psychophysical one. We used a likelihood-ratio statistic to test the hypothesis that the psychometric and neurometric functions were the same. For this neuron, this hypothesis could not be rejected ($P > 0.05$).

We performed this analysis for 45 neurons recorded from one monkey, and 15 neurons from a second. Figure 2 shows a histogram of the distribution of the ratio of neurometric to psychometric thresholds for these 60 neurons. Values of this ratio of <1 represent cases where the neuron's threshold was lower than the monkey's; values >1 represent cases where the monkey's performance was better than the neuron's. Intuitively, it might be expected that the behavioural threshold would be lower than any particular neuronal threshold but, in most cases, neuronal thresholds and perceptual thresholds were similar. Indeed in some cases, neuronal thresholds were substantially *lower* than perceptual thresholds. For 20 of the 60 neurons in our sample, the psychometric and neurometric functions were statistically indistinguishable ($P > 0.05$); in 18 of the 40 remaining cases, neuronal thresholds were lower than perceptual thresholds. In other words, if the monkeys were able to select and measure the discharge of some of these neurons as we did, their performance could have been better than it actually was.

An inability to select the most informative signals can be considered as a kind of perceptual uncertainty, of the kind modelled by Pelli[13]. Obliged to monitor signals from many sources less informative than the one perfectly tuned to the visual target, the animal's perceptual performance would be degraded, because each sub-optimal source would contribute more noise than signal. Neuronal performance would then exceed psychophysical performance. Our results suggest, however, that this effect is not large. Substantial uncertainty would make the psychometric function steeper than the neurometric function[13], but as was the case for the example shown in Fig. 1*b*, the slopes of these two functions are usually similar. We thus conclude that under our conditions, the monkey's perceptual decision is not greatly affected by irrelevant signals introduced by uncertainty.

The apparent absence of uncertainty leads, however, to another question: if a perceptual decision can be based with relative certainty on the discharge of the most informative neurons, why is behavioural performance not further enhanced by using a pooled signal derived from many such informative neurons? If enough such neurons were present, such pooling would substantially improve psychophysical performance by averaging out the noise that obscures weak signals. Our data show that in most cases, the neuronal and psychophysical performances are similar, indicating that signals from many neuronal sources are not pooled to reduce perceptual thresholds.

One way to account for the absence of either pooling or uncertainty effects is to suggest that the variability in the responses of similarly tuned neurons is correlated. Both pooling and uncertainty act as we have stated only if different neuronal signals are perturbed by *independent* sources of variation. If the sources are not independent, then uncertainty does no damage and pooling provides no benefit, because different neurons are carrying similar signals. The rich network of shared connections that link MT neurons with the retina might well produce correlation among neurons with related selectivities, but this possibility has not been studied. Our lack of information about the degree of shared variability makes it impossible for us to assert that the neurons whose responses we have recorded are the ones that contribute to the monkey's perceptual judgements. Nonetheless, our results show that a reasonable account of the monkey's performance can be constructed, using a simple decision rule, from signals carried by small numbers of neurons whose selectivities are well matched to the demands of the perceptual task. □

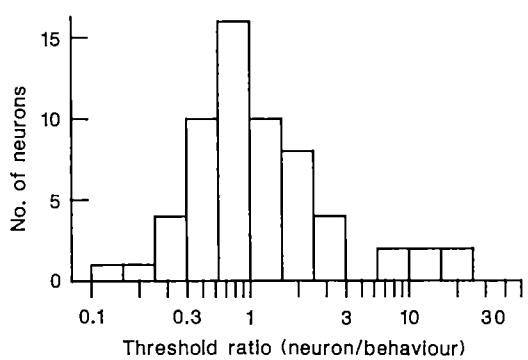

FIG. 2 Comparison of psychophysical and physiological thresholds obtained for 60 MT neurons in two rhesus monkeys. The frequency histogram shows the distribution of the ratio of the physiological threshold to the psychophysical threshold for all the neurons for which we obtained data. A value of 1 represents perfect correspondence between psychophysical and physiological thresholds; values <1 indicate that the physiological threshold was lower than the psychophysical threshold, whereas values >1 indicate the converse. The directional preferences of the 60 neurons were roughly uniformly distributed, and there was no reliable association between a neuron's direction or speed preference and its threshold relative to the perceptual threshold.

THE identification of brain structures and connections involved in memory functions has depended largely on clinico-pathological studies of memory-impaired patients[1–4], and more recently on studies of a primate model of human amnesia[5,6]. But quantitative neurobehavioural data and detailed neuropathological information are rarely available for the same patients[7–9]. One case has demonstrated that selective bilateral damage to the hippocampus causes a circumscribed memory impairment in the absence of other intellectual deficits[9]. This finding, in conjunction with evidence from humans[10,11] and monkeys[12–16], indicates that the hippocampus together with adjacent and anatomically related structures is essential for the formation of long-term memory, perhaps by virtue of

WAIS-R, Wechsler Adult Intelligence Scale-Revised; WMR-R, Wechsler Memory Scale-Revised. The WAIS-R and each of the five indices of the WMS-R yield a mean score of 100 in the normal population with a standard deviation of 15. The WMS-R does not provide numerical scores for subjects who score below 50. Therefore, the single value below 50 was scored as 50 for computing a group mean.

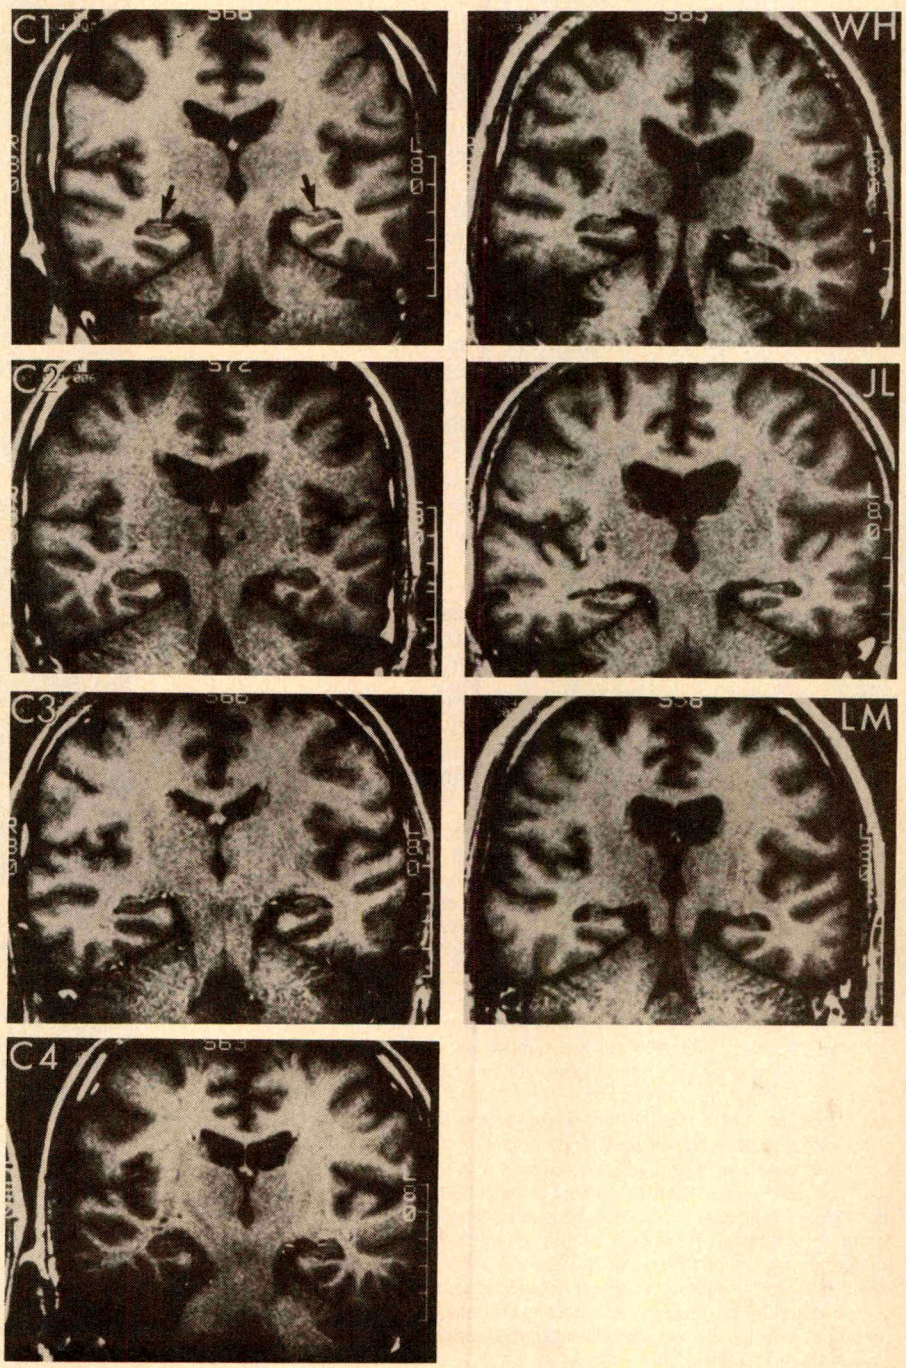

FIG. 1 T1-weighted (TE = 400 ms, TR = 20 ms) images of 5-mm thick slices through the hippocampal formation. These photographs show the first or second of the three levels through the hippocampal formation that were submitted to quantitative analysis. Panels on the left (C1–C4) show images from neurologically intact control subjects, and panels on the right show images from three amnesic patients (W.H., J.L. and L.M.). The area of the hippocampal formation (indicated by arrows in panel C1) in the amnesic patients averaged 49% of the corresponding area in control subjects. In contrast, the average area of the temporal lobe (measured from the fundus of the collateral sulcus to the inferior limiting sulcus) was nearly identical in the two groups. The parahippocampal gyrus is smaller in J.L. than in the other amnesic and control subjects. The photographs show the left side of the brain on the right side of each panel. The calibration bar at the right of each panel represents 5 cm in 1-cm increments.

the extensive reciprocal connections between the hippocampal formation and putative memory storage sites in the neocortex[17]. Although cognitive studies of amnesia provide useful information about the functional organization of normal memory[1,18–21], it has not usually been possible to relate memory impairment to anatomy in living patients. We have developed a high-resolution protocol for imaging the human hippocampus with magnetic resonance that permits visualization of the hippocampal formation in substantial cytoarchitectonic detail, revealing abnormalities in patients with severe and selective memory impairment.

Three male amnesic patients and four male control subjects were examined (Table 1). Patient W.H. became amnesic rapidly over the course of several days in 1986 without antecedent head trauma, seizure or unconsciousness. Patient J.L. became amnesic gradually during a period of about two years (from early 1985 to early 1987); his cognitive status has remained stable since that time. The aetiology in these two cases was unknown. Patient L.M. became amnesic in 1984 as the result of a respiratory arrest which occurred during an epileptic seizure. All three patients were severely impaired on standard tests of verbal and non-verbal memory[22,23]. For example, learning of 10 noun pairs across three trials[24] was 0.3, 0.3 and 1.0 pair (controls; 6.3, 7.5 and 8.5). The amnesic patients performed well on other cognitive tests, such as on the non-memory portions of the Dementia Rating Scale[25] (maximum score, 119; patients, 116.3; controls, 118.3) and on the Controlled Word Association Test (FAS)[26] (patients, 52.0 words; controls, 41.8 words).

Magnetic resonance examinations were performed with a 1.5-tesla superconducting magnet (General Electric, Milwaukee). In preliminary studies, we determined that the optimal resolution of the hippocampus was obtained when the hippocampus was imaged perpendicular to its long axis. Accordingly, each subject was supine on the magnetic resonance examination table within the magnet, and the head was tilted posteriorly so that the line joining the lips and the external auditory canal was perpendicular to the table (and the longitudinal axis of the magnetic field). A sagittal, T1-weighted (TR = 200 ms, TE = 20 ms, 1 excitation (NEX)) spin-echo sequence (field of view (FOV) = 24 cm, matrix = 256 × 128) centred at the mid-line showed the long axis of the hippocampus clearly. The head of the patient was then repositioned slightly if necessary to orientate the hippocampus appropriately. Coronal images were then obtained using a T1-weighted sequence (TR = 400 ms, TE = 20 ms, 6 NEX; FOV = 16, matrix = 256 × 256), which provided six interleaved, 5 mm-thick sections (no interslice gaps) with 0.625 mm in-plane spatial resolution. We obtained the first section just caudal to the pes hippocampus and were able to survey 30 mm of the hippocampus out of a total rostrocaudal length of 40 mm. Coronal proton-density and T2-weighted images (TR = 2,700 ms, TE = 30 and 80 ms, 1 or 2 NEX; FOV 16, matrix = 256 × 256) were also obtained.

The images obtained by our high-resolution, T1-weighted protocol showed the hippocampal formation in considerable detail (Figs 1 and 2). For example, Fig. 2*a* illustrates in a normal subject the pyramidal cell fields of the subiculum and hippocampus, the fimbria, perforant path, stratum lacunosum-moleculare, the alveus, and the molecular layer of the dentate gyrus. To calculate areal boundaries within the temporal lobes, we selected slices that were located at about the same rostrocaudal level in each subject. For each series of images, the first section caudal to the pes hippocampus and the two adjacent caudal sections were selected for analysis.

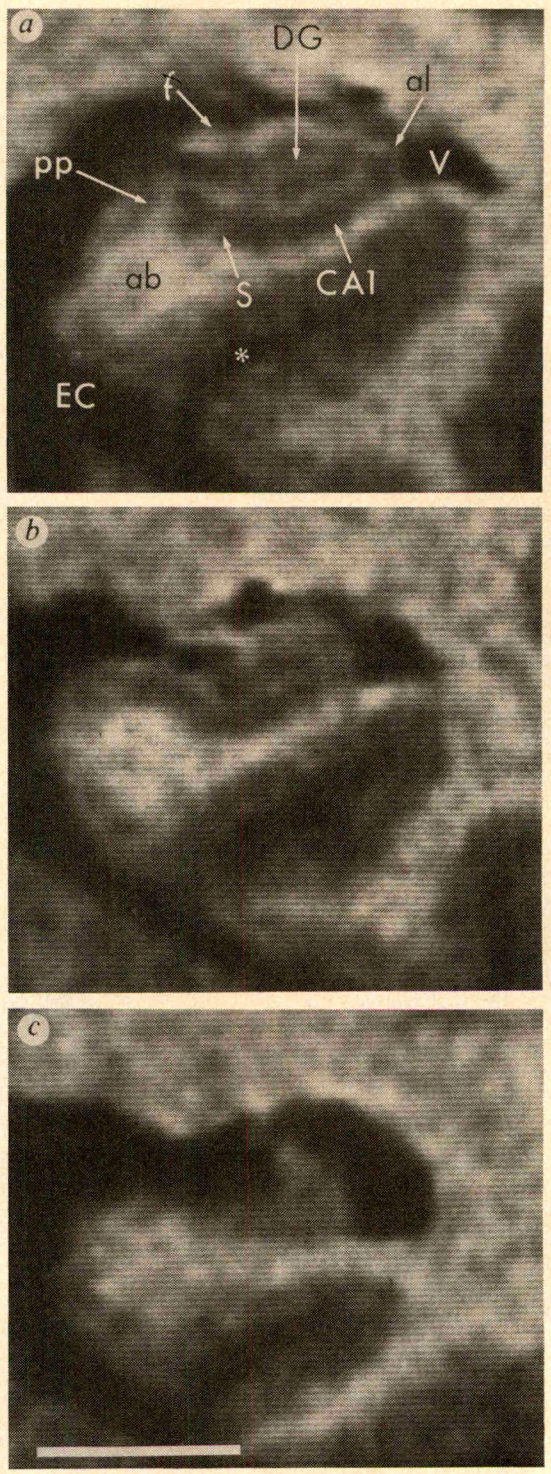

FIG. 2 Higher magnification magnetic resonance images than those shown ► in Fig. 1 of the left hippocampal formation. *a*, T1-weighted image (TE = 400 ms, TR = 20 ms) of a 5-mm thick section through the hippocampal formation of a 24-year-old normal subject. It is possible to distinguish the angular bundle (ab), the perforant path (pp), the alveus (al), the molecular layer of the dentate gyrus (DG), and the fimbria (f). The pyramidal cell layer of the subiculum (S) and the CA1 field of the hippocampus (which are ~1.5-mm thick in the coronal plane at this level) can also be seen. The entorhinal cortex (EC) lies just ventral to the angular bundle. The region of high signal intensity superficial to the pyramidal cell layer marks the stratum lacunosum-moleculare, in which the perforant path projects to the hippocampus and dentate gyrus. The temporal horn of the lateral ventricle (V) lies just lateral and dorsal to the hippocampus, and the asterisk marks the position of the collateral sulcus. *b*, Hippocampal formation of control subject C1 at the same level seen in Fig. 2. Whereas this image is not as distinct as the one from the younger subject, most of the anatomical features identified in that image can also be distinguished here. *c*, Hippocampal formation of amnesic patient L.M. at the same level as in Fig. 1. In contrast to the images in *a* and *b*, the fimbria is not distinct in this image, and it is difficult to determine the boundary of the pyramidal cell layer in the subiculum or hippocampus. In addition, there is marked reduction of the size of the dentate gyrus, hippocampus, and subiculum. The calibration bar represents 1 cm in all three panels.

Using 11 × 14 inch photographs and a microcomputer-linked digitizing tablet, the area of the hippocampal formation (defined as the fimbria, dentate gyrus, hippocampus proper and subiculum) was computed on each side and in each of the three sections. We then measured the combined area of the hippocampal formation and the parahippocampal gyrus (extending from the subiculum to the fundus of the collateral sulcus) and the area of each temporal lobe (minus the hippocampal formation and parahippocampal gyrus). The outline for the temporal lobe measurement extended from the fundus of the collateral sulcus to the inferior limiting sulcus of the insular cortex. The left and right lateral ventricles and the third ventricle were also measured. We expressed the area of each of the regions as the average per section of the areal values for the sampled sections.

The area of the temporal lobe was nearly identical in the two groups (controls: left temporal lobe, 11.57 cm^2, right temporal lobe, 12.75 cm^2; patients: left temporal lobe, 11.85 cm^2, right temporal lobe, 13.57 cm^2). By contrast, the hippocampal formation (HF) in the patients was markedly reduced in size (controls: left HF, 0.60 cm^2, right HF, 0.67 cm^2; patients: left HF, 0.29 cm^2, right HF, 0.33 cm^2). The area of the hippocampal formation in the patients was 49% of that in the control subjects ($t_5 = 5.4$, $P < 0.01$). The results were the same when the area of the hippocampal formation was calculated as a percentage of the size of the temporal lobe (controls, 5.3%, patients, 2.5%). The lateral ventricles (patients, 4.31 cm^2; controls, 2.84 cm^2) and the third ventricle (patients; 1.05 cm^2; controls, 0.76 cm^2) were somewhat larger in the patients than in the controls, but these differences were not significant ($0.1 > P < 0.05$). Patient J.L. had left and right ventricles outside the normal range; patients J.L. and L.M. had third ventricles outside the normal range. Finally, the area of the parahippocampal gyrus was smaller in patient J.L. (the average area of each side was 1.01 cm^2, or 7.5% of the area of the temporal lobe). The parahippocampal area was nearly the same in the other two amnesic patients as in the control subjects (patients: 1.29 cm^2, 10.5% of the temporal lobe area; controls: 1.28 cm^2, 10.5% of the temporal lobe area).

T2-weighted images revealed no regions of abnormal signal intensity in the brain of patient L.M. The other two patients had non-specific, abnormal, hyper-intense foci in the striatum, as previously reported; for example, in ischaemia, de-myelination, or infarction[27]. Patient J.L. had several additional hyperintense foci distributed in the white matter.

This high-resolution magnetic resonance protocol focused on one area of interest and did not survey all brain regions. Accordingly, we cannot exclude the possibility that additional abnormalities might have been detected if other areas had been surveyed as carefully as the hippocampal formation. Nevertheless, circumscribed memory impairment has been associated previously with histologically confirmed hippocampal lesions in the absence of other significant damage[9], so the abnormalities that we have identified are likely to have contributed substantially to memory dysfunction in all three patients.

Our magnetic resonance protocol has acquired images with a better resolution of the hippocampal formation than is obtained by more standard protocols[28–30]. We attribute this improved resolution to the fact that we obtained images precisely perpendicular to the long axis of the hippocampus. Because damage to the hippocampal formation occurs prominently in Alzheimer's disease[31], and memory impairment is one of its earliest symptoms, this protocol might be useful in achieving an early diagnosis of the disease. □

Intercellular adhesion molecule-1 is an endothelial cell adhesion receptor for *Plasmodium falciparum*

A. R. Berendt, D. L. Simmons*, J. Tansey, C. I. Newbold & K. Marsh

Molecular Parasitology Group and * Imperial Cancer Research Fund, Institute of Molecular Medicine, University of Oxford, John Radcliffe Hospital, Headington, Oxford OX3 9DU, UK

THE primary event in the pathogenesis of severe malaria in *Plasmodium falciparum* infection is thought to be adherence of trophozoite- and schizont-infected erythrocytes to capillary endothelium[1], a process called sequestration. Identifying the endothelial molecules used as receptors is an essential step in understanding this disease process. Recent work implicates the membrane glycoprotein CD36 (platelet glycoprotein IV; refs 2–5) and the multi-functional glycoprotein thrombospondin[6] as receptors. Although CD36 has a widespread distribution on microvascular endothelium[7], it may not be expressed on all capillary beds where sequestration occurs, especially in the brain[8]. The role of thrombospondin in cell adhesion, *in vitro* or *in vivo*, is less certain[4,9]. We have noticed that some parasites bind to human umbilical-vein endothelial cells independently of CD36 or thrombospondin. To screen for alternative receptors, we have developed a novel cell-adhesion assay using transfected COS cells, which confirms that CD36 is a cell-adhesion receptor. In addition, we find that an endothelial-binding line of *P. falciparum* binds to COS cells transfected with a complementary DNA encoding intercellular adhesion molecule-1. As this molecule is widely distributed on capillaries and is inducible[10], this finding may be relevant to the pathogenesis of severe malaria.

We have observed that binding of red blood cells infected with Gambian wild isolates of *P. falciparum*, in the C32 amelanotic melanoma cell adherence assay varies markedly, but does not correlate with severity of clinical malaria[11]. More

recently we have found that there is no correlation between the capacity of individual isolates to bind to C32 cells and endothelial cells (unpublished observations). This also applied to laboratory lines. The cloned parasite line FCR3A2 showed strong CD36-dependent binding to C32 cells but did not bind to endothelial cells, whereas the selected line ITO4, derived from the Brazilian IT isolate, bound to both cell types (Fig. 1). Adhesion of ITO4 infected cells to endothelial cells is not blocked by a range of monoclonal antibodies to CD36 or by a polyclonal anti-thrombospondin antibody (data not shown).

It seemed possible that an additional endothelial receptor could explain these discrepancies and we therefore devised a novel adhesion assay using transiently transfected COS cells[12] as a means of screening for such a receptor.

A cDNA clone coding for CD36 was isolated from a placental cDNA library by transient expression and panning[12]. We first confirmed that transiently expressed CD36 behaved as a receptor for FCR3A2- and ITO4-infected cells. Both lines bound to CD36-transfectants (Fig. 2*c*, *d*) but not to resting or mock-transfected COS cells (Fig. 2*a*, *b*), nor to COS cells transfected with cDNAs encoding CD2 or CD16 (data not shown). Expression of the cDNA by the transfectants was confirmed using appropriate monoclonal antibodies in indirect immunofluorescence assays (data not shown). C32-non-binding parasites, such as T9/96, did not bind to CD36-transfectants.

While screening for other cell-adhesion receptors, we found that as well as binding to CD36-transfectants, erythrocytes infected with ITO4 also bound to COS cells transfected with a cDNA encoding the protein intercellular adhesion molecule-1 (ICAM-1; ref. 13; see Fig. 2*f*). FCR3A2-infected cells did not bind at all to ICAM-1 transfectants (Fig. 2*e*).

The anti-ICAM-1 monoclonal antibody 7F7 (ref. 14) and the anti-CD36 monoclonal antibody IVC7 (ref. 15) were used in binding inhibition experiments. Each antibody reacted only with the appropriate transfectant in immunofluorescence and immunoprecipitation experiments (data not shown). Each antibody blocked adhesion only to the appropriate transfectant (Fig. 3, top). These results exclude either contamination of ICAM-1-

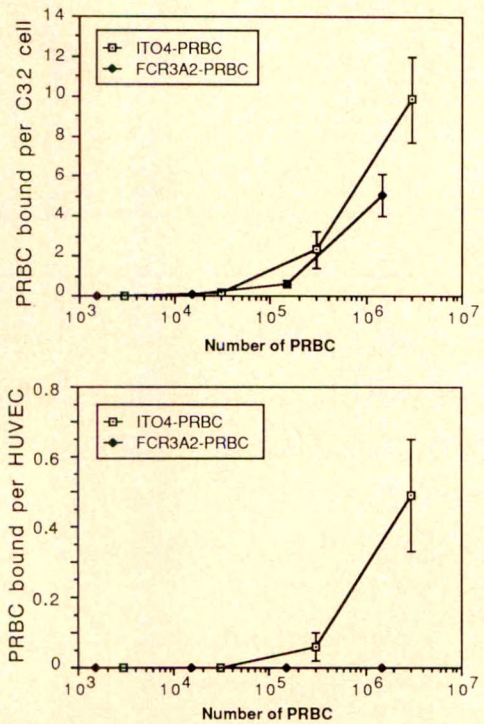

FIG. 1 Comparison of endothelial and melanoma binding of the parasite lines FCR3A2 and ITO4. Binding of parasite-infected red blood cells (PRBC) to C32 melanoma cells (top) or endothelial cells (bottom) is shown for the FCR3A2 clone (closed diamonds) and the ITO4 line (open squares). Points show the means ±1 s.e.m. of triplicate coverslips. Representative data from a single experiment are shown.

METHODS. Parasites were cultured as previously described[24,25] in 96% N_2, 1% O_2, 3% CO_2 and used in binding experiments at mature trophozoite stage at 2% haematocrit, 6% parasitaemia (ITO4) or 3% parasitaemia (FCR3A2). C32 amelanotic melanoma cells were cultured in RPMI 1640 medium, supplemented with penicillin, streptomycin, glutamine and 10% FCS (Gibco) (R10 medium). Human umbilical vein endothelial cells (HUVEC) were isolated and cultured as previously described[26] with minor modifications. Contaminating cord blood cells were removed by centrifugation on 90% Lymphoprep (Nycomed) in serum-free medium at 1,500*g* for 15 min. Endothelial cells and adherent lymphocytes are the only cells retained at the interface (A.R.B., unpublished data). C32 cells were detached with trypsin-EDTA and seeded onto Thermanox 13 mm coverslips at a density of 5×10^3 per coverslip; HUVEC were seeded direct as primary cultures at 10^4 per coverslip. After 48 h they were washed in serum-free medium, fixed for 45 min in 1% formaldehyde in PBS, washed three times in binding medium, and used in the binding assay. Bindings were carried out as previously described for 1 h, gently agitating the coverslips every 10 min. Coverslips were then washed for 1 h by inversion in fresh binding medium, fixed in 1% glutaraldehyde in binding medium, stained in 5% Giemsa for 20 min, dried, mounted in DPX mountant and counted. Counting was performed blind; 200 melanomas or 300 endothelial cells were counted and the binding expressed as number PRBC bound per target cell.

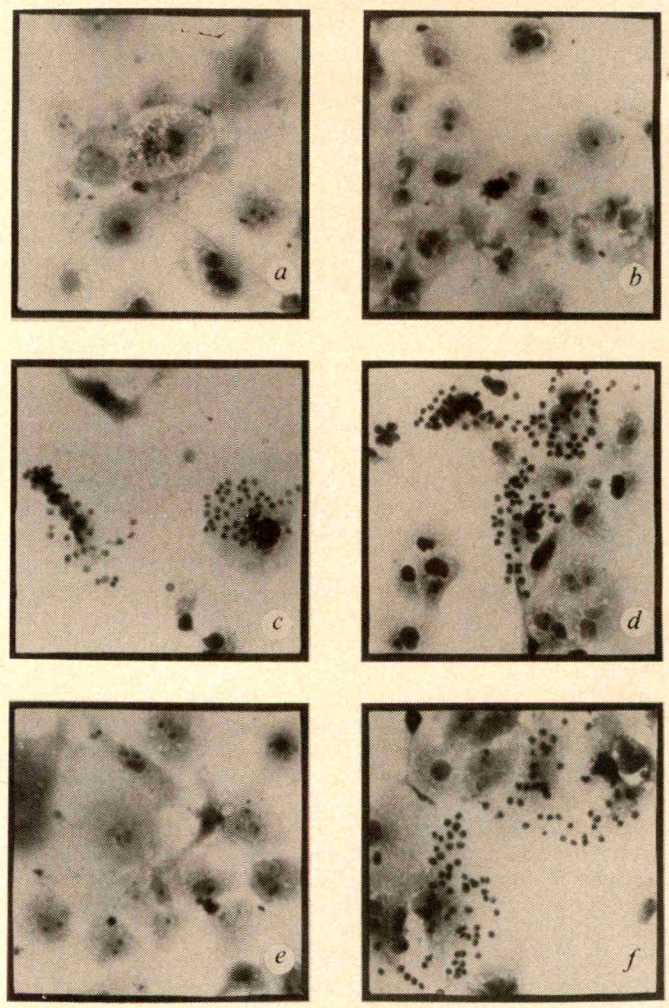

FIG. 2 Binding of PRBC to transiently transfected COS cells. Target cells are mock-transfected COS cells (*a*, *b*), CD36-transfectants (*c*, *d*) or ICAM-1-transfectants (*e*, *f*). Erythrocytes infected with FCR3A2 (*a*, *c*, *e*) or ITO4 (*b*, *d*, *f*) were used in the binding assay.

METHODS. COS cells were transfected with cDNA molecules cloned in the CDM7 expression vector as previously described[12]. After transfection (24 h) the cells were detached with trypsin-EDTA, seeded onto 13 mm Thermanox coverslips at a density of 10^4 cells per coverslip and cultured in R10 medium. After 24–48 h, coverslips were washed in serum-free medium and fixed for 45 min in 1% formaldehyde in PBS. Binding assays were performed as above.

cDNA with CD36-cDNA or a cross-reacting epitope mediating binding. The control monoclonal antibody W6/32, which recognizes a monomorphic HLA determinant on both human and COS cells, had no effect on binding.

When the monoclonal antibodies were tested on cultured endothelium, the binding of ITO4 was significantly inhibited by anti-ICAM-1 antibody, but little affected by anti-CD36 antibody (Fig. 3, bottom). The converse applied to ITO4 binding to C32 melanoma cells. The ITO4 line thus principally uses CD36 as a receptor on C32 cells, but binds to ICAM-1 on cultured endothelium. By contrast, FCR3A2 binds in a CD36-dependent manner to C32 cells and transfected COS cells, but cannot bind to ICAM-1 transfectants or to endothelium. The ability to bind to ICAM-1 is therefore not a universal feature of all binding parasite lines. It has previously been noted that parasite binding to cultured endothelium is consistently lower than binding to C32 cells[16,17]. These data could now be explained by the use of different receptors, and a variable degree of ICAM-1 expression in different endothelial cultures.

ICAM-1, a variably glycosylated glycoprotein, is a ligand for the leucocyte integrin LFA-1 (refs 13, 18). It permits antigen-independent interactions between cells of the immune system and seems to play a central role in the generation of the immune response[14,19,20]. It is also widely distributed on capillary endothelium, where it may be involved in lymphocyte adhesion[10]. Levels of ICAM-1 can be up-regulated both *in vitro* and *in vivo* on endothelial cells in response to tumour necrosis

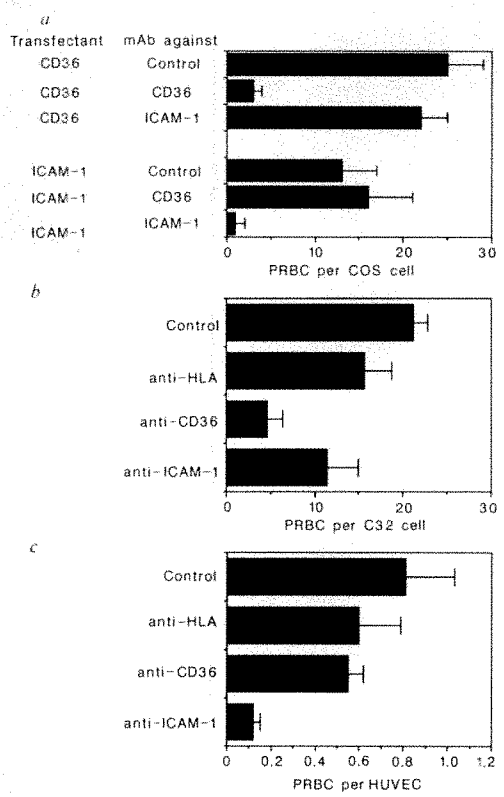

FIG. 3 Effect of monoclonal antibodies on binding of ITO4-infected erythrocytes to transfected COS cells (*a*), C32 cells (*b*) and HUVEC (*c*). Monoclonal antibodies: 7F7 (anti-ICAM-1); IVC7 (anti-CD36); W6/32 (anti-HLA as control antibody). Bars, labelled control, no antibody included. Points are means ±1 s.e.m. of triplicate coverslips. Representative data from a single experiment are shown.

METHODS. Target cells were prepared as for Figs 1 and 2, and used in binding assays as above. Antibody was diluted 1:100 in binding medium (ascites exudate, IVC7 and 7F7) or 1:20 (culture supernatant, W6/32) and incubated with fixed coverslips at room temperature for 60 min. Coverslips were dip-washed in binding medium three times to remove unbound antibody, and used in the binding assay as above. Binding to transfectants was quantitated by counting 300 COS cells from blinded coverslips and deriving the mean number of PRBC bound per binding COS cell.

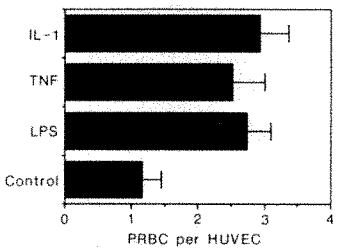

FIG. 4 Binding of ITO4-infected erythrocytes to resting and stimulated endothelium. Points are means ±1 s.e.m. of triplicate coverslips. Representative data from a single experiment are shown.

METHODS. Secondary cultures of endothelium were detached and seeded onto coverslips as above. After 48 h they were washed and the medium replaced with fresh growth medium containing no mediator (control), recombinant human tumour-necrosis factor (TNF) at 200 U ml^{-1}, recombinant human interleukin-1 (IL-1) at 50 U ml^{-1}, or bacterial lipopolysaccharide (LPS) at 1 $\mu g\ ml^{-1}$. After 12 h the coverslips were washed and used immediately in the binding assay as above.

factor (TNF), interleukin-1, and γ-interferon[21,22]. We therefore examined the binding of ITO4-infected cells to cytokine and endotoxin-stimulated endothelium and found increased levels of binding after stimulation (Fig. 4).

In acute malaria, increased levels of cytokines, notably TNF, have been detected and seem to correlate with disease severity (ref. 23 and D. Kwiatowski, personal communication). The identification of ICAM-1 as an additional cell-adhesion receptor raises the possibility that cases of severe malaria occur when parasites that can bind strongly to ICAM-1 coincidentally infect individuals with high endothelial levels of ICAM-1. Sequestration would also occur in those capillary beds where CD36 is expressed, so that the final clinical outcome would reflect the balance between the parasite-determined affinities for different receptors and the host-specific levels of these receptors. Further studies are in progress to address these questions. □

Note added in proof: The sequence of the CD36 cDNA clone described in this paper is identical to that recently reported by Oquendo *et al.*[27]. We have found no significant homologies between CD36, ICAM-1 and thrombospondin.

† To whom correspondence should be addressed

T LYMPHOCYTES are found not only as recirculating cells in the lymphoid system, but also as immobile cells in certain epithelia. T-cell antigen receptors (TCR) of both α/β and γ/δ-heterodimer subtypes can exhibit an extremely high degree of diversity. The diversity of α/β TCRs derives from the use of a large number of variable (V) gene segments, as well as junctional diversity generated during rearrangement of these segments, whereas the diversity of γ/δ TCRs derives largely from junctional elements, with a smaller contribution from a limited number of V gene segments[1]. Many T cells in the epidermal and intestinal epithelia of mice express TCR composed of γ/δ heterodimers[2–5,14,15]. We demonstrate here that γ/δ TCRs of T cells in both these tissues are restricted in V gene usage, with different elements predominating. The TCR junctional diversity of epidermal T cells, however, is extremely limited, whereas that of intestinal T cells is extremely diverse. The distinctive features of these two populations suggest that they develop or are selected differently for particular tissue-specific functions.

Uncultured polyclonal dendritic epidermal cell (dEC) populations in most mouse strains predominantly use $V_{\gamma 3}$ and $V_{\delta 1}$ gene segments[6–9]. We examined rearrangements of these segments in a polyclonal population of dEC-enriched epidermal cells. As shown in Fig. 1, the junctions of 18 out of 21 potentially productive $V_{\gamma 3}$-$J_{\gamma 1}$ rearrangements were identical, as were the junctions of 12 out of 15 $V_{\delta 1}$-$J_{\delta 2}$ rearrangements. These predominant $V_{\gamma 3}$-$J_{\gamma 1}$ and $V_{\delta 1}$-$J_{\delta 2}$ rearrangements were also identical to those previously found in each of five independently derived dEC clones[6]. In contrast, no one sequence predominated in the dEC $V_{\delta 1}$-$J_{\delta 1}$ rearrangements. In the predominant $V_{\gamma 3}$ and $V_{\delta 1}$ sequences, as well as in most of the other dEC TCR rearrangements, non-germline encoded nucleotides (NGE, or N-regions[10–11]) were absent, although a few contained one or two NGE bases. These data thus support the conclusion that the TCR repertoire of dEC is severely limited. In addition, the use of $V_{\gamma 3}$ and $V_{\delta 1}$ gene segments, the minimal amount of NGE insertion, and the use of $D_{\delta 2}$ alone in these rearrangements are also characteristic of the rearrangements found early in fetal development[12,13], supporting the model of an early fetal origin of dEC[6,7].

Another epithelium-associated T cell is the intestinal intraepithelial lymphocyte (IEL)[14–18]. Previous studies[14,15,18] and our results (not shown) suggest that the majority of IEL γ chains are encoded by the $V_{\gamma 5}$ gene. Polymerase chain reaction (PCR) products of predicted sizes were obtained when IEL DNA was amplified with the $J_{\gamma 1}$ primer and either $V_{\gamma 2}$, $V_{\gamma 4}$, or $V_{\gamma 5}$ (refs 13, 20) primers, but no product was obtained with $V_{\gamma 3}$ or $V_{\gamma 1}$ primers (data not shown).

Only one of twelve IEL $V_{\gamma 2}$ subclones represented a productive rearrangement (Fig. 2*a*). One single sequence accounted for 9 out of 11 productive $V_{\gamma 4}$ rearrangements, and a second

FIG. 1 Junctional sequences of $V_{\gamma 3}$ and $V_{\delta 1}$ rearrangements in dEC. *a*, Rearrangements of $V_{\gamma 3}$ to $J_{\gamma 1}$. *b*, Rearrangements of $V_{\delta 1}$ to $J_{\delta 2}$. *c*, Rearrangements of $V_{\delta 1}$ to $J_{\delta 1}$. 'N' denotes nucleotides not present in germline sequences. Because of shared sequences at the ends of some germline gene segments, assignment of nucleotides to one segment or the other in this and other figures is sometimes arbitrary. The sequences are designated as productive (+) or non-productive (−) rearrangements as regards the reading frame of the J segment. The number of sequences presented for any one V gene segment, in this and other figures, does not necessarily indicate the relative levels of V gene segment rearrangement or expression. Asterisks mark sequences previously found in dEC clones[6].
METHODS. Epidermal cells from Balb/c mice were enriched for dEC by Ficoll-hypaque density gradient centrifugation[28] and genomic DNA prepared by phenol extraction and ethanol precipitation. Sequences spanning recombination junctions were amplified by PCR[6,29] and the products digested by appropriate restriction endonucleases and gel-purified before ligation to M13mp18 or M13mp19. PCR primers used were: GCACTGGATCCAACTGAAAGAAG($V_{\gamma 3}$), GGGAAGCTTACCAGAGGGAATTACTATGAG($J_{\gamma 1}$), AATAGGAATTCTACTGATGGTGG($V_{\delta 1}$), GGGGAATTCTTGGTTCCACAGTCACTTGGG($J_{\delta 1}$) and GGGGGAAGCTTGGGGCTCCACAAAGAGC($J_{\delta 2}$). Subclones containing appropriate inserts were picked at random or after screening plaques with ^{32}P-labelled PCR primers, and sequenced by the dideoxy chain-termination method with the Sequenase enzyme (USB).

sequence accounted for 11 of the 18 non-productive rearrangements (Fig. 2*b*), suggesting that only very few IEL have $V_{\gamma 4}$ rearrangements; the PCR amplification might then yield a product biased towards only a few productive or non-productive sequences. In contrast, 24 out of 26 $V_{\gamma 5}$ rearrangements were productive (Fig. 2*c*). The majority of these sequences contained from 1–8 NGE nucleotides and the ends of both the *V* and *J* segments were often shortened substantially, generating considerable diversity in the junctions. A codon for tyrosine is present in many of the $V_{\gamma 5}$–$J_{\gamma 1}$ junctions (Fig. 2*d*), suggesting a possible shared specificity for an antigen or restriction element.

IEL δ-chain genes were amplified using *V*-region primers that correspond to seven published V_δ gene segments[12,21,22], in combination with the $J_{\delta 1}$ and $J_{\delta 2}$ primers. Large amounts of product were obtained with $V_{\delta 4}$ and $V_{\delta 6}$ primers and smaller or miniscule amounts with the others (not shown). This is consistent with the levels of messenger RNA observed on northern blot analysis (not shown), and indicates that the predominant V_δ gene segments used by IEL are a subset of the total V_δ pool[21]. It is apparent that all the various mechanisms for increasing TCR gene junctional diversity are fully used in IEL δ-chain rearrangements (Fig. 3), including use of multiple *D* and different *J* gene segments, insertion of NGE nucleotides, and imprecise joining[1,18]. The extent of such diversity is very similar to that seen in the δ-chain rearrangements of adult thymocytes[21] or splenic γ/δ T cells[23], again in sharp contrast to the limited diversity of dEC[6,9] or early fetal thymocyte δ-chain rearrangements[12].

We have previously suggested that the development of T cells within the thymus may be divided into two broad periods[6,7,24]. In the first phase, the relative 'immaturity' of the recombinase machinery and a restricted pool of accessible gene segments may limit the extent to which TCR repertoires can be broadened[12,13]. During the later phase, use of a larger subset of all germline gene segments, as well as the presence of the 'mature' recombination machinery combine to yield an extremely diverse population of TCRs[18,21,23]. On the basis of the data reported here, we suggest that dEC represent the products of the earlier stage of T-cell development, and IEL are produced during the later, more mature phase.

The difference in the level of TCR diversity may provide insight into the immunological role of these two types of T cells. The normal functioning of the intestinal epithelium involves constant contact with a wide variety of biological compounds and microorganisms, and pathogenic invasion of this tissue may be comparatively frequent. Recent studies have indicated that IEL may be activated *in situ* to acquire cytolytic capability by exposure to normal intestinal biota[17]. The TCR repertoire of IEL may therefore need to be large in order to encompass this spectrum of bacteriological antigens. The normal function of the skin, however, is to serve as a barrier, isolating the epidermis and lower tissues from the environment. Contact of any one dEC with many different antigens may be rare, limiting the utility of a highly diverse TCR repertoire. Dendritic epidermal cells may instead recognize a common cellular product generated in response to pathogenic exposure. We have speculated that a possible target for this 'trauma signal surveillance' by dEC might be endogenous heat-shock proteins, induced in epidermal cells by a variety of cellular insults[6,25]. It has recently been found that many γ/δ T cells react to mycobacterial heat-shock proteins[26,27], a possibility we are currently exploring for dEC. □

FIG. 2 Junctional sequences of γ-chain rearrangements in IEL. *a*, $V_{\gamma 2}$ junctions. *b*, $V_{\gamma 4}$ junctions. *c*, $V_{\gamma 5}$ junctions. *d*, Peptide sequences encoded by IEL $V_{\gamma 5}$ junctions.

METHODS. Genomic DNA in crude cell lysates of IEL[17] from C57Bl/6J mice was amplified by PCR with primers specific for $J_{\gamma 1}$ and either $V_{\gamma 1}$, $V_{\gamma 2}$, $V_{\gamma 3}$, $V_{\gamma 4}$ or $V_{\gamma 5}$. Products were obtained only with the $V_{\gamma 2}$, $V_{\gamma 4}$ and $V_{\gamma 4}$ and $V_{\gamma 5}$ primers. The $V_{\gamma 3}$ and $J_{\gamma 1}$ primers and subcloning and sequencing of the products, are as described in the legend to Fig. 1. Other primers were: ACATTGGTACCGGCAAAAAAC($V_{\gamma 1}$), GGGGGGAATTCCCCTCACCCATATTTTCTT($V_{\gamma 2}$), CCAAAGAATTCTGTGTAGTTC($V_{\gamma 4}$) and TCCACTGGTACCGATTCCAAGAA($V_{\gamma 5}$). The $V_{\gamma 1}$ primer hybridizes both to the $V_{\gamma 1.1}$ and $V_{\gamma 1.2}$ gene segments. The $J_{\gamma 1}$ primer hybridizes to all four known J_γ gene segments.

FIG. 3 Junctional sequences of δ-chain rearrangements in IEL. *a*, Rearrangements involving $J_{\delta1}$. *b*, Rearrangements involving $J_{\delta2}$. *c*, Peptide sequences encoded by IEL δ junctions. Nucleotides between V_δ and J_δ germline sequences were assigned to $D_{\delta1}$ or $D_{\delta2}$ if two or more consecutive bases were present in the D_δ sequences. This was largely an arbitrary choice, as eight of the sixteen possible dinucleotides are present in either $D_{\delta1}$ or $D_{\delta2}$. The $V_{\delta6}$ sequences represent at least two different members of this subfamily. METHODS. Complementary DNA was prepared by reverse transcription of total cytoplasmic RNA (1 μg) from IEL of C57Bq/6J mice with a C_δ-specific primer[6]. After dilution, the cDNA was amplified by PCR with primers specific for $J_{\delta1}$ and $J_{\delta2}$ and one of seven V_δ primers in each reaction. The $V_{\delta1}$, $J_{\delta1}$, and $J_{\delta2}$ primers, and the subcloning and sequencing of the products, are as described in the legend to Fig. 1. Other primers used were: GGGGGATCCTGGCAGCCTCGTCTCCTTGG($V_{\delta2}$), TATTGGTACCGACAGGTTCCTCTTC($V_{\delta3}$), GTTCTGGTACCAACAGCAAGGAGGGCAGG($V_{\delta4}$), GGGGGTACCAGACAGTGGCAAGCGGCACTG($V_{\delta5}$), GGGGGATCCATCAGCCTTGTCATTTCA($V_{\delta6}$) and AGCCTCAGGGTACCCAACCCTG($V_{\delta7}$). The $V_{\delta6}$ primer hybrdizes to all members of the $V_{\delta6}$ subfamily described to date[9,21]. The $V_{\delta7}$ gene segment has been previously described as $V_{\delta2.3}$ (ref. 22).

Detection of refolding conformers of complement protein C9 during insertion into membranes

Roney O. Laine & Alfred F. Esser*

Laboratory for Structural Biology, Department of Comparative and Experimental Pathology, and Department of Biochemistry and Molecular Biology, University of Florida, Health Science Center, Gainesville, Florida 32610, USA

HUMAN complement protein C9 is a hydrophilic serum glycoprotein responsible for efficient expression of the cytotoxic and cytolytic functions of complement. It assembles on the surface of a target cell together with C5, C6, C7 and C8 to form the membrane attack complex (MAC) and therefore has to change structure to become an integral membrane protein[1–7]. As the protein assumes a stable structure in an aqueous environment, the question arises as to how it can enter the hydrophobic interior of a membrane. During MAC assembly C9 polymerizes into a circular structure, termed poly(C9) (ref. 8), which is responsible for the cylindrical electron microscopic appearance of the MAC. The suggestion has been made that C9 must at least partly unfold in order to enter a membrane[7–11] and also that polymerization of the molecule is intimately linked to insertion and cytotoxicity[11–13]. The extent of unfolding and the mechanism of polymerization are not understood, nor is it known precisely which parts of the molecule participate in the proposed structural changes. We have been able to capture refolding C9 conformers during membrane insertion with the help of sequence-specific anti-peptide antibodies. Some of these antibodies inhibit C9-mediated haemolysis but not C9 polymerization, while others have the opposite effect. This suggests that the two processes are independent.

We have previously described[9,14] evidence that C9 shares certain features with many other soluble proteins that insert spontaneously into membranes, such as colicins[15], lytic peptides[16,17], and precursor proteins[18–20] that are synthesized in the cytoplasm but are destined for location in specific organelles. Although the experimental evidence for the generation of intermediates during the insertion of precursor proteins, colicins, and C9 into membranes is good, it is frequently circumstantial: for instance, resistance to proteolysis. It is desirable, therefore, to have probes that can recognize refolding conformers directly when a water-soluble protein changes to its membrane-associated structure. We reasoned that the fine specificity of antibodies for differences in protein structures could provide such tools. As it is highly unlikely, however, that one could prepare specific immunogens from native C9 to generate antibodies against conformers of unknown structure, we prepared antibodies against sequence-specific peptides.

Twelve peptides were selected that might represent sequence regions in human C9 which are either important for functional activity or for the structural changes associated with functional activity. A more detailed discussion of why these particular peptides were chosen will be presented elsewhere. Here we describe the results that we have obtained with polyclonal antibodies raised in rabbits against eight peptides. Figure 1*a* and *b* shows the location of the peptides within the amino-acid sequence of human C9 and demonstrates that all of them recognize C9 on an immunoblot. When more specific sandwich enzyme-linked immunosorbent assays (ELISA) were performed, however, it became clear that only three antibodies, anti-(371–380), anti-(400–414) and anti-(509–517), recognized monomeric native C9 when captured by a monoclonal antibody (mAb) (Fig. 1*c*). Lack of recognition by the other antibodies was not caused by steric hindrance or occlusion of the binding site by the capturing antibody because the results were identical when either mAb-42 or mAb-47 were used. The former recognizes an epitope that includes amino acids 412–426 and the latter an epitope containing amino acids 29–34 (ref. 11). None of the antibodies reacted with other terminal complement proteins (data not shown).

To test whether any of these antibodies would recognize C9 when part of the MAC, we used flow cytometry to measure their

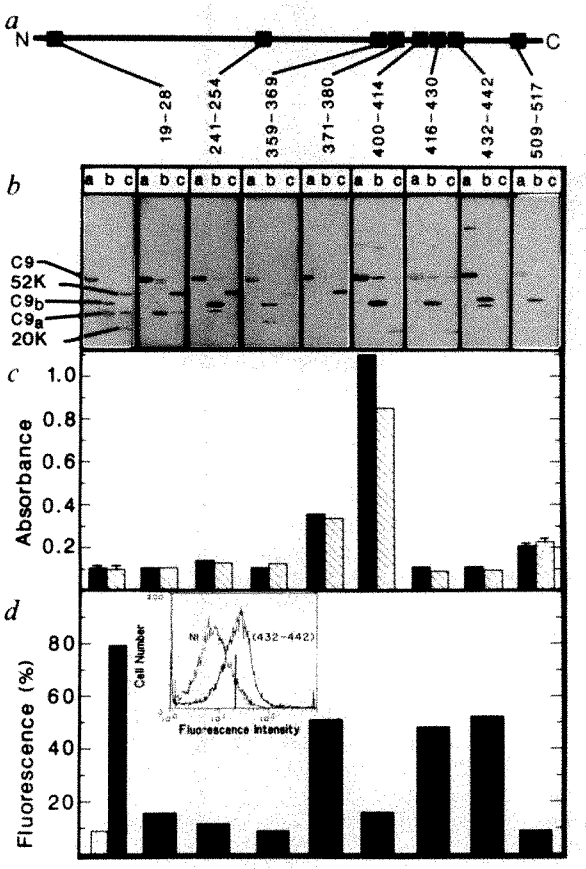

FIG. 1 Characterization of rabbit antibodies directed against C9-sequence specific peptides. *a*, Location of the selected peptides along the primary sequence of C9. *b*, Epitope mapping of the different antibodies by immunoblotting on whole C9 (lanes a) and fragments derived from limited proteolysis with α-thrombin (lanes b) or trypsin (lanes c). Far left panel shows a Coomassie blue staining of C9 and its fragments after transfer to a nitrocellulose membrane. *c*, Recognition of native C9 by anti-peptide antibodies in a 'sandwich' ELISA. Microtitre wells were coated with either monoclonal antibody mAb-42 (solid bars) or mAb-47 (hatched bars) to capture native C9 and binding of the anti-peptide antibodies was determined by ELISA. Far left panel shows binding of non-immune IgG to C9. *d*, Recognition of membrane-bound C9 by anti-peptide antibodies as measured by flow cytometry. A 'gate' was set at channel 20 and fluorescence recorded in channels 21–1000 is indicated for each anti-peptide. Far left panel shows results obtained with non-immune IgG (hatched bar) or polyclonal anti-C9 IgG (solid bars). Inset shows the autofluorescence of ghosts incubated with non-immune (NI) IgG contained in channels 1–20; specific binding of anti-peptide (432–442) shifts fluorescence to higher channels.

METHODS. Polyclonal rabbit anti-peptide antisera were elicited by immunization with peptides coupled to keyhole limpet haemocyanin, and monospecific IgG was isolated by immunoaffinity chromatography on solid phase peptides[16,17]. C9 and proteolytic fragments were produced as described, and immunoblotting and sandwich ELISAs were performed using standard techniques[16,17]. A Becton-Dickson FACS analyser was used for flow cytometry. Complement-lysed ghosts were prepared[21,22], mixed with individual anti-peptide antibodies, followed by addition of fluoresceinated IgG specific for rabbit IgG, and then analysed for ghost-associated fluorescence.

binding to complement-lysed erythrocyte ghosts which carried the MAC. Again, three antibodies were found that bound to ghosts (Fig. 1*d*). Unlike anti-(371–380), however, which also recognizes native C9 as already described, the other two, anti-(416–430) and anti-(432–442), were incapable of recognizing native C9, whereas anti-(400–414) and anti-(509–517), which detect native C9, had no affinity for membrane-bound C9. When C9 is part of the MAC on a target cell it is thought to be polymerized into poly(C9) (refs 7, 21). Poly(C9) can be produced *in vitro* by incubation of C9 with $ZnCl_2$[12,22]. When binding of anti-peptide antibodies to Zn-polymerized C9 was tested using a sandwich ELISA, only those antibodies that reacted with membrane-bound C9 also recognized poly(C9) (data not shown). We have therefore successfully produced antibodies which detect either native or membrane-bound C9.

The eight polyclonal anti-peptide antibodies were tested for their effect on C9-mediated lysis of antibody-sensitized erythrocytes carrying the earlier acting complement proteins C1–C8 (EAC1-8). Addition of C9 to a suspension of EAC1-8 cells elicits an immediate decrease in turbidity caused by haemolysis of the cells, and the time required to lyse 50% of the cells ($t_{50\%}$) can easily be monitored (Fig. 2*a*, inset). Despite the high affinity of C9 for EAC1-8 ($K_d < 10^{-11}$ M) (ref. 23), it is clear that anti-(416–430) and anti-(432–442) antibodies increased $t_{50\%}$ significantly, whereas anti-(371–380) and anti-(509–517) had a slight effect on haemolysis (Fig. 2*a*). The former two antibodies are those that recognized membrane-bound C9 and also poly(C9). Because of this specificity it was of interest to evaluate the effect they might have on the formation of poly(C9). Polymerization was triggered by incubation of monomeric C9 with a 17-fold molar excess of $ZnCl_2$ and the reaction was monitored by perpendicular-light scattering. In contrast to what was observed before, the two antibodies that inhibited haemolysis, anti-(416–430) and anti-(432–442), retarded aggregation only very slightly (Fig. 2*b*). Even more surprising, however, was the observation that two antibodies, anti-(19–28) and anti-(241–254), which had no detectable affinity for native or membrane-bound C9 or poly(C9) (see Fig. 1), inhibited polymerization very strongly. Poly(C9) formation was also suppressed by anti-(509–517), revealing that this reaction can be inhibited by antibodies directed against the amino and carboxy terminals and the middle section of the molecule.

When C9 aggregates it loses its haemolytic activity[12]. We have verified this observation. When the different antibodies were evaluated for their influence on haemolytic activity of C9 in response to Zn-mediated polymerization, the results mirrored those obtained by monitoring aggregation directly (data not shown). In Table 1 we summarize the recognition patterns of all eight anti-peptide antibodies and their functional effects. We wish to emphasize the fact that we have produced two sets of antibodies, one comprised of anti-(19–28) and anti-(241–254) which inhibits poly(C9) formation but not haemolysis, and one comprised of anti-(416–430) and anti-(432–442) which inhibits

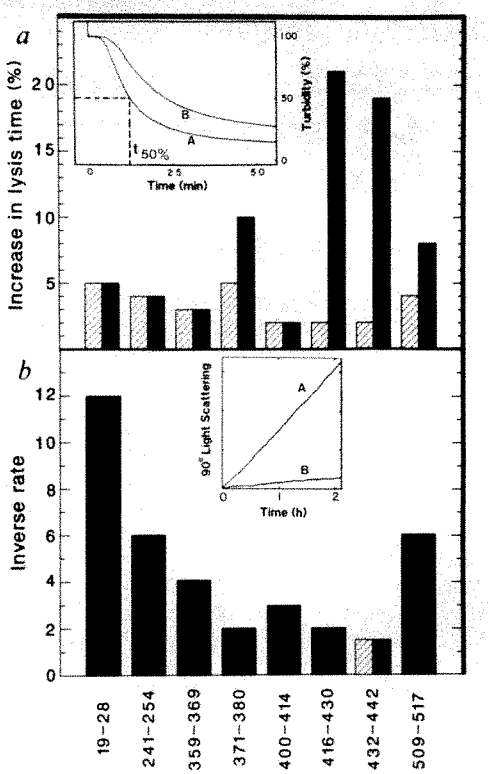

FIG. 2 Inhibition of C9-mediated lysis of EAC1-8 cells and of Zn^{2+}-catalysed polymerization of C9. *a*, Inset shows decrease in turbidity (curve A) caused by lysis of EAC1-8 cells effected by addition of C9 at time 0. Time required to achieve 50% lysis is indicated as $t_{50\%}$ and inhibition of lysis by curve B. The increase in $t_{50\%}$ values effected by anti-peptide IgG is displayed as solid bars and by pre-immune IgG as hatched bars. *b*, Inset shows increase in 90°-light scattering caused by formation of C9 polymers during incubation of C9 with Zn^{2+} (curve A); inclusion of anti-peptide (19–28) prevents polymerization of C9 (curve B). Inhibition of polymerization by the different antibodies (solid bars) or by non-immune IgG (hatched bar) is plotted as the inverse rate of polymerization for each antibody.
METHODS. EAC1-8 cells were prepared as described[16,22] and lysis mediated by C9 was monitored by forward light scattering[16]. Polymerization of C9 (6 μM) catalysed by $ZnCl_2$ (0.1 mM) was performed as described[12] and the reaction was monitored by 90°-light scattering at 320 nm in a fluorometer. The inverse reaction rate was calculated from the initial slope between 0 and 30 min.

haemolysis but not polymerization, strongly suggesting that the two reactions are mutually independent.

To further evaluate the C9 conformer that could act as an antigen for anti-(19–28), we made use of the antibody-binding capacity of protein A coupled to Sepharose beads. These beads were first used to capture the different anti-peptide antibodies and then, after washing and resuspension, monomeric C9 (con-

taining ^{125}I-labelled C9 as a tracer) was added and the mixture incubated with or without a 17-fold molar excess of $ZnCl_2$. As anti-(19–28) did not react with monomeric or poly(C9), we reasoned that a different C9 conformer must have formed during polymerization which was able to bind to the solid-phase antibody. The results shown in Fig. 3*a* verified our expectation: the amount of radioactive C9 captured by the beads increased significantly only when $ZnCl_2$ was present in the mixture. Analysis of the bound ^{125}I-labelled C9 by SDS-PAGE and autoradiography confirmed that it was not present as SDS-resistant poly(C9) (data not shown). In contrast to anti-(19–28), another antibody, anti-(509–517), which also inhibited poly(C9) formation, did not capture more radioactive C9. We conclude from these results that the latter antibody has a small inhibitory effect because it binds already to native monomeric C9 (see also Fig. 1*c*) and thereby inhibits aggregation, whereas anti-(19–28) suppresses aggregation because it traps a transient C9 conformer.

When the same experimental protocol was used with anti-(432–442) bound to protein A-Sepharose, it also precipitated significantly more ^{125}I-labelled C9 when polymerization was allowed. This result was not expected because the antibody does not have any influence on Zn-catalysed C9 aggregation (Fig. 2*b*). Because the antibody retarded haemolysis, however, (Fig. 2*a*) the combined data would be consistent with the notion that during poly(C9) formation and during haemolysis, the same C9 conformer was formed. To test this possibility, we modified the Protein-A-Sepharose experiment in such a way that recognition of the same conformer by different antibodies could be tested. Solid phase anti-(19–28) was used to trap the (unlabelled) C9 conformer and then binding of a second radioiodinated anti-peptide IgG to the trapped conformer was measured. Only anti-(371–380), which recognizes all forms of C9 (Table 1), associated with the trapped conformer, whereas anti-(416–430) and anti-(432–442) did not (Fig. 3*b*). As we will report elsewhere, some of the antibodies that do not recognize native or membrane-bound C9 also accumulate during lysis on target cells. These results indicate that several different conformers are formed during C9 aggregation *in vitro* and on membranes during haemolysis. The existence of such transient intermediates was originally predicted by Boyle and Borsos[3], who described tham as C9$^{'doomed'}$ and C9$^{'inserted'}$. We have now been able to provide direct experimental proof for these predictions. Our results do not support models which link haemolysis directly to C9 polymerization.

In summary, we have found several anti-peptide antibodies which do not recognize soluble native C9 or the final membrane-bound form. They do, however, capture C9 conformers that are formed during membrane insertion of C9, as well as conformers formed during *in vitro* polymerization. This shows that anti-peptide antibodies specific for refolding conformers can be generated and that such antibodies are very useful tools to unravel some of the intricacies of protein reactions on membranes. This approach may also be useful for study of protein folding and to provide information on protein conformers in general. □

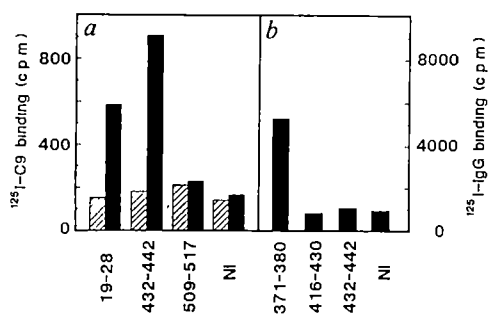

FIG 3 Detection of C9 conformers. *a*, Binding of C9 to solid-phase antipeptide IgG during Zn^{2+}-catalysed C9 polymerization. Solid phase antipeptide IgG or non-immune (NI) IgG was first prepared by fixing antibody (1.5 mg) to a suspension of protein A-Sepharose 6MB beads (Sigma) in 70 μL buffer (10 mM Tris, 0.15 M NaCl, pH 7.3). After washing away unbound antibody, the beads were resuspended in 0.9 ml Tris buffer containing 0.1 mM $ZnCl_2$. Monomeric, ^{125}I-trace-labelled C9 (40 μg) was added and the mixture incubated for one hour with mixing. The beads were washed and the associated radioactivity was meaured (solid bars). Control samples (hatched bars) were treated identically, except $ZnCl_2$ was omitted during the incubation. *b*, Binding of two anti-peptide antibodies to a trapped C9 conformer captured by anti-(19–28) during Zn^{2+}-catalysed C9 polymerization. Anti-peptide (19–28) was bound to Protein A-Sepharose beads and incubated with unlabelled C9 in a $ZnCl_2$ containing Tris buffer as described before. After removing unbound antibody, ^{125}I-trace-labelled anti-peptide IgG or non-immune IgG was added and after one hour, bead-associated radioactivity was determined. All measurements shown in this figure are the means of triplicate determination.

Augmentation of cardiac calcium current by flash photolysis of intracellular caged-Ca^{2+} molecules

A. M. Gurney, P. Charnet*, J. M. Pye & J. Nargeot*

THE entry of calcium ions into cells through voltage-activated Ca^{2+} channels in the plasma membrane triggers many important cellular processes. The activity of these channels is regulated by several hormones and neurotransmitters, as well as intracellular messengers such as Ca^{2+} itself (for examples, see refs 1–9). In cardiac muscle, myoplasmic Ca^{2+} has been proposed to potentiate Ca^{2+} influx[1,7–9], although a direct effect of Ca^{2+} on these channels has not yet been demonstrated. Photosensitive 'caged-Ca^{2+}' molecules such as nitr-5, however, provide powerful tools for investigating possible regulatory roles of Ca^{2+} on the functioning of Ca^{2+} channels[10,11]. Because its affinity for Ca^{2+} is reduced by irradiation, nitr-5 can be loaded into cells and induced to release Ca^{2+} with a flash of light[10]. By using this technique we found that the elevation of intracellular Ca^{2+} concentration directly augmented Ca^{2+}-channel currents in isolated cardiac muscle cells

from both frog and guinea pig. The time course of the current potentiation was similar to that seen with β-adrenergic stimulation. Thus Ca^{2+} may work through a similar pathway, involving phosphorylation of a regulatory Ca^{2+}-channel protein. This mechanism is probably important for the accumulation of Ca^{2+} and the amplification of the contractile response in cardiac muscle, and may have a role in other excitable cells.

Although a few experiments have been attempted with isolated ventricular cells from guinea-pig heart, most have been with frog atrial cells, from *Rana temporaria* or *Rana esculenta*, because the sarcoplasmic reticulum in these cells is less well developed[12]. The whole-cell tight-seal recording technique was used to voltage clamp cells, and nitr-5 (2 mM) was incorporated intracellularly by its inclusion in the solution filling the patch pipettes[10]. In most experiments, nitr-5 was the only Ca^{2+} chelator present, and $CaCl_2$ was added to set the pre-flash internal free-Ca^{2+} concentration at ~145 nM. Light flashes, delivered from a xenon short-arc flashlamp, were focused onto cells through the epifluorescence port and objective of an inverted microscope. A single flash was estimated[10] to raise the concentration of free Ca^{2+} to ~1 μM. Because the light spot was restricted to the cell and <200 μm of the pipette tip, unphotolysed solution from the pipette would have rapidly returned the Ca^{2+} concentration to the pre-flash level, probably within about 30 s (ref. 10).

A single light flash resulted in strong enhancement of the current carried through Ca^{2+} channels by either Ca^{2+} or Ba^{2+} (Fig. 1*a*, *b*). In frog atrial cells, the flash increased the Ba^{2+} current amplitude by a factor of 2.6 ± 0.3 (mean ± s.e.m.; $n = 5$), whereas Ca^{2+} currents were increased by a factor of 2.0 ± 0.2 ($n = 3$). The Ca^{2+} current was similarly potentiated in guinea-pig ventricular cells (Fig. 1*c*), with a mean increase in peak amplitude of 1.6-fold ($n = 2$). This effect was reproducible and fully reversible, with the current returning to the pre-flash level in 5–10 min (results not shown). Current potentiation reflected the rise in intracellular Ca^{2+} because flashes had no effect (1) when nitr-5 was replaced with EGTA (1–10 mM; results not shown), or (2) when $CaCl_2$ was omitted and an excess of the photostable chelator BAPTA (10 mM), which binds Ca^{2+} rapidly and tightly[11], was added to the pipette (Fig. 1*c*). Changes in pH were unlikely to have been responsible for the potentiation seen with nitr-5, because nitr-5 has a low affinity for protons at physiological pH[11,13], and therefore should not have bound to protons when Ca^{2+} was released. If, on the contrary, raising the Ca^{2+} concentration caused a fall in intracellular pH, as previously shown in the mammalian heart[14], then this would have been expected to block Ca^{2+} channels[15]. Furthermore, changes in pH should have been quickly buffered by HEPES (10 mM) included in the pipette. Finally, flash photolysis of intracellular caged cyclic GMP (≤250 μM), which releases protons as a by-product, has been previously shown to have no effect on Ca^{2+} currents in the frog atrium[16]. Thus we conclude that the potentiation of the Ca^{2+} current by flash photolysis of caged Ca^{2+} arose as a result of released Ca^{2+}.

Figure 2*a* compares the current–voltage relationship of peak Ca^{2+}-channel currents, recorded from a frog atrial cell before and after nitr-5 photolysis. Frog atrial[17] and guinea-pig ventricular[18] cells display two components of Ca^{2+} current: from holding potentials of −80 to −100 mV, depolarizing steps of increasing amplitude activate first a low-threshold component, which peaks at around −40 mV, and then a high-threshold component that begins to activate at around this voltage. In a cell with a negligible low-threshold current (Fig. 2*a*), the peak current amplitude was enhanced by Ca^{2+} release induced by a flash at all potentials. At potentials too negative to activate high-threshold current, however, the flash had no measurable effect. This implies that the increased current was carried through high-threshold Ca^{2+} channels. In agreement with this, both the pre-flash and flash-induced currents were blocked by low (<100 μM) concentrations of Cd^{2+} (Fig. 2*b*). Thus the increase

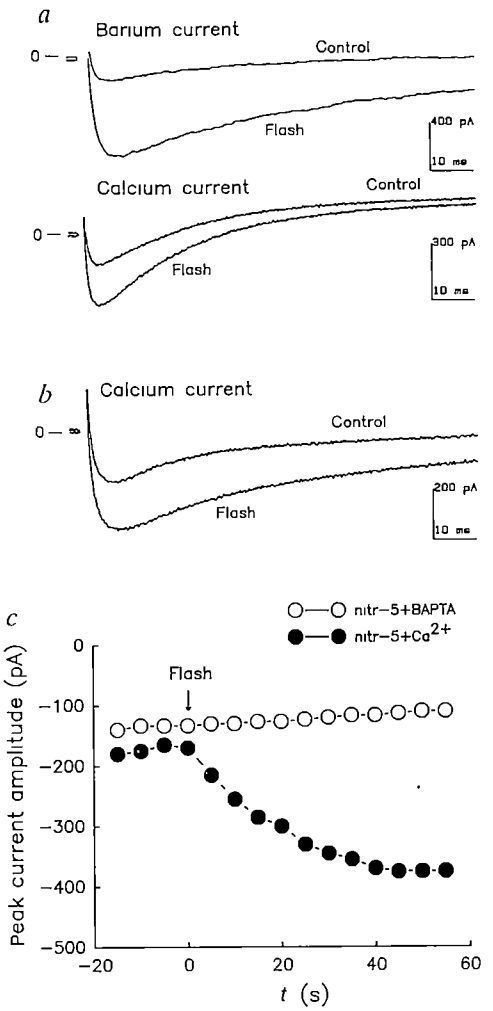

FIG 1 Flash photolysis of caged Ca^{2+} augments Ca^{2+}-channel currents in frog atrial (*a*) and guinea-pig ventricular (*b*) cells Currents evoked by voltage steps to +10 mV from a holding potential of −80 mV (frog) or −50 mV (guinea pig) before a flash (control) and at the peak of the response Blanked periods indicate amplifier saturation from capacity transients Leak currents are not subtracted *c*, Effect of buffering intracellular Ca^{2+} Data from two frog atrial cells stimulated at 0 2 Hz. Pipettes contained either 2 mM nitr-5 with added Ca^{2+} (1 mM) (●), or 2 mM nitr-5 with 10 mM BAPTA (○). Current amplitude is measured as difference between peak current and steady-state current at end of 150-ms pulse

METHODS Frog atrial cells were isolated by a similar method to that described in ref. 28. In brief, tissue fragments were incubated for 15 min in a solution containing (mM). NaCl, 109, KCl, 2 5, $MgCl_2$, 7 5, $CaCl_2$, 0 15, $NaHCO_3$, 2, glucose, 10, HEPES, 10, pH 7 4. They were then incubated for 1 h in the same solution but without $NaHCO_3$ and containing pyruvate (10 mM), taurine (10 mM), trypsin (500 international unit (IU) ml^{-1}; type III, Sigma), collagenase (200 IU ml^{-1}, type 1A, Sigma), protease (2 IU ml^{-1}; type XIV, Sigma) and bovine serum albumin (BSA, 0 05% fraction V, Sigma) Finally, fragments were incubated for at least 3 h in the first solution with 0.05% BSA Guinea-pig ventricular cells were isolated as described[29] For recording, frog cells were bathed in (mM) NaCl, 109, KCl, 2 5, $MgCl_2$, 2 5, $CaCl_2$ (or $BaCl_2$), 5, $NaHCO_3$, 2, glucose, 10, HEPES, 10, tetraethylammonium, 5, tetrodotoxin, 0 001, pH 7 4. Pipettes (2–6 MΩ) usually contained (mM) CsCl, 110, nitr-5, 2; $CaCl_2$, 1; ATP-Mg, 1, GTP-Na, 0 5, phosphocreatine, 5, pH 7 2 All but 1–6 MΩ of series resistance was compensated Similar solutions were used for guinea-pig cells, except that extracellular NaCl and intracellular CsCl were increased to 130 mM and extracellular $CaCl_2$ was reduced to 1 mM The flashlamp (Chadwick Helmuth, El Monte, California) discharged 230 J of stored energy in <1 ms over a broad spectrum, which was filtered to remove wavelengths <300 nm before focusing Changes in Ca^{2+} concentration were estimated from flash-induced changes in absorbance of test droplets (~250 μm diameter) of nitr-5 solution placed in the set-up as previously described[10]. All experiments performed at room temperature (~22–24 °C)

in current induced by a flash must have been caused by an increase in Ca^{2+}-channel activity.

The flash-induced current developed slowly, taking many seconds to reach the maximal effect (see Figs 1*c* and 2*b*). This did not, however, reflect the speed of Ca^{2+} release from nitr-5, because this occurs with a sub-millisecond time constant[11]. It was more likely to reflect intracellular events coupling the rise in Ca^{2+} concentration to current potentiation. Further experiments were thus performed on frog atrial cells to determine the possible nature of these intracellular events. The slow increases in the Ca^{2+}-channel current were reminiscent of responses to β-adrenergic agents such as isoprenaline, which act primarily through cyclic AMP-dependent phosphorylation of regulatory channel proteins[19]. Perhaps channels could also be phosphorylated by Ca^{2+}-dependent protein kinases, which are known to be present in heart muscle[20]. Thus, it was of interest to compare directly the time course of current potentiation induced by a flash with that induced by isoprenaline. Figure 3*a* shows such a comparison made in a single cell; an application of isoprenaline (10 μM for 10 ms) increased the Ca^{2+} current by a factor of 5.1±0.8 (mean±s.e.m; $n=10$). The increase in response to isoprenaline occurred with a delay that was not apparent in the response to the flash. Ignoring this, however, isoprenaline produced an increase in the current over a similar time course to flash-induced Ca^{2+} release. The delay presumably reflected the diffusion time of isoprenaline from the pipette to the cell and the activation of adenylate cyclase, because it can be removed if the adrenergic receptors are by-passed by applying cAMP directly in cells, using flash-photolysis of caged cAMP[16,21]. The responses to a flash and to isoprenaline also appeared to follow a similar time course in guinea-pig ventricular cells.

If the transient release of Ca^{2+} causes phosphorylation of the same protein as does isoprenaline, then channels maximally activated by isoprenaline should not respond to a flash[22]. Figure 3*b* shows that when a flash was presented at the peak of the response to isoprenaline, it did not augment the current any further. A similar result was obtained when the stimuli were applied in the reverse order, with a flash reducing the effectiveness of isoprenaline (results not shown). Thus there seems to be a common step in the pathways leading to the Ca^{2+}-current potentiation by flash-induced Ca^{2+} release and isoprenaline. If Ca^{2+} in some way triggers channel phosphorylation, then the response to a flash should depend on the intracellular level of ATP, as shown for isoprenaline[22]. Indeed, if ATP-Mg was omitted from the pipette, the flash-induced Ca^{2+} release only increased currents by ~30% in frog atrial cells. The responses also showed 'rundown', in that flashes were less effective on the second and subsequent presentations. In the presence of ATP, however, repeated flashing (or isoprenaline application) at 5–10 min intervals produced almost identical increases in current.

Does this phenomenon have a physiological role? It could underlie the facilitation of the Ca^{2+} current observed in mammalian[7,9,23,24] and frog[8] heart cells during repetitive stimulation. This is associated in frog atria with an increase in contractile force[8,25]. Stimulation-dependent current potentiation requires Ca^{2+} influx, because it is suppressed when other ions carry the current[7,8], and it occurs over a similar time course to the potentiation described here. This facilitation is also blocked by isoprenaline[7]. A similar Ca^{2+}-dependent facilitation mediates the enhancement of the cardiac Ca^{2+} current produced by low concentrations of cardiac glycosides[1], and may have additional roles in maintaining Ca^{2+}-channel activity[9]. Thus positive regulation of the Ca^{2+} current by intracellular Ca^{2+} could provide a general mechanism for accumulating Ca^{2+} and amplifying the contractile response in cardiac muscle.

To prevent intracellular Ca^{2+} overloading, sufficient increases in cytoplasmic Ca^{2+} concentration might be expected to eventually inactivate Ca^{2+} channels[2–6]. In many previous experiments, inactivation may have been large enough to mask the facilitatory effects of Ca^{2+} (ref. 7). Nevertheless, the predominant effect of flash-induced Ca^{2+} release was to potentiate the Ca^{2+}-channel current. In frog cells, inactivation was usually seen only when currents were already potentiated by isoprenaline (Fig. 3*b*). By contrast, the flash-induced potentiation in guinea-pig cells was preceded by a small (<10%) and short-lived (<10 s) depression of the Ca^{2+}-current amplitude. These findings are consistent with the original proposal of Marban and Tsien[1] that relatively small rises in myoplasmic Ca^{2+} concentration facilitate Ca^{2+} influx, whereas larger rises oppose it. Unfortunately, the present experiments do not elucidate the absolute concentrations at which Ca^{2+} produces the two effects. Our estimate of 1 μM as the concentration of Ca^{2+} generated by a flash may not reflect the true change detected by the cells. The transient release of Ca^{2+} may have been reduced if cell absorbance was significant and/or Ca^{2+} was rapidly bound by contractile proteins. The transient increase in Ca^{2+} would also be distorted by the sarcoplasmic reticulum, which releases Ca^{2+} in response to a rise in Ca^{2+} concentration[26], and is a particular problem when studying guinea pig cells. A quantitative description of Ca^{2+} regulation of Ca^{2+} channels will therefore require the intracellular concentration of free Ca^{2+} to be measured at the same time as it is changed.

The present study indicates that sarcoplasmic Ca^{2+} augments Ca^{2+}-channel currents by activating a protein kinase. The most

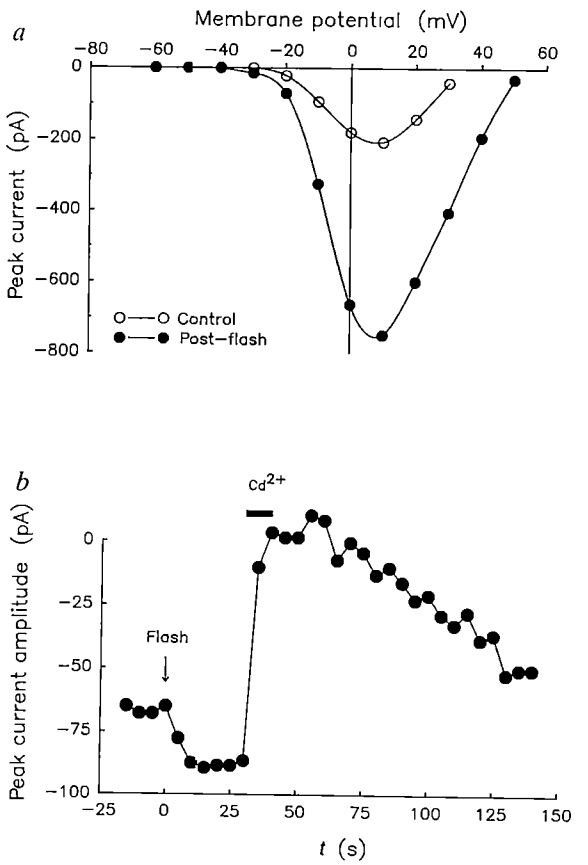

FIG 2 Voltage and Ca^{2+} dependence of the flash-induced current in frog atrial cells. *a*, Voltage dependence of peak Ba^{2+} current during 200-ms voltage steps, from a holding potential of −80 mV to various test potentials Currents recorded before the flash (O) and at the peak of the flash response (●) *b*, Peak amplitude of Ca^{2+} current evoked by steps to +10 mV from a holding potential of −80 mV at 0.2 Hz After a flash (indicated by an arrow), delivered at $t=0$, peak current amplitude increased Bathing solution containing 100 μM $CdCl_2$ (application indicated by a bar) was applied to the cell during the flash response by pressure ejection (7–20 kPa) from a micropipette positioned ~100 μm away. This blocked both the pre-flash and flash-induced current.

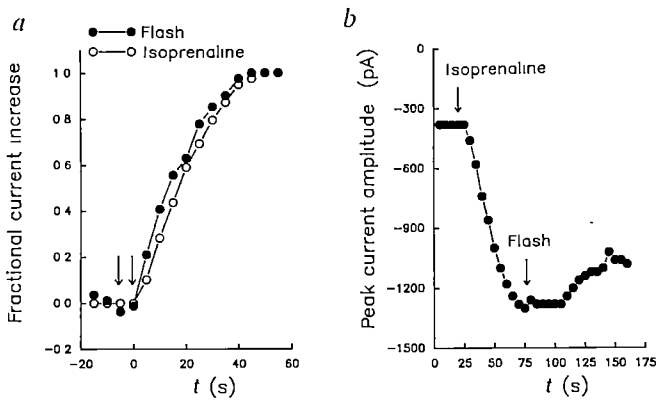

FIG. 3 Comparison of the increases in current induced by a flash and by 10 ms exposure to isoprenaline (10 μM) in frog atrial cells Currents elicited by depolarizing steps to +10 mV from a −80 mV holding potential at 0 2 Hz Isoprenaline application is indicated by the arrow furthest to the left and flashes by the arrow furthest to the right *a*. Time course of potentiation The current was first increased by presenting a flash to the cell (●), allowed to recover, and then stimulated again by applying isoprenaline (○). The increase in peak current amplitude at each voltage step is plotted as a fraction of the maximum increase observed in response to either stimuli. The current recorded immediately before the first detectable change in amplitude is plotted as the value at $t=0$ *b*, Blockade of the flash-induced current potentiation by isoprenaline. Peak current amplitude was first increased by applying isoprenaline A flash was then presented at the peak of the isoprenaline response. No further increase was observed.

likely candidate is a Ca^{2+}- and calmodulin-dependent protein kinase[1]. This could promote phosphorylation by interacting with the cAMP cascade. Alternatively, the kinase could directly phosphorylate the channel. Support for this idea comes from a recent report that shows that dihydropyridine-sensitive Ca^{2+} channels in cell-free membrane patches from GH3 cells are modulated by Ca^{2+}-calmodulin-dependent phosphorylation[27]. The approach that we used to study Ca^{2+} regulation of Ca^{2+} channels is one that can be employed to directly investigate these possibilities. □

Differential activation by atrial and brain natriuretic peptides of two different receptor guanylate cyclases

Ming-shi Chang, David G. Lowe, Martyn Lewis, Renate Hellmiss, Ellson Chen & David V. Goeddel

Department of Molecular Biology, Genentech Inc., 460 Point San Bruno Boulevard, South San Francisco, California 94080, USA

ALPHA atrial natriuretic peptide (α-ANP) and brain natriuretic peptide are homologous polypeptide hormones involved in the regulation of fluid and electrolyte homeostasis[1,2]. These two natriuretic peptides apparently share common receptors and stimulate the intracellular production of cyclic GMP as a second messenger[1]. Molecular cloning has defined two types of natriuretic peptide receptors: the ANP-C receptor of relative molecular mass (M_r) 60–70,000 (60–70 K), which is not coupled to cGMP production and may function in the clearance of ANP (refs 3, 4) and the ANP-A receptor of M_r 120–140 K, which is a membrane form of guanylate cyclase in which ligand binding to the extracellular domain activates the cytoplasmic domain of the enzyme[5,6]. Here we report the cloning and expression of a second human natriuretic peptide-receptor guanylate cyclase, the ANP-B receptor. The ANP-B receptor is preferentially activated by porcine brain natriuretic peptide rather than human α-ANP, whereas the ANP-A receptor responds similarly to both natriuretic peptides. These observations may have important implications for our understanding of the central and peripheral control of cardiovascular homeostasis.

In the course of screening a human placental complementary DNA library for ANP-A receptor clones[5], we identified a cDNA encoding a protein homologous to the ANP-A receptor, which we have termed the ANP-B receptor. The nucleotide- and predicted amino-acid sequence of the ANP-B receptor is shown in Fig. 1. This sequence probably represents a nearly complete transcript as northern analysis indicates that human brain ANP-B receptor messenger RNA is ~4,000 nucleotides long (data not shown). In the 283 nucleotides 5′ of the putative translation initiation codon there are termination codons in all three reading frames. The translation initiation codon defines the beginning of a 1,048 amino acid open reading frame with an N-terminal hydrophobic signal peptide[7] of 22 amino acids. Beginning with residue Arg+1, the mature ANP-B receptor amino-acid sequence has a predicted M_r of 114,952 with a 442-amino-acid extracellular domain containing 7 potential N-linked glycosylation sites and 6 cysteine residues. Hydropathic analysis predicts a transmembrane domain from residues 434 to 456 followed by an Arg–Lys stop transfer sequence[8]. The predicted cytoplasmic domain extends for 569 amino acids and has one potential N-linked glycosylation site and 9 cysteine residues.

The predicted amino-acid sequences of the human ANP-B receptor, the human ANP-A receptor[5] and the bovine ANP-C receptor[3] are compared in Fig. 2. The extracellular domain of the ANP-B receptor has 44% amino-acid identity with the ANP-A receptor and 30% identity with the ANP-C receptor, whereas the ANP-A receptor has 33% identity with the ANP-C receptor[5,6]. There is one region that is more highly conserved in all three molecules: residues 75–102 of the ANP-B receptor have 79% sequence identity with the ANP-A receptor and 71% identity with the ANP-C receptor. It is possible that the greater similarity found in this region may be critical in the recognition of natriuretic peptides. This region also contains one of the two cysteine residues that are conserved between all three receptors, ANP-B receptor residues Cys 79 and Cys 205. The structural and functional homology (see below) of the ANP-B, ANP-A,

and ANP-C receptors defines a gene family of natriuretic-peptide receptors.

There is 74% identity between the intracellular domains of the ANP-B receptor (568 residues) and the ANP-A receptor (566 residues). This region may be subdivided into two domains based on the previously described homology to protein kinases and to a subunit of the soluble guanylate cyclase (refs 5, 6, 9). The kinase homology domain of the ANP-B receptor (Fig. 2, residues 495–773) is 63% identical to the ANP-A receptor kinase homology domain. Several observations suggest a role for this region in the regulation of ANP-B and ANP-A receptors. A direct effect of amiloride, a potent diuretic, on a 130 K α-ANP-receptor guanylate cyclase from adrenal glomerulosa has been described in which there is a change in receptor conformation and a lowering of the K_d for α-ANP (refs 10, 11). Amiloride is also a competitive inhibitor of ATP binding to the active site of protein kinases[12,13]. In addition, there is an effect of ATP, or non-hydrolysable ATP analogues, on increasing the V_{max} of membrane guanylate cyclase in response to α-ANP stimulation[14,15]. These data indicate that the kinase homology domain of the ANP-B and ANP-A receptors may define the structural basis for a regulatory allosteric nucleotide-binding site[11,14].

The 252 residues at the C-terminus of the ANP-B receptor are 88% identical to the ANP-A receptor sequence. This cyclase homology region[5,6] represents the most highly conserved domain between the ANP-B and ANP-A receptors. There is 42% identity between this region[5,6] and a subunit of soluble guanylate cyclase

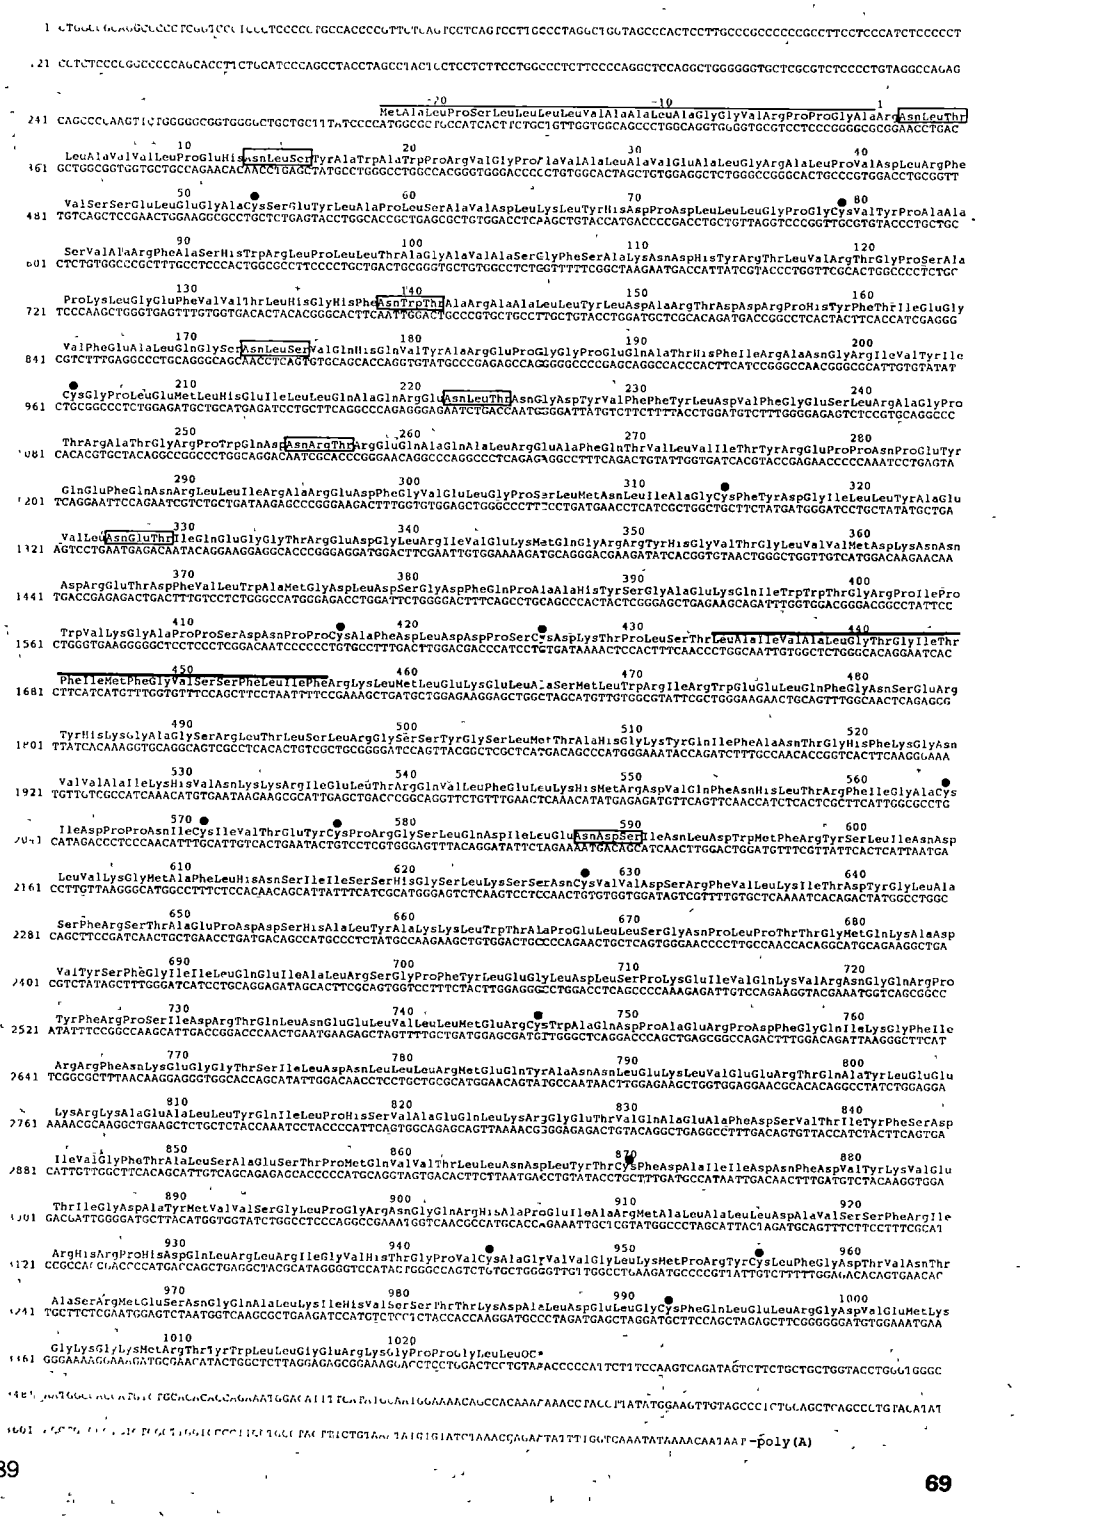

FIG 1 Nucleotide sequence and deduced amino-acid sequence of the human ANP-B receptor. Nucleotides are numbered at the beginning of each line and amino acids are numbered above the sequence. Nucleotides 1–911 are from a genomic clone; nucleotide 912 to the 3′ end are from a fetal brain cDNA clone. The 22-residue signal sequence is overlined with a thin line, and the predicted first residue of the mature protein is indicated by +1. The transmembrane domain is indicated by the thick black line over amino acids 434–456. Potential N-linked glycosylation sites are shown by boxes around Asn-X-Ser/Thr tripeptides, where X denotes any amino acid. Cysteine residues are indicated by a solid dot above the sequence.

METHODS A partial cDNA clone of the human ANP-A receptor was used as a probe to screen a human placenta cDNA library in λgt10 (see ref. 5). Of 16 hybridizing clones chosen for sequence analysis, one clone (16B) was found to encode an ANP-A receptor-related protein which was named the ANP-B receptor. The 16B cDNA clone was used as a probe to screen λgt10 cDNA libraries of human fetal brain[22], pituitary[20], terminal ileum (J. McLean, unpublished data) and porcine atrium[23]. Several partial cDNA clones but no full-length clones of the ANP-B receptor were isolated from these libraries. To obtain the full-length ANP-B coding sequence, a human genomic library[28] was screened with 200 base pairs of 5′-most ANP-B cDNA to isolate an ANP-B genomic clone. Genomic DNA sequence extending 1 kilobase 5′ of the longest cDNA clone was determined and used to design oligonucleotides for polymerase chain reaction (PCR)[30] amplification of specifically primed cDNA from human glioma cell RNA. Cloning and sequencing of PCR reaction products confirmed our assignment of the ANP-B receptor coding sequence.

from bovine lung (ref. 16) and ~30% identity to a twice-repeated motif in the bovine adenylyl cyclase[17]. The structural homology and functional similarity between these proteins, that is catalysis of cyclic-3′, 5′-nucleotide monophosphate formation, indicates that this conserved region will contain the active site of these enzymes.

To examine the biochemical properties of the ANP-B receptor, we constructed an expression vector in which the coding sequence was placed under the transcriptional control of the

FIG. 2 Homologies of the ANP-B receptor The predicted amino-acid sequence of the mature ANP-B receptor (ANP-B) is aligned with the human ANP-A receptor (ANP-A)[5] and bovine ANP-C receptor (ANP-C)[3] sequences. Gaps introduced for an optimal alignment are shown by dashes and amino acids identical in two or more of the aligned sequences are boxed. The transmembrane domain of ANP-B is shown by an overline (residue 434–456)

cytomegalovirus immediate-early promoter (Table 1, legend). The ANP-B expression vector was transfected into COS-7 cells in a transient expression assay and the detergent-solubilized guanylate cyclase activity of a membrane fraction was measured (Table 1). Cells transfected with the ANP-B expression vector have ~11-fold higher guanylate cyclase-specific activity than control cells, whereas cells transfected with an ANP-A receptor expression vector[5] have a sixfold higher guanylate cyclase-specific activity. Specific binding of ^{125}I-labelled human α-ANP and ^{125}I-labelled-porcine brain natriuretic peptide (pBNP) to transfected cells was determined in the presence or absence of unlabelled peptides Cells expressing either the ANP-B or ANP-A receptors specifically bound threefold more ^{125}I-labelled α-ANP each, and three- to fourfold more ^{125}I-labelled pBNP, respectively, than control cells (Table 1). Note that the specific activity of ^{125}I-labelled pBNP is threefold less than ^{125}I-labelled α-ANP (Table 1, legend).

Ligand-dependent activation of the cytoplasmic guanylate cyclase domains of the human ANP-B and ANP-A receptors was examined in transient expression whole-cell stimulation assays. Cells expressing the ANP-A receptor responded in the same way to stimulation by either α-ANP or pBNP, with a 1.5- to 2-fold increase in cGMP produced over control transfected cells (Fig. 3, *a* and *c*). Cells expressing the ANP-B receptor responded to α-ANP stimulation with a threefold increase in cGMP synthesized as compared to control transfected cells. Quite strikingly, pBNP gave a 9.7-fold increase in cGMP from the ANP-B receptor compared with pBNP-treated control transfected cells (Fig. 3*b*, *c*). The pBNP ligand is 6.4-fold more effective than α-ANP in the activation of ANP-B receptor guanylate cyclase activity. Human BNP is not yet commercially available for comparison with α-ANP in the whole-cell stimulation assays, and we note that there is only 70% identity between human and porcine BNP, as opposed to the high sequence conservation of α-ANP's between species[18]. Although comparison of the predicted amino-acid sequence from a partial porcine ANP-B receptor cDNA to the human ANP-B receptor reveals 99% identity for 736 residues (unpublished data), the response of these receptors to their homologous BNP ligands could be different. Nevertheless, the use of pBNP and α-ANP allows pharmacological discrimination of human ANP-A and ANP-B receptors through the magnitude of guanylate cyclase activation.

Screening of a variety of high complexity λgt10 cDNA libraries for ANP-B receptor (Fig. 1, legend) and ANP-A receptor[5] cDNA clones suggests differences in the tissue distribution of the mRNA for these two receptors. Whereas only ANP-A receptor cDNAs were cloned from a human kidney cDNA library[19] (complexity: 5×10^5 clones), cDNAs for both receptors were cloned from human pituitary[20] and placental[21] cDNA libraries. The isolation of only ANP-B receptor cDNAs from human fetal brain[22] (complexity: 1.5×10^6 clones), and porcine atrium[23] (complexity: 2.5×10^6 clones) cDNA libraries suggests that the ANP-B receptor is the predominant natriuretic peptide-receptor guanylate cyclase in these two tissues. The isolation of a rat ANP-A receptor cDNA from a rat-brain library[6] would seem to indicate that this receptor is also present in the brain. Alternatively, this finding may represent a difference between human and rat for ANP-A receptor distribution. *In situ* hybridization with natriuretic peptide-receptor cDNAs should resolve the species-specific differences in expression of these receptors.

Previous biochemical evidence[24] had not suggested the presence of natriuretic peptide-receptor guanylate cyclase subtypes. The identification of two receptor guanylate cyclases, each with two natriuretic peptide ligands, reveals a hitherto unappreciated complexity to this system. It will now be possible to determine the role of each of the four possible receptor guanylate cyclase/ligand combinations in cardiovascular regulation. Our data on the activation of ANP-B and ANP-A receptor second-

TABLE 1 Particulate guanylate cyclase activity and natriuretic peptide binding of transfected COS-7 cells

Expression vector	Guanylate cyclase activity*	Specific binding† ^{125}I-labelled α-ANP	^{125}I-labelled pBNP
Control	0.33 ± 0.01	3,240 ± 223	1,087 ± 164
pRK-ANP-BR	3.50 ± 0.01	10,694 ± 1,412	3,643 ± 26
pRK-ANP-AR	1.91 ± 0.01	10,313 ± 893	5,721 ± 1,107

COS-7 cells maintained in Dulbecco's modified Eagles' medium supplemented with 10% FCS were seeded at 5×10^6 cells per 100 mm plate (guanylate cyclase assay) or 1×10^5 per 35 mm plate (binding assay). Twelve hours later, cells were transfected with control vector pRK, the ANP-B receptor expression vector, or the ANP-A receptor expression vector[5] (1 μg ml^{-1}) using DEAE-dextran. The vector pRK-ANP-BR contained nucleotides 253 to 3,470 (Fig. 1) of the ANP-B receptor in the expression vector pRK5 (R. Klein and D.V.G., unpublished results) under the control of the cytomegalovirus immediate early promoter.

* After transfection (48 h) cells were washed with PBS, scraped into 4 ml PBS and homogenized with 40 strokes of a Dounce homogenizer at 0 °C. Nuclei were pelleted and the supernatant was centrifuged at 100,000*g* for 30 min in a SW 55-Ti rotor to obtain a membrane pellet. Membrane proteins were solubilized by incubation on ice for 10 min in solution containing 20 mM HEPES pH 7.4, 100 mM NaCl, 10% glycerol, 1% Triton X-100 and 1 mM DTT. Protein concentrations were measured by a dye-binding assay (BioRad). Guanylate cyclase reactions contained 100 μg membrane proteins in 100 μl 20 mM HEPES, pH 7.4, 30 units of creatine phosphokinase, 1 mM GTP, 4 mM $MnCl_2$ and 0.5 mM isobutyl methylxanthine. After incubation at 37 °C for 10 min, the reaction was stopped by addition of 50 mM acetic acid (500 μl, pH 6.2) and boiled for 3 min. Aliquots were analysed for cGMP after acetylation with 1/20 volume of acetic anhydride/triethylamine (1:2) then radioimmunoassay (Biomedical Technologies). Guanylate cyclase activity is given in pmol cGMP per min per mg protein. Results are expressed as the mean ± 1 s.d. of triplicate determinations.

† After transfection (48 h) cells were washed twice with buffer A (PBS with 0.2% BSA and 0.1% bacitracin) and incubated with 0.5 nM ^{125}I-labelled α-ANP (1,800 Ci mmol^{-1}, Amersham) or ^{125}I-labelled pBNP (600 Ci mmol^{-1}) in 2 ml buffer A at room temperature for 1 h. After the incubation, cells were rinsed with cold PBS, and dissolved in 0.2 M NaOH (2 ml) and radioactivity was measured in gamma counter. All measurements were in triplicate. Background binding was measured by incubating the cells with ^{125}I-labelled α-ANP or ^{125}I-labelled pBNP in the presence of 1 μM α-ANP or pBNP, respectively. Specific binding is given in c.p.m. and was calculated by subtracting the background binding from the total binding.

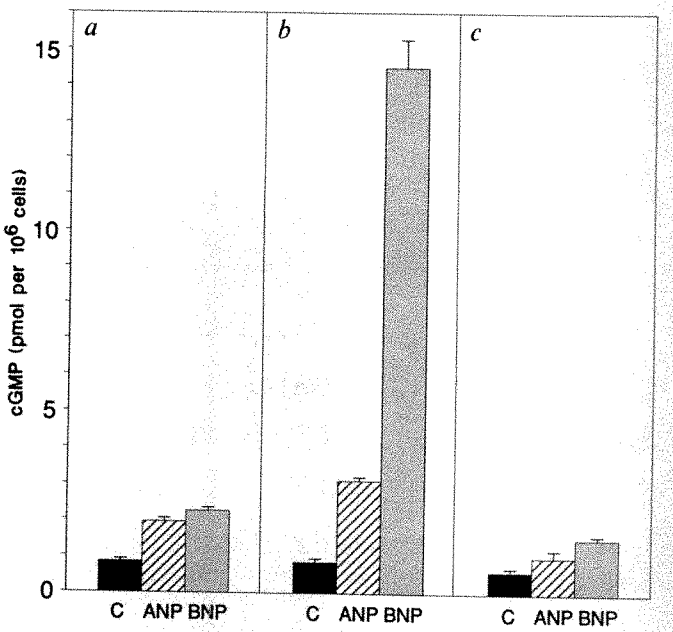

FIG. 3 Stimulation of cGMP production by natriuretic peptide. COS-7 cells transfected with human-ANP-A-receptor expression vector[5] (panel *a*), human-ANP-B-receptor expression vector (panel *b*) or pRK (control; panel *c*), were either not treated (C) or stimulated with 500 nM porcine BNP (BNP) or human α-ANP (ANP) for 5 min. Results are expressed as the mean amount of cGMP (pmol) per culture ± 1 s.d. for 3 independent determinations.
METHODS. COS-7 cells were seeded at a density of 1×10^6 cells per well in a 60 mm plate with high glucose DMEM plus 10% heat-inactivated dialysed calf serum and maintained for 12 h at 37 °C in 7% CO_2, 93% air. Plasmid DNA (3 μg) was transfected with 400 μg ml^{-1} of DEAE-dextran in high glucose DMEM (2 ml) + 10% Nuserum (Gibco) for 4 h. Cells were shocked with 20% glycerol in PBS for 1 min, fresh medium was added and cells were maintained for 72 h before stimulation. Non-treated cultures were incubated at 37 °C in DMEM with 25 mM HEPES pH 7.2, 0.1 mM isobutyl methylxanthine at 37 °C for 10 min, medium was aspirated and 6% trichloroacetic acid was added. Stimulated samples were treated for an additional 5 min in the presence of 500 nM peptide before trichloroacetic acid treatment. Samples were frozen at −20 °C for 1 h, thawed at room temperature, and cell debris was removed by centrifugation at 2,500*g* for 10 min. Samples were extracted once with 4 volumes of water-saturated ether, briefly evaporated and assayed for cGMP as described in Table 1.

messenger cGMP production, together with the apparent specific expression of the ANP-B receptor in some tissues, suggests differential multifactorial control of hypotensive functions. In addition, the expression of BNP and α-ANP may each be subject to different forms of control[18]. The isolation of ANP-B receptor cDNAs exclusively from a human brain cDNA library suggests that this receptor may be the main mediator of natriuretic peptide action in the central nervous system (CNS). BNP is more widely distributed in the rat CNS than α-ANP, with distinct and non-overlapping CNS distribution for these hormones[25]. These observations suggest neuromodulatory functions for BNP beyond the central control of cardiovascular homeostasis[25].

The teleological reasons for different natriuretic peptide/receptor systems in the CNS and some peripheral tissues are not apparent, given the role of cGMP as a second messenger of natriuretic peptide action[1]. According to this hypothesis the differential action of natriuretic peptides in target tissues would be through the expression of different cGMP targets such as a cGMP-gated kidney cation channel[26], a cGMP-regulated phosphodiesterase[27] and the activation of cGMP-dependent protein kinase[28], together with the tissue-specific expression of kinase substrates. As well as expressing different tissue responses to natriuretic peptides, the ANP-B and ANP-A receptors could be subject to different patterns of regulation, or they may each have additional different signal-transduction pathways which are biochemically distinct from cGMP as a second messenger. These possibilities may be reflected in the less conserved (63% identity) kinase homology region, as opposed to the highly conserved (88% identity) cyclase homology region of these two natriuretic-peptide receptors. □

HUMAN T-cell leukaemia virus 1 (HTLV-1) is a retrovirus aetiologically associated with adult T-cell leukaemia (ATL)[1–3], tropical spastic paraparesis (TSP)[4–6] and possibly multiple sclerosis (MS)[7] in humans. Three founder lines of transgenic mice containing the HTLV-1 *tax* gene under the control of the viral long terminal repeat (LTR)[8] have previously been shown to develop neurofibromas[9]. Further analysis of these animals has now revealed that they also develop an exocrinopathy involving the salivary and lachrymal glands. This pathology resembles Sjögren's syndrome, a disease of presumed autoimmune aetiology, features of which are sometimes reported in HTLV-1 associated conditions. Mice with an HTLV-1 *tax* transgene might be a useful model for studying the development of Sjögren-syndrome-like pathology.

Within several weeks after birth of mice containing the HTLV-1 *tax* gene, proliferation of ductal epithelial cells is noted in the submandibular, parotid and minor salivary glands (Fig. 1*b*, *d*). This proliferation is multifocal and occurs diffusely throughout the gland. In the early stages architecture of the acinus remains well preserved and no lymphocytic infiltration is observed, but over the course of several weeks, the ductal proliferation dramatically progresses and the structure is distorted. Ductal proliferation to a lesser degree is also observed in the sublingual gland (Fig. 1*c*), but generally after significant ductal proliferation has occurred in the submandibular and parotid glands. Ductal proliferation also occurs in the accessory salivary glands within the oral cavity of the transgenic mice (Fig. 1*d*).

Lymphocytic infiltration of the salivary glands occurs after there has been significant proliferation of ductal epithelium. Initially, lymphocytes are found adjacent to the proliferating nests of epithelial cells. As the proliferation progresses, lymphocytes as well as plasma cells infiltrate and surround the masses of proliferating cells as well as adjacent slivary gland acini (Fig. 1*e*). Mice surviving six to eight months exhibit extensive epithelial island enlargement with lymphocytic infiltration, leading to destruction of acinus architecture, and hyalinization and thickening of basement membranes (Fig. 1*f*).

Electron-microscopic analysis of the proliferating ductal cells in the salivary gland shows junctional complexes and external lamina without myofilaments consistent with these cells being of an epithelial origin. The nuclei of the proliferating cells exhibit an open nuclear pattern with peripherally clumped chromatin (Fig. 2).

FIG. 2 Electron micrograph of early submandibular ductal proliferation in the 6-2 line. Arrows, nuclei of normal ductal cells; arrowheads, nuclei of abnormal ductal cells. Magnification ×2,400. Tissue preparation as previously described[24].

Nests of proliferating cells are also seen in the lachrymal and harderian glands of these animals, although this tends to occur late and is not as extensive as the proliferation found in the salivary glands.

The degree of salivary-gland pathology in these transgenic mice corresponds to the level of expression of the *tax* gene in the ductal epithelial cells as seen by western blot analysis of tissue extracts. No Tax protein was detected in control-mouse tissues (Fig. 3, lanes 1, 2) but was found in salivary glands of each founder line including lines 6-2, 8-4 and 12-2 (Fig. 3, lanes 3–8). Both male and female adult animals produce equal amounts of Tax protein (Fig. 3, lanes 3–6). Low levels of Tax were measured in 5-week-old mice who exhibited early pathological changes. Tax levels increased progressively three- to fivefold as the mice matured and correlated with the increasing severity of pathological change. Immunocytochemistry performed on tissue sections demonstrated that the Tax protein was localized predominantly in the nucleus (Fig. 1*g*) and particularly in ductal cells during the early stages of the disease (Fig. 1*h*).

The changes occurring in the major and minor salivary glands as well as lachrymal glands resemble features observed in Sjögren's syndrome. Sjögren's syndrome is an exocrinopathy of presumed autoimmune aetiology producing kerato-conjunctivitis sicca (dry eyes) and xerostomia (dry mouth) with a characteristic sialadenitis involving lymphocytic infiltration of the salivary and lachrymal glands[10–12] as well as proliferating nests of epithelial cells. Ultimately, the acinus is destroyed with deposition of hyalin material.

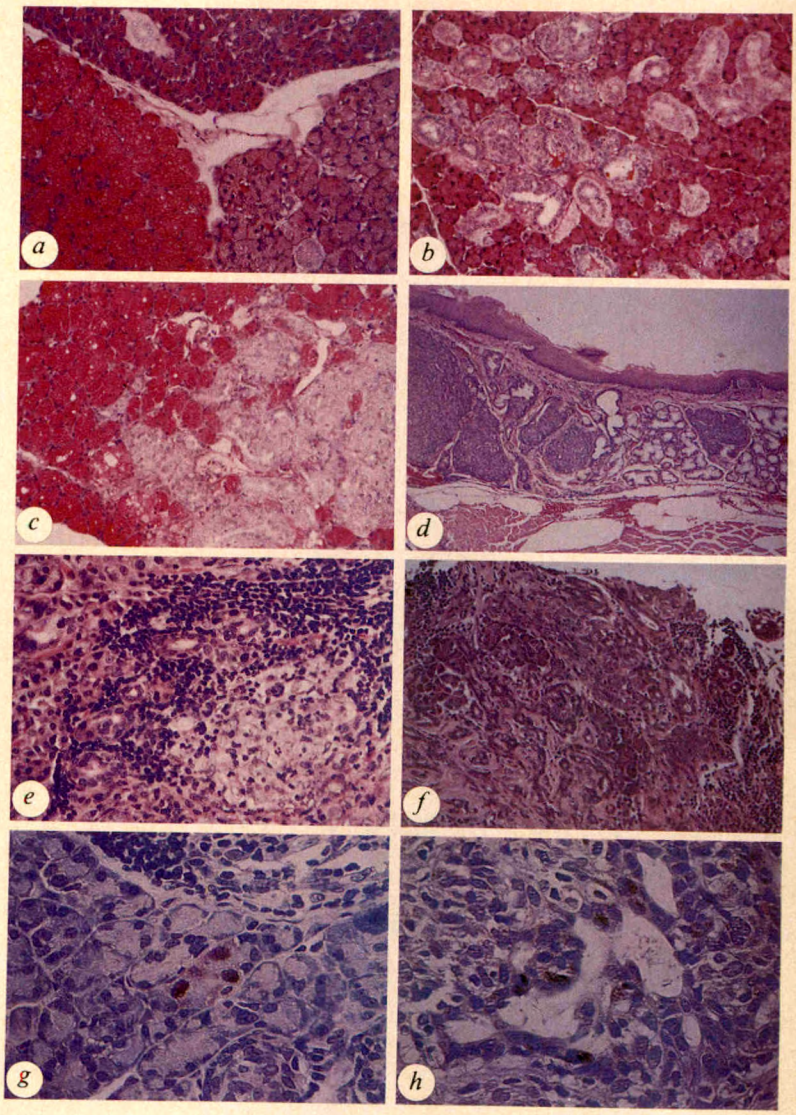

FIG. 1 Microscopic examination of salivary glands from normal (*a*) and HTLV-1-*tax* transgenic mice (*b–h*). Founder series 6-2: *b, c, g, h*; series 12-1: *d–f*. *a*, Normal adult sublingual, submandibular and parotid glands; *b*, submandibular gland, 5 weeks old; *c*, sublingual gland, 11 weeks old; *d*, minor salivary glands of oral cavity, 16 weeks old; *e*, submandibular gland, 20 weeks old; *f*, submandibular gland, 24 weeks old; *g*, submandibular gland, 16 weeks old and *h*, submandibular gland, 16 weeks old. Paraffin-embedded sections of salivary glands, stained by periodic acid-Schiff (*a, b* and *c*) or haematoxylin and eosin (*d, e, f*). Immunocytochemistry using anti-*tax* antibody was performed by standard method[23] (*g* and *h*). Magnifications: ×60(*a–c, f*), ×24(*d*), ×150(*e*), ×240(*g, h*).

Sjögren's syndrome has been associated with a spectrum of lymphoproliferative disorders ranging from benign hyperplasia to overt lymphoma[13]. These transgenic mice also develop marked enlargement of the lymph nodes within and adjacent to the salivary glands. Histologically, this represents significant hyperplasia of the medullary and cortical regions of the lymph nodes as well as plasma cell infiltration. We have not, however, observed the occurrence of a lymphoma in these mice.

An association between HTLV-1 and Sjögren's syndrome has been suggested indirectly through case reports of HTLV-1 infected patients with tropical spastic paraparesis who developed features of Sjögren's syndrome[4,14,15]. Features of Sjögren's syndrome have been reported in intravenous drug abusers[16] who are at high risk of HTLV-1 infection[17].

Although several case reports have described the occurrence of salivary-gland lesions in HIV infected patients[18–20], these studies did not address whether these individuals were also infected with HTLV-1. Epidemiological data suggest that a high proportion of HIV-infected patients are also infected with HTLV-1 (ref. 17).

This transgenic model suggests that HTLV-1 is tropic for ductal epithelium of the salivary and lachrymal glands and produces features which resemble Sjögren's syndrome. The primary event in the development of the exocrinopathy may be a virally induced proliferation and perturbation of the function of ductal epithelium, followed by a lymphocytic response. This sequence of events differs from that proposed by currently accepted models of Sjögren's syndrome pathogenesis, where lymphocytic infiltration is thought to precede ductal cell proliferation[21,22]. Our transgenic model may provide new insights into the study of autoimmune disorders and the pathogenesis of

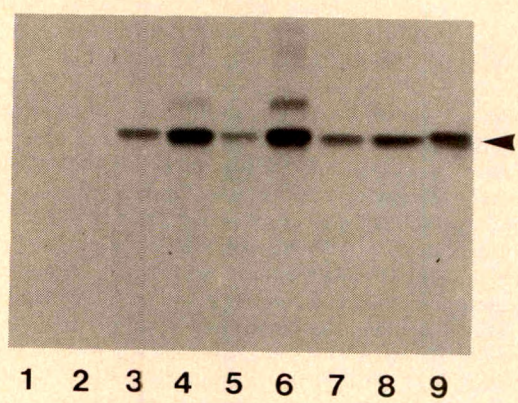

FIG. 3 Protein immunoblot analysis. Lane 1, normal salivary gland; lane 2, normal muscle; lanes 3 and 4, salivary gland and muscle, 6-2-97 male; lanes 5 and 6, salivary gland and muscle, 6-2-98 female; lane 7 and 8, salivary gland and muscle, 12-2-45 male; lane 9, neurofibroma cell line PX-1 derived from a 6-2 mouse. Arrowhead indicates the 40K Tax protein. 80 μg of total protein was loaded per lane and analysed as previously described[8,25]

HTLV-1-induced proliferative diseases induced by the transactivating Tax protein. □

Changing Fos oncoprotein to a Jun-independent DNA-binding protein with GCN4 dimerization specificity by swapping 'leucine zippers'

Joan W. Sellers & Kevin Struhl

Department of Biological Chemistry and Molecular Pharmacology, Harvard Medical School, Massachusetts 02115, USA

A STRUCTURAL motif for DNA-binding proteins, the 'leucine zipper', has been proposed for the *jun*, *fos* and *myc* gene products, the yeast transcriptional activator GCN4, and the C/EBP enhancer-binding protein[1]. These proteins all contain a region with four or five leucine residues spaced exactly seven amino acid residues apart whose sequence is consistent with the formation of an amphipathic α-helix. It has been proposed that the leucine zipper consists of two interdigitated α-helices, one from each monomer, that constitute the dimerization function necessary for high-affinity binding to DNA; an adjacent region of basic residues is thought to be responsible for specific protein–DNA contacts[1]. In support of this model, substitution of the leucine residues within the motif can abolish dimerization and DNA-binding[2–6], and a synthetic peptide corresponding to the GCN4 leucine zipper forms α-helical dimers[7]. Despite the conserved leucine residues, however, each protein has a distinct dimerization specificity. Specifically, GCN4 homodimer, Jun homodimer and Fos–Jun heterodimer proteins bind to the same DNA site, whereas Fos is unable to form homodimers, bind DNA, or interact with GCN4 (refs 8–14). Here, we alter the dimerization specificity of Fos by precisely replacing its leucine zipper with that from GCN4. This Fos-GCN4 chimaeric protein is able to bind to the target site in the absence of Jun, and can form DNA-binding heterodimers with GCN4 but not with Jun. These results indicate that the leucine zipper is sufficient to confer dimerization specificity and strongly suggest that Fos contacts DNA directly.

The products of the nuclear proto-oncogenes *fos* and *jun* form a heterodimeric complex which binds to the transcriptional regulatory element known as the AP-1 site[2,4–6,12–14]. Yeast GCN4 protein binds as a homodimer to target sequences that are indistinguishable from AP-1 sites[8,9]. Extensive analysis indicates that the optimal GCN4 binding site is dyad-symmetric and that each GCN4 monomer directly contacts a half-site[15,16]. By analogy, each subunit of a Fos–Jun heterodimer would be expected to contact a half-site. This idea has been supported by the finding that Fos, Jun, and GCN4 contain a conserved stretch of basic residues equally spaced from their leucine zippers, and mutations in the Fos and Jun basic region prevent DNA-binding, but not dimerization[2,4–6]. Although the failure of Fos to bind DNA could reflect its inability to form homodimers, its contribution to specific DNA-binding could also be by an indirect effect mediated through Jun.

To determine whether the leucine zipper confers dimerization specificity and Fos has the potential to contact DNA, we created Fos^G, a chimaeric protein in which Fos residues 23–160 (including the basic region) are fused to the carboxy-terminal 33 amino acids of GCN4 (containing the leucine zipper, but unable to bind DNA; see ref. 17) (Fig. 1). The spacing of the leucine zipper and the basic domain in Fos^G is identical to that in Fos and GCN4. The LexA domain at the amino-terminus of the protein lacks the dimerization function[18,19] and is irrelevant to these experiments (see below).

To test the DNA-binding properties of Fos^G, ^{35}S-labelled Fos^G was synthesized *in vitro*, incubated with the optimal GCN4/AP-1 site (ATGACTCAT), and electrophoresed in non-denaturing polyacrylamide gels (Fig. 2*a*). A band is seen which is dependent on the addition of both the protein and DNA, indicating that Fos^G can bind to this DNA fragment. We tested the specificity of binding with a DNA containing a point mutation, AGGACTCAT; this mutation leads to a significant reduction in binding by GCN4 and by the Jun–Fos complex[9,10,15]. Complex formation by Fos^G was also greatly reduced by this point mutation, indicating that the chimaeric protein has similar DNA sequence recognition properties to those of GCN4 and the Jun–Fos complex.

The fact that Fos^G binds to the dyad-symmetric GCN4/AP-1 site suggests that it can form homodimers, presumably mediated by the GCN4 leucine zipper. If the leucine zipper confers dimerization specificity, then Fos^G should form heterodimers with GCN4 but not with Jun. Indeed, when we synthesized GCN4 and Fos^G together and incubated them with the target DNA, we observed a new protein–DNA complex with an intermediate mobility (Fig. 2*b*) indicative of heterodimer formation. The Fos^G–GCN4 heterodimer and the GCN4 homodimer bands were of equal intensity, but the presumed Fos^G homodimer band was much fainter. This observation could reflect a decrease in either the dimerization ability or in the affinity for target DNA of the Fos^G homodimer compared with the heterodimer; we favour the latter explanation. In any event, our results exclude the possibility that dimerization by the LexA domain influences binding by Fos^G, because although the heterodimer contains only one LexA moiety, it functions more effectively than the homodimer.

Additional observations indicate that Fos^G is a derivative of Fos with an altered dimerization specificity (Fig. 2*c*). First, when Fos^G and a Jun derivative were co-synthesized, only the Fos^G complex was seen, indicating that Fos^G and Jun cannot form heterodimers. The failure to observe new bands was not due to the co-migration of heterodimer and homodimer complexes, because the relative molecular masses of Fos^G and the Jun derivative differ (under our conditions, the Jun homodimer complex cannot be seen[13]). Second, unlike Fos^G, a Fos derivative does not bind DNA or form a heterodimer complex after co-synthesis with GCN4, but it will form a DNA-binding complex when co-synthesized with Jun (refs 2 and 12–14; data not shown).

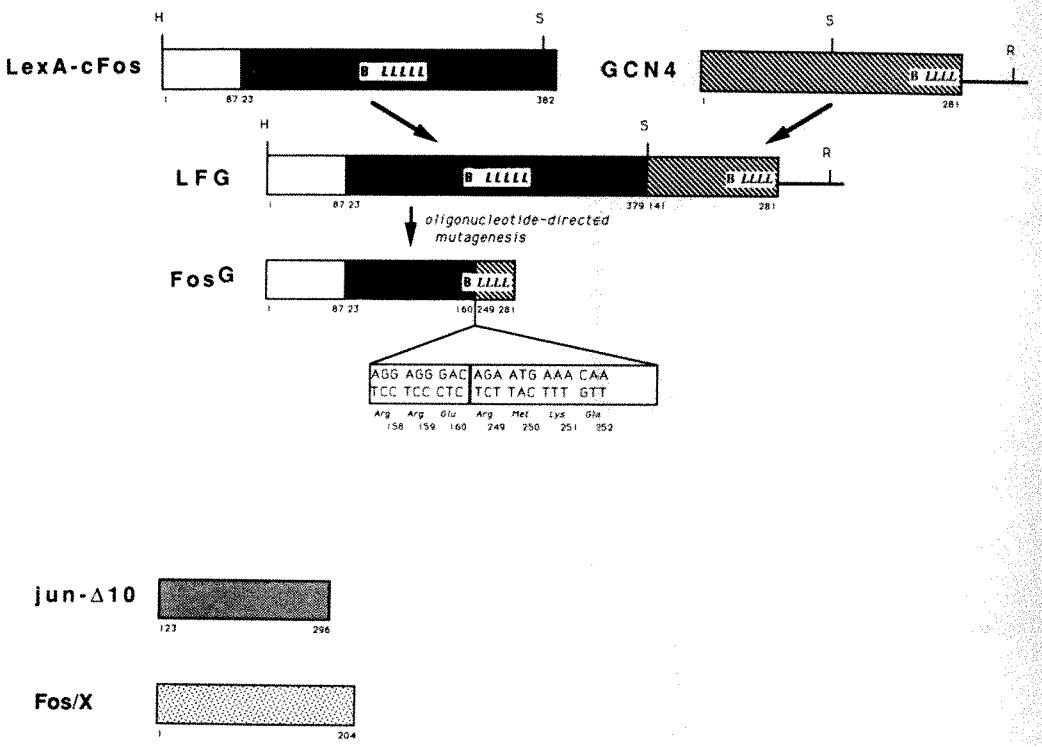

FIG. 1 Structure of proteins. Top line, structure of LexA-c-Fos, which is composed of the LexA DNA-binding domain (open box) fused to the Fos oncoprotein (black box), and the structure of GCN4 (hatched box). Leucine zippers, L; adjacent basic regions, B; H, R and S indicate restriction sites (H, *Hin*dIII site; S, *Sal*I site; R, *Eco*RI site) used in the cloning of LFG, which is shown in the second line from the top. (The wild-type *GCN4* gene does not contain a *Sal*I site; the site shown occurs in *LexA-gcn4-Δ29* (ref. 20), a deleted derivative used in the construction of LFG.) Shown below LFG is Fos^G, with the sequence of the junction between Fos^G and GCN4 indicated. Jun-Δ10 is a deleted Jun derivative. The Fos derivative, Fos/X, was obtained from T. Halazonetis[13]. Numbers below protein structures indicate amino-acid residues. The thick line represents non-coding sequences.

METHODS. The DNA LFG was constructed by joining the *Hin*dIII–*Sal*I fragment of the gene encoding LexA-c-Fos (ref. 21) with the *Sal*I–*Eco*RI fragment of *GCN4* (the *Eco*RI site is downstream of the structural gene) and cloning the resulting fusion into *Hin*dIII/*Eco*RI-digested YCm90, a vector derived from YCp88 (ref. 17) that contain an SP6 promoter and an M13 origin of replication.

The DNA molecule encoding the chimaeric Fos^G protein was generated from LFG by oligonucleotide-directed mutagenesis using uracil-substituted single-stranded templates[22]; the junction between *fos* and *GCN4* was confirmed by sequencing. The *jun* deriative, *jun-Δ10* was generated by cloning the *Sal*I–*Eco*RI fragment of *LexA-jun-Δ5* (ref. 23) into pSP64, a vector containing the SP6 promoter.

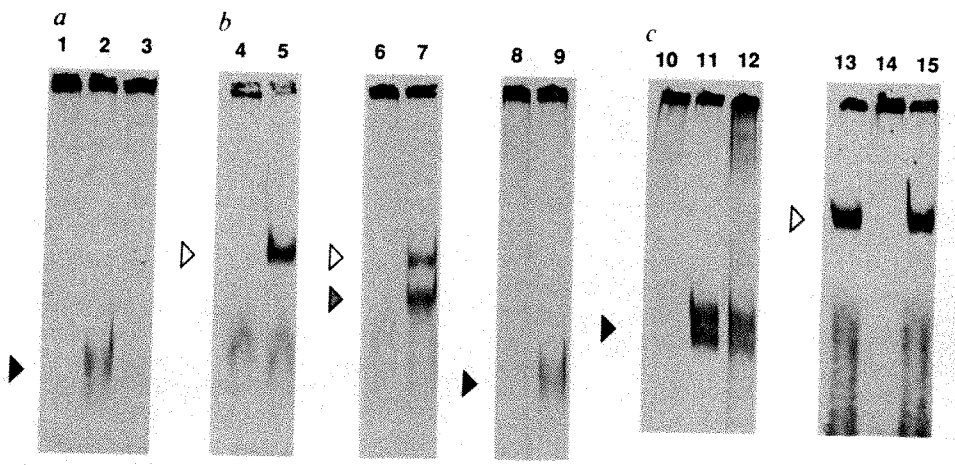

FIG. 2 Specificity of complex formation. *a*, ^{35}S-labelled, *in vitro*-translated Fos^G protein was tested for ability to bind to the GCN4/AP-1 site in the absence of DNA (lane 1), in the presence of a 631-base pair DNA fragment containing the optimal GCN4/AP-1 site ATGACTCAT (lane 2), or in the presence of a similar fragment containing the point mutation AGGACTCAT (lane 3). A DNA–protein complex is observed only in the reaction containing the optimal GCN4/AP-1 site (lane 2, black arrow). *b*, To test for heterodimer formation, GCN4 (lane 5), Fos^G (lane 9) or a co-synthesis of both proteins (lane 7), were each incubated with the 631-base pair fragment containing the optimal GCN4/AP-1 binding site. When synthesized alone, GCN4 (lane 5, open arrow) and Fos^G (lane 9, black arrow) each form complexes. When synthesized together, a new complex of intermediate mobility is seen (lane 7, stippled arrow; see text). In the absence of DNA, no complexes are evident (lanes 4, 6 and 8). The diffuse band at the bottom of lanes 4 and 5 represents a minor artefactual translation product made only in syntheses of full-length GCN4 protein; it is unrelated to any DNA-binding phenomenon because it is found in the absence of added DNA (lane 4; refs 8 and 17). Because this artefactual band is associated only with synthesis of full-length GCN4, it does not interfere with the results, except in lane 7 where it obscures the Fos^G complex band due to almost similar electrophoretic gel mobilities; *c*, To test for specificity of dimerization, Jun (lane 10), Fos^G (lane 11) or a co-synthesis of both Jun and Fos^G proteins (lane 12) were incubated with the optimal binding-site-containing fragment. Only Fos^G complexes are seen (lanes 11 and 12, black arrows). When GCN4 protein (lane 13) or a co-synthesis of GCN4 and c-Fos proteins (lane 15) are incubated with the target DNA, only GCN4 complexes are found. No complex was observed when c-Fos protein alone was incubated with the target DNA (lane 14). The Jun and c-Fos proteins synthesized in these experiments were functional; as expected[12–14], when both proteins are mixed and incubated with the DNA fragment containing the optimal GCN4/AP-1 site, they generate a protein–DNA complex (data not shown). The experiments represented in the separate panels involve different protein preparations, gels and autoradiograph exposure, which accounts for any small differences in the Fos^G complex band intensity between panels.

METHODS. Labelling of protein and analysis of DNA–protein complexes have been described[8,17], except that the binding buffer contained poly(dI · dC) at a final concentration of 100 $\mu g\ ml^{-1}$ instead of salmon sperm DNA. Cellular-Fos protein was generated from pGEM*Fos X* (from T. Halazonetis). Yields and purity of protein preparations were routinely established by SDS-PAGE and autoradiography.

An important conclusion from our results is that the leucine zipper is sufficient to confer dimerization specificity. Specifically, Fos^G contains only the 33 C-terminal residues of GCN4 (the leucine zipper region) but, unlike Fos, can form heterodimers with GCN4 but not with Jun. Moreover, these observations together with the fact that Fos^G alone binds the GCN4/AP-1 site strongly suggest that the leucine zipper is sufficient for dimerization *per se*. (The possibility that other regions of Fos and GCN4 contribute a common, non-specific dimerization function cannot be excluded, but seems unlikely.) These results agree with an earlier observation that a synthetic peptide containing the 33 C-terminal residues of GCN4 forms stable dimers[7]: the conditions here were more physiological, however (concentrations 10^4–10^5 times lower) and experiments were performed in the context of an intact DNA-binding domain.

The leucine-zipper motif was initially defined by the presence of four to five leucine residues spaced seven amino-acid residues apart in a region of the protein that could permit the formation of an α-helix; other than this, there was little overall amino-acid sequence similarity[1]. The fact that swapping the leucine zipper of Fos for that of GCN4 yields a specific DNA-binding protein indicates that these regons are functionally homologous. Nevertheless, it is clear that although the conserved leucines are important for the dimerization of C/EBP (ref. 3), Fos[2,4–6], Jun[4,5], and GCN4 (J.W.S., W. J. van Heeckeren and K.S., unpublished results), other non-conserved residues in the various zipper regions must be involved in dimerization specifiicity. Thus, the ability of this class of proteins to form homodimers or heterodimers will depend on the association properties of individual leucine-zipper regions.

Another conclusion from our experiments is that Fos has an inherent specific DNA-binding activity. Because the GCN4 leucine-zipper region alone does not bind DNA[17], some region of Fos (probably the basic region) must contribute to the ability of Fos^G to interact directly with specific DNA sequences. Furthermore, because the GCN4 leucine zipper can convert Fos into a DNA-binding protein that bypasses the requirement for Jun, the failure of native Fos to bind to DNA almost certainly reflects its inability to form homodimers. In terms of the Fos–Jun heterodimer, these considerations strongly argue against the model that Fos indirectly affects DNA-binding by Jun. Instead, they indicate that Fos and Jun monomers in the heteromeric complex interact with adjacent half-sites.

Finally, chimaeric proteins such as Fos^G should be useful in elucidating the function *in vivo* of proteins involved in heteromeric complexes. For example, transcription involving the AP-1 site is regulated by phorbol esters[10,11], a process which might be mediated by Jun and/or Fos. As Fos^G derivatives can bind to the AP-1 site without Jun, it should be possible to separate the effects of these two oncoproteins. Chimaeric proteins containing the GCN4 leucine zipper could be used to investigate how proteins with leucine zippers might bind DNA specifically. For example, specific DNA-binding by the Myc oncoprotein has yet to be demonstrated, but perhaps by replacing its leucine zipper with that from GCN4, Myc could be converted to a DNA-binding protein whose target sites might be identified by the random selection method[16]. □

Alternative production of calcitonin and CGRP mRNA is regulated at the calcitonin-specific splice acceptor

Ronald B. Emeson*, Farah Hedjran*, Joanne M. Yeakley*†, Jeffrey W. Guise* & Michael G. Rosenfeld*§

§ Howard Hughes Medical Institute, * Eukaryotic Regulatory Biology Program, † Department of Biology, School of Medicine, University of California, San Diego, La Jolla, California 92093, USA

ALTERNATIVE splicing of eukaryotic messenger RNA precursors represents a common mechanism for generating multiple transcripts from a single gene[1,2]. Although there has been increasing information concerning the sequence requirements and the biochemical mechanisms involved in the constitutive splicing of primary RNA transcripts, very little is known about the sequences or mechanisms which determine alternative RNA-processing events in complex transcription units[3–6]. The calcitonin/calcitonin gene-related peptide (CGRP) primary RNA transcript undergoes tissue-specific alternative processing, resulting in the differential production of calcitonin mRNA in thyroid C cells and CGRP mRNA in neurons of the central and peripheral nervous systems[7,8]. To elucidate the molecular mechanisms underlying these alternative RNA processing events, we have examined the nucleotide sequences involved in the production of calcitonin and CGRP mRNAs. Analyses of HeLa and F9 cell lines transfected with a variety of mutant calcitonin/CGRP transcription units have demonstrated that alternative splice-site selection is primarily regulated by *cis*-active element(s) near the calcitonin-specific 3′-splice junction. We suggest that the tissue-specific pattern of alternative RNA processing is conferred by sequence information at the calcitonin-specific acceptor which serves to inhibit the production of calcitonin transcripts in CGRP-producing cells.

The rat calcitonin/CGRP gene is comprised of six exons; calcitonin mRNA is produced by splicing of the first three exons to the fourth exon, accompanied by cleavage and polyadenylation at the 3′ end of the fourth exon. CGRP mRNA production results from the splicing of the first three exons to the fifth and sixth exons and use of a distal poly(A) site at the 3′ end of the sixth exon (Fig. 1*a*)[7,9]. Previous studies on the expression of a metallothionein-calcitonin/CGRP fusion gene in transgenic mice demonstrated that almost all tissues produced predominantly calcitonin mRNA[10]. In most neurons however, CGRP transcripts represented the main RNA species. The simplest interpretation of these results is that the ability to splice the calcitonin/CGRP primary transcript to produce mature CGRP mRNA requires a neuron-specific splicing machinery, thereby suggesting that calcitonin mRNA is likely to represent the unregulated splicing choice. Alternatively, production of calcitonin-specific transcripts could require a tissue-specific factor which is widely distributed, but absent from neuronal tissues.

Two potential mechanisms have been proposed for the regulation of alternative splice-site use in the calcitonin/CGRP gene. One mechanism involves sequence or site-specific poly(A) site

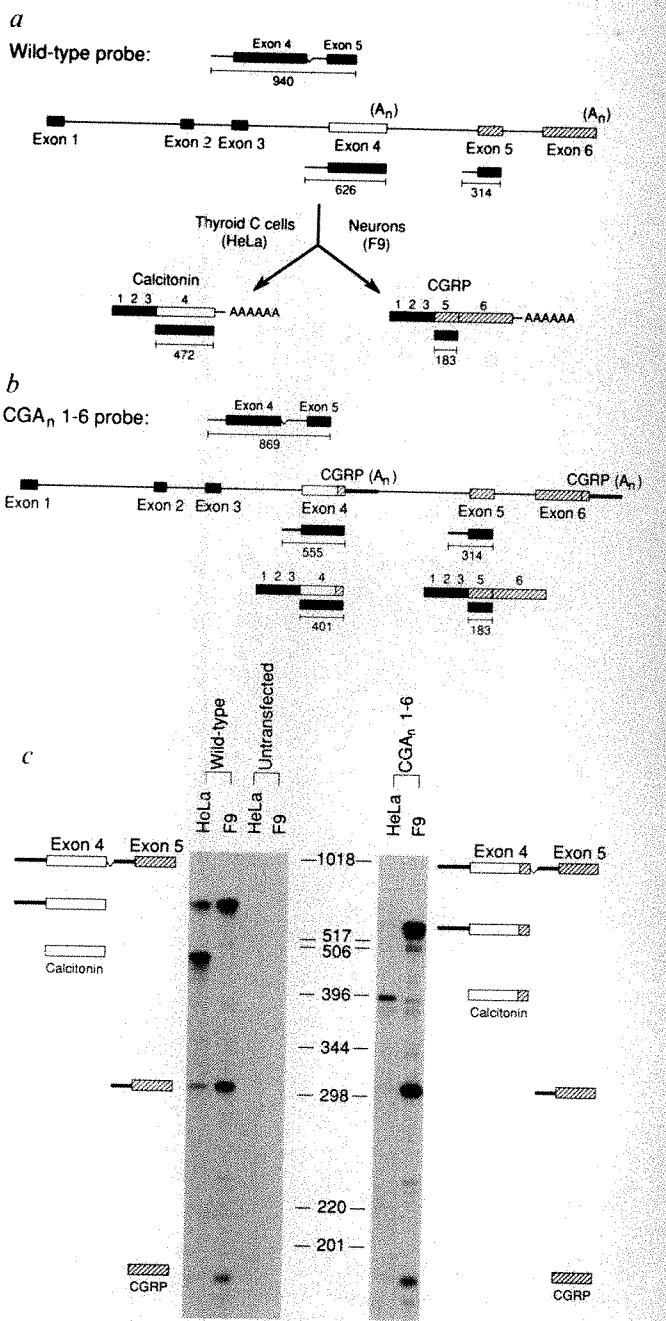

FIG. 1 Replacement of the calcitonin poly(A) site does not alter differential processing of the calcitonin/CGRP transcript. *a*, Schematic representation of the rat calcitonin/CGRP primary transcript demonstrating differential RNA processing in neurons and thyroid C cells. A wild-type RNA probe for ribonuclease protection analysis containing adjacent intron/exon sequences at the calcitonin (exon 4) and CGRP-specific (exon 5) splice junctions is shown; structures and sizes of predicted RNase protection fragments are indicated. *b*, A mutant transcription unit (CGA_n 1–6) in which the calcitonin poly(A) site (−140 to +54 relative to the 3′ end of the fourth exon) was replaced with a fragment containing the CGRP poly(A) site (−69 to +256 relative to the 3′ end of the sixth exon) is shown; the structures and sizes of predicted RNAse protection fragments are schematically indicated. *c*, RNAse protection analyses of RNA from untransfected and HeLa or F9 permanent transfectants expressing either the wild-type or CGA_n 1–6 calcitonin/CGRP transcription units are shown; structures and migration positions of predicted RNase protection fragments and radiolabelled DNA markers (1 kb ladder; BRL) are indicated.

METHODS. Permanently transfected cell lines were established using calcium phosphate co-precipitation with plasmids containing the neomycin resistance gene and the calcitonin/CGRP transcription unit as previously described[11,25]. Polyclonal populations of G418-resistant clones were selected and RNA was prepared by the guanidinium-isothiocyanate method[26]. For construction of the wild-type RNase protection probe, a 154-bp region from the 3′ end of the third intron and the complete calcitonin-specific exon (exon 4) was fused to sequences corresponding to 131 bp from the 3′ end of the fourth intron and the complete CGRP-specific exon (exon 5). Construction of an RNase protection probe specific for the CGA_n 1–6 transcription unit was made in a parallel manner. DNA fragments were obtained by amplification of specific genomic sequences from the wild-type and mutant transcription units using the polymerase chain reaction (PCR) with *Taq* DNA polymerase (Perkin-Elmer/Cetus) and synthetic oligonucleotides according to manufacturer's instructions. Amplified DNA fragments were then cloned into a transcription vector (pBKS II; Stratgagene), linearized with *Hind*III and anti-sense RNA was transcribed (specific activity = 4×10^8 c.p.m. μg^{-1}) using T7 RNA polymerase in the presence of [α-^{32}P]UTP. Ribonuclease protection assays were performed essentially as described[27]; total cellular RNA (1–10 μg) was hybridized to 5×10^5 c.p.m. of a labelled antisense RNA probe at 45 °C for 14–18 h. Ribonuclease A digestion (20 $\mu g\ ml^{-1}$) was carried out at 30 °C for 45 min. Protected RNA fragments were separated by size on a 4% acrylamide/7 M urea gel as previously described[27]. Densitometric analyses of RNase protection autoradiograms were performed using an LKB Ultroscan XL densitometer. Quantitation of the relative levels of specific RNA species was calculated by correcting integrated densitometric peak areas for the number of uridine residues present in each protected fragment.

selection, and another proposes that choice of the 3′ (acceptor) splice-site is the critically regulated event. In order to investigate such mechanisms, we have developed model systems in which transfected cell lines exhibit mRNA-processing choices analogous to those observed *in vivo*[11]. A ribonuclease protection assay was used to quantitate accurately alternative splice-site use in such cell lines (Fig. 1*a*). Human epithelial (HeLa) and mouse teratocarcinoma (F9) cell lines, permanently transfected with the wild-type rat calcitonin/CGRP gene, paralleled the alternative RNA processing events demonstrated by thyroid C cells (>98% calcitonin mRNA) and neurons (>94% CGRP mRNA), respectively (Fig. 1*a*, *c*). Both cell lines also generated protected fragments corresponding to RNA species in which cell-specific RNA processing had not occurred. Hybridization analyses to size-fractionated RNA (data not shown) confirmed the cell-specific alternative RNA processing events and demonstrated the accumulation of significant levels of high molecular weight RNA species previously identified as partially processed nuclear RNA precursors[11,12].

Although *in vitro* splicing analyses of calcitonin/CGRP transcripts have suggested that alternative RNA processing may be regulated by cell-specific poly(A) site selection[13], calcitonin- and CGRP-producing cell lines exhibited no differential poly(A) site utilization when transfected with transcription units in which the calcitonin and CGRP poly(A) sites were placed in tandem array[11]. To further address this question, a calcitonin/CGRP transcription unit was constructed in which the calcitonin (exon 4) poly(A) site was replaced by sequences containing the CGRP (exon 6) cleavage/polyadenylation signal (Fig. 1*b*). Analyses of mRNA from cell lines transfected with the mutant (CGA_n 1–6) calcitonin/CGRP transcription unit revealed cell-specific splice acceptor use similar to that of the wild-type gene for both cell types (Fig. 1*c*). Replacement of the calcitonin poly(A) site with sequences containing the CGRP cleavage/polyadenylational signal neither increased utilization of the calcitonin-specific splice acceptor in F9 cells (94% CGRP), nor altered calcitonin acceptor use in transfected HeLa cells (99% calcitonin). These experiments strongly suggest that differential

poly(A) site utilization is not the key regulatory event involved in calcitonin/CGRP alternative RNA processing, indicating that tissue-specific processing of this gene is regulated by alternative splice-site selection.

The observation that alternative splicing occurs in a tissue-specific manner has suggested that *trans*-acting factors must interact with the pre-mRNA; however, *cis*-active elements within the transcript must ultimately determine the nature of the final

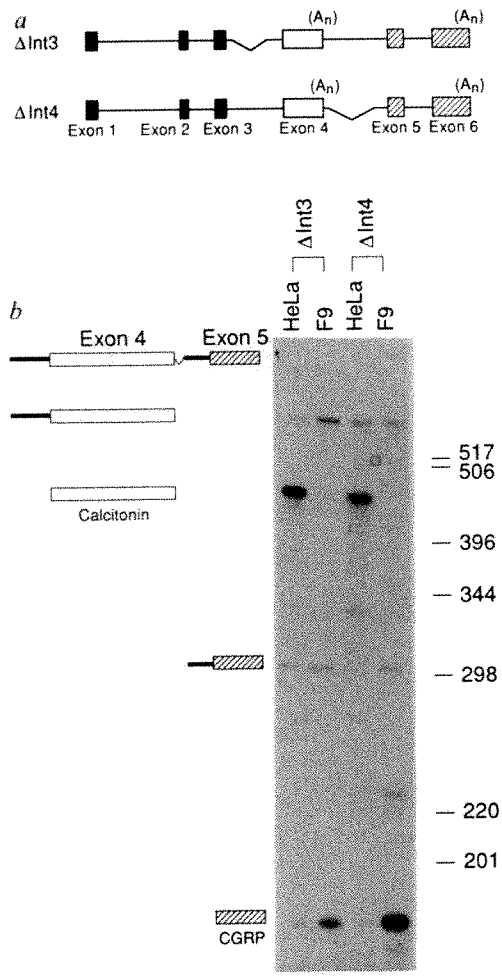

FIG. 2 Large deletions in the third and fourth introns do not affect calcitonin/CGRP alternative processing. *a*, Schematic representations of mutant calcitonin/CGRP transcription units indicating the locations of a 380-bp deletion in the third intron (ΔInt3) and a 590-bp deletion in the fourth intron (ΔInt4). *b*, Ribonuclease protection analyses of RNA from polyclonal permanent transfectants expressing the ΔInt3 and ΔInt4 calcitonin/CGRP transcription units demonstrates maintenance of cell-specific differential RNA processing; the structures and migration positions of predicted RNase protection fragments are indicated. The migration position of radiolabelled DNA markers are designated.

METHODS. Construction of the ΔInt3 transcription unit involved cleavage of the wild-type calcitonin/CGRP gene at a unique *Bst*E II site, 77 bp downstream from the exon 3 splice donor, followed by subsequent digestion with *Bal* 31 exonuclease as previously described[27]. The extent of the deletion, from the *Bst*E II site to a point 206 bp upstream from the fourth exon, was determined by DNA sequence analysis of double-stranded DNA templates according to the chain-termination method of Sanger *et al.*, using synthetic oligonucleotide primers and T7 DNA polymerase (Sequenase; United States Biochemicals)[27]. Construction of the ΔInt4 transcription unit was made by introduction of an *Eco*RI restriction site into the fourth intron 119 bp upstream from the CGRP-specific splice acceptor site by oligonucleotide-directed mutagenesis in M13mp18 as previously described[28]; the deletion extended from a *Bgl*II site, 55 bp downstream from the 3′ end of the fourth exon, to the introduced *Eco*RI restriction site. Ribonuclease protection assays, using the wild-type RNase probe, and densitometric analyses were performed as described in Fig. 1.

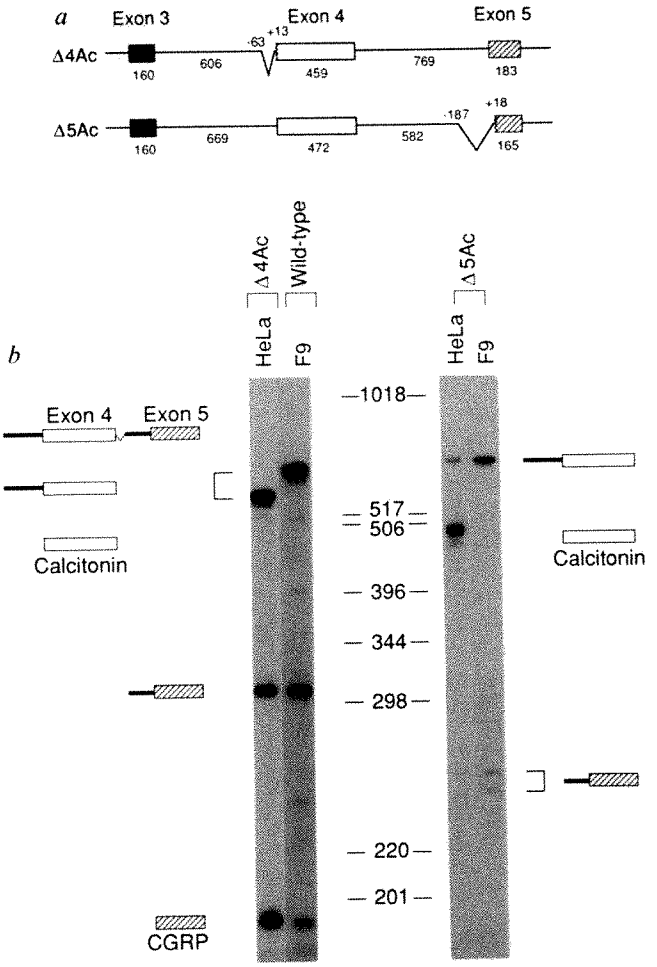

FIG. 3 Exon 4 and exon 5 splice acceptor deletions reveal that regulation of calcitonin/CGRP alternative RNA processing is at the calcitonin-specific splice acceptor. *a*, Schematic diagrams of a portion of mutant calcitonin/CGRP transcription units in which either the calcitonin- (Δ4Ac) or CGRP-specific (Δ5Ac) splice acceptor regions have been deleted. The coordinates of the deletions, relative to the beginning of either the fourth or fifth exons, and the sizes of adjacent exons and introns are indicated. *b*, Ribonuclease protection analyses of RNA from permanently transfected HeLa and F9 polyclonal cell lines expressing the wild-type, Δ4Ac or Δ5Ac calcitonin/CGRP transcription units; the structures and migration positions of predicted RNase protection fragments and radiolabelled DNA markers are indicated. A doublet representing an RNA species in which CGRP-specific splicing has not occurred (bracketed) is presumed to result from transient denaturation of an A+T-rich region during the assay.

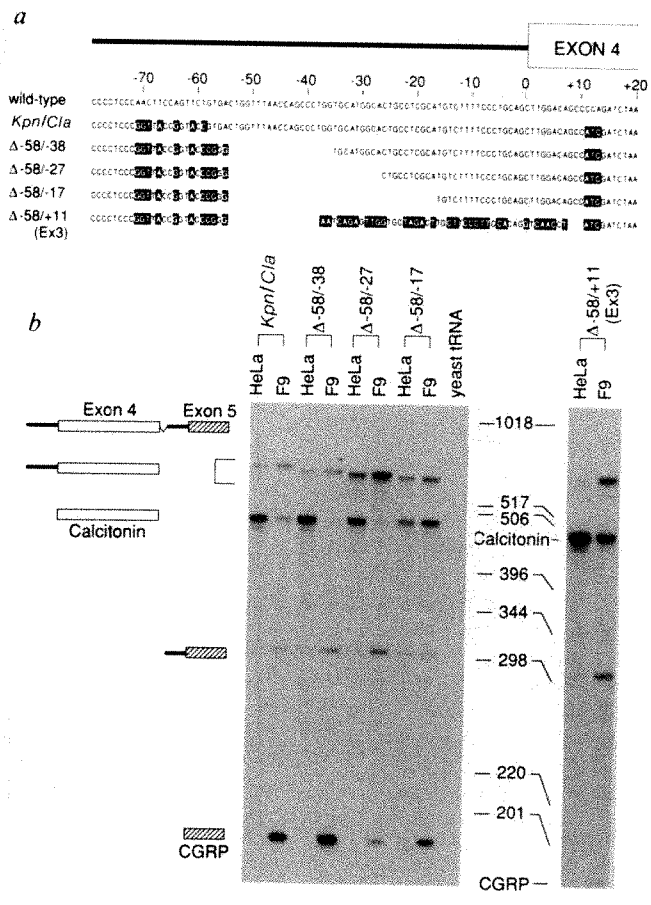

METHODS. Construction of the Δ4Ac calcitonin/CGRP transcription unit was made by introduction of a unique *Kpn*I restriction site, 63 bp upstream of the fourth exon, and a *Cla*I restriction site, 13 bp into the fourth exon, by oligonucleotide-directed mutagenesis in M13mp18, as previously described[28]; deletion of the calcitonin-specific splice acceptor region involved removal of the 77bp *Kpn* I–*Cla* I fragment. Construction of the Δ5Ac transcription unit was made by introduction of a *Sma*I restriction site, 187 bp upstream from the fifth exon, and an *Bam*HI site, 18 bp into the fifth exon, by utilization of the polymerase chain reaction (PCR) with synthetic oligonucleotides. The transcription unit was reassembled using standard techniques, deleting the sequence between the introduced sites. Construction of RNase probes specific for the Δ4Ac and Δ5Ac transcription units has been described in Fig. 1. A 550-bp fragment of the Δ4Ac transcription unit extending from a position 91 bp upstream from the fourth exon to the end of the calcitonin-specific exon was fused to sequences corresponding to 131 bp from the 3′ end of the fourth intron and the complete CGRP-specific exon (exon 5). An RNase probe specific for the Δ5Ac transcription unit was constructed containing a 154-bp region from the 3′ end of the third intron and the entire calcitonin-specific exon (exon 4) fused to a 251-bp DNA fragment containing 165 bp of exon 5 sequence information and 85 bp of adjacent intervening sequence information from the fourth intron.

spliced products. To examine putative *cis*-active elements involved in alternative splice-site selection, initial attention focused on intervening sequence information between the third and fifth exons. Intron deletions were designed to conserve *cis*-active sequences necessary for constitutive splicing, including the 5'-donor, lariat branchpoint, 3'-acceptor and polyadenylation signal[3,5,14,15]. A 380-base-pair (bp) fragment beginning 77 bp downstream from the exon-3 splice donor site was deleted from the third intron of the calcitonin/CGRP gene (Fig. 2*a*). Ribonuclease protection analyses of HeLa cells expressing this transcription unit (ΔInt3) revealed that calcitonin mRNA continued to be the predominant product, representing 98% of the mature RNA species, whereas F9 cells still produced >97% CGRP transcripts (Fig. 2*b*). Analyses of a 590-bp deletion in the fourth intron beginning 55 bp downstream from the end of the fourth exon (ΔInt4; Fig. 2*a*) revealed that deletion of most of the fourth intron also had little effect on alternative RNA processing in these cells lines (Fig. 2*b*). These results demonstrated that most of the RNA sequence information within the third or fourth introns was not essential for alternative splice-site selection.

CGRP mRNA production could reflect the actions of either a positive *trans*-acting factor(s) that promotes use of the CGRP-specific splice acceptor or a negative factor that inhibits the use of the calcitonin-specific splice acceptor. Previous studies have suggested that removal of a 369-bp fragment from the 3' end of the third intron results in the production of significant levels of CGRP mRNA in a calcitonin-producing cell line[11]. To examine the role of sequence information at the calcitonin-specific acceptor itself, a 77-bp fragment containing the exon 4 3'-splice junction was deleted from the calcitonin/CGRP transcription unit (Δ4Ac; Fig. 3*a*). The 5' end of this deletion was chosen to minimize any cryptic splice acceptor selection by removing a potential branchpoint sequence located 55 nucleotides upstream from the 5' end of the fourth exon[16]. Transfection of this transcription unit into HeLa cells resulted in the production of mature CGRP mRNA, yielding an RNA-processing pattern virtually identical to F9 cells transfected with the wild-type gene (Fig. 4*b*). Because calcitonin-producing cells could use the CGRP-specific splice acceptor, there appeared to be no mandatory requirement for a positive cell-specific *trans*-acting factor(s) to promote exon 3 to exon 5 splicing for generation of mature CGRP mRNA.

To investigate the potential role of an inhibitory factor acting at the calcitonin-specific 3'-splice junction, the ability of CGRP-producing cells to alter their splice-site selection in favour of calcitonin mRNA production was investigated by removal of the CGRP-specific splice acceptor site (Δ5Ac; Fig. 3*a*). The 5' end of this 206-bp deletion removed a potential branchpoint sequence, just upstream of a 150-nucleotide polypyrimidine stretch before the CGRP-specific splice acceptor site, and continued 18 nucleotides into the fifth exon[17]. Transfection of this mutant transcription unit into HeLa cells resulted in the normal production of mature calcitonin mRNA; however, F9 cells produced only unprocessed RNA species (Fig. 3*b*). These results suggested that, in the absence of a functional CGRP-specific splice acceptor, CGRP-producing cells were incapable of altering their differential splice-site selection to produce calcitonin mRNA, consistent with a cell-specific inhibition of the calcitonin splice acceptor site.

To further examine *cis*-active elements near the calcitonin-specific splice acceptor site, a series of calcitonin/CGRP transcription units were constructed containing nested deletions

c

Construct	Percentage alternative splice site usage			
	HeLa		F9	
	Calcitonin	CGRP	Calcitonin	CGRP
wild-type	>99	—	6	94
KpnI/Cla	>99	—	7	93
Δ-58/-38	>99	—	2	98
Δ-58/-27	>99	—	16	84
Δ-58/-17	92	8	28	72
Δ-58/+11 (Ex3)	>99	—	82	18

FIG. 4 Deletion or replacement of sequence information at the calcitonin-specific splice acceptor alters the RNA-processing choice of F9 cells. *a*, Nucleotide sequences of wild-type and mutant calcitonin-specific splice acceptors. Alterations from the wild-type sequence are indicated by the boxed letters. *b*, Ribonuclease protection analyses of RNA from permanently transfected HeLa and F9 polyclonal cell lines expressing calcitonin/CGRP transcription units containing mutations of the calcitonin-specific splice acceptor region. A progressive decrease in the size of the protected RNA fragment corresponding to an RNA species in which splicing to the calcitonin-specific acceptor has not occurred (bracketed), results from the progressively larger deletions. The structures and migration positions of predicted RNAse protection fragments and radiolabelled DNA markers are indicated; yeast transfer RNA (20 μg) was included as a negative control. *c*, Densitometric quantitation of the relative levels of calcitonin- and CGRP-specific splice acceptor use in permanently transfected HeLa and F9 polyclonal cell lines. METHODS. Mutations of the calcitonin-specific splice acceptor were made by introduction of unique *Kpn I* (GGTACC) and *Cla* I (ATCGAT) restriction sites as indicated in panel *a* by oligonucleotide-directed mutagenesis in M13mp18 (ref. 28). Mutations were generated by insertion of double-stranded synthetic oligonucleotides into the introduced sites in the calcitonin/CGRP transcription unit; an internal *Sma* I restriction site (CCCGGG) was included in each insert for diagnostic purposes. Ribonuclease protection and densitometric analyses were performed as described in Fig. 1. RNAse protection probes specific for each transcription unit were generated as described in Fig. 1. Each probe contains sequences from the 3' end of the third intron, from a common endpoint 154 bp upstream from the fourth exon in the wild-type gene, to the end of the calcitonin-specific exon (exon 4) fused to sequences corresponding to 131 bp from the 3' end of the fourth intron and the complete CGRP-specific exon (exon 5).

from a common 5′-endpoint 58 nucleotides upstream from the fourth exon (Fig. 4*a*). Introduction of *Kpn*I and *Cla*I restriction sites alone, allowing construction of these nested deletions, had little effect on cell-specific alternative splice-site selection (Fig. 4*b*, *c*). Deletion of a region between −58 and −38 (Δ−58/−38) had no apparent effect on alternative splicing. Further deletion from −58 to −27 (Δ−58/−27) resulted in continued use of the calcitonin acceptor in HeLa cells with increased levels of unprocessed RNA precursors. F9 cells transfected with this mutant transcription unit produced increased levels of unprocessed RNA species and an apparent increase in the ratio of calcitonin to CGRP mRNA. Additional deletion from −58 to −17 (Δ−58/−17) further increased the percentage of calcitonin-specific splice acceptor use in the CGRP-producing cell line. Sequence analysis of RNA from this transcription unit confirmed that accurate splicing of the exon 3 donor to the exon 4 acceptor had occurred in both cell types (data not shown). These results suggested that a *cis*-active element near the calcitonin acceptor inhibited the formation of calcitonin transcripts in F9 cells and that deletion of this element(s) permitted the increased production of calcitonin mRNA in the CGRP-producing cell line.

Further nested deletions near the calcitonin-specific acceptor were not feasible owing to the presence of the splice acceptor consensus sequence, $(Py)_{10}GCAG$, which has previously been shown to be critical for constitutive splicing[18]. In order to further define *cis*-active elements at the calcitonin acceptor itself, the entire splice acceptor region, corresponding to the coordinates −58 to +11 was removed and replaced with a heterologous splice acceptor that could be used by both cell types (Δ−58/+11 (Ex3); Fig. 4*a*). We chose a region of the exon 3 splice acceptor from −39 to +8 relative to the beginning of the third exon. When transfected into HeLa cells, this transcription unit resulted in the production of calcitonin transcripts only, whereas F9 cells now produced ~82% calcitonin mRNA (Fig. 4*b*, *c*). Sequence analysis of RNA from F9 cells transfected with this transcription unit confirmed the accuracy of splicing (data not shown). These results demonstrated that removal of sequence information from the calcitonin-specific 3′-splice junction and its replacement with an acceptor that could be used by F9 cells resulted in the efficient production of mature calcitonin mRNA in a CGRP-producing cell line.

We have demonstrated that tissue-specific processing of the calcitonin/CGRP primary transcript is the result of alternative splice-site selection primarily regulated by *cis*-active sequences at the calcitonin-specific 3′-splice junction. Deletion of sequence information at the calcitonin acceptor results in an alteration of splice-site selection in CGRP, rather than calcitonin-producing cells. These results are most consistent with a model in which *cis*-active sequences serve to inhibit the formation of calcitonin mRNA in the CGRP-producing cell line. Recent genetic analyses of developmental loci in *Drosophila melanogaster* have suggested that specific gene products, with putative RNA-binding domains, may regulate alternative splicing in the sex-determination pathway[19–21]. Such *trans*-acting factors may affect differential RNA processing by binding to specific *cis*-active pre-mRNA sequences, thereby promoting or repressing the selection of alternative splice sites[22–24]. Further definition of the *cis*-active element(s) involved in the production of calcitonin and CGRP messenger RNA may help to isolate and characterize the cell-specific *trans*-acting factor(s) involved in the tissue-specific RNA processing of this gene. □

CORRECTION

Spatial and temporal expression of the retinoic acid receptor in the regenerating amphibian limb

Vincent Giguère, Estelita S. Ong, Ronald M. Evans & Clifford J. Tabin

Nature **337**, 566–569 (1989).

As part of the above report of the temporal and spatial expression of a retinoic acid receptor (RAR) during amphibian limb regeneration, we isolated cDNA sequences from a regenerating newt cDNA library using a human RARα probe (in humans two distinct RARs were known, called RARα and RARβ). As described, two non-overlapping cDNAs were interpreted as representing contiguous portions of a single newt gene product. A chimaera constructed by fusing the two clones at a common *Eco*RI site was shown to function as a retinoic acid receptor in an *in vitro* assay.

Recent work by C. Ragsdale, P. B. Gates and J. P. Brockes has resulted in the isolation of a newt RAR cDNA referred to as RARδ whose 3′ sequence is identical to clone NB6 in our report but whose 5′ sequence differs from one clone NB8. This suggests that the two cDNAs we isolated originated as transcripts from two distinct, although closely related genes. With 5′ sequence information provided by J. Brockes and colleagues, we have used the polymerase chain reaction (PCR) to examine both genomic DNA and newt mRNA. The results verify the existence of two distinct genes and gene products. Moreover, RNAse protection experiments using a probe spanning our chimaeric junction confirm that the two sequences we fused are not found on a contiguous RNA transcript. Accordingly, our published sequence should be interpreted as representing the partial sequence of two different genes: RARβ (the clone NB8 in our paper) and a novel β-like RAR (clone NB6).

Since the probe used for our *in situ* hybridizations was derived solely from the clone NB8 the revised sequence interpretation does not affect the data or the conclusions presented in our paper. In addition, our work together with the results from the Brockes laboratory leads to the intriguing conclusion that there are at least two β-like RARs expressed in the regenerating limb. □

Environmental SEM premières

N. Baumgarten

The environmental scanning electron microscope (SEM) eliminates the high-vacuum requirement of conventional SEM, allowing the analysis of unprepared, wet samples.

DURING the past three decades, the scanning electron microscope (SEM) has opened a window into the fascinating, often beautiful, 3-dimensional microcosm beyond the reach of glass optics. In principle, the SEM works like a television cathode-ray tube, with an electron gun, deflection coils and focusing lenses. Its beam path, or column, must be kept scrupulously clean and evacuated to pressures near those found on the surface of the moon. A fine flow of electrons, focused to a point less than one micron in diameter, is scanned over the specimen surface in a raster pattern, while the 'reflected' electron signal modulates the brightness of a synchronously scanned display screen. Image magnifications from 10× to 100,000× and beyond may be obtained by varying the size of the projected raster.

From the beginning, however, there have been large classes of objects whose physical properties kept them 'off-limits' to electron beam inspection by making them incompatible with the SEM's high-vacuum environment. The near-impossibility of viewing wet, oily or electrically insulating specimens in their natural states has given rise to the routine use of preparation techniques such as drying, freezing, fracturing and conductive coating[1]. But even with specimens that can be prepared to be tolerated by the SEM's vacuum system, there is no simple way to determine whether the structures of interest have been altered or masked by the preparation process[2]. Certain kinds of materials, especially in biological fields, have until now effectively resisted all attempts at direct SEM imaging.

Although sporadic attempts have been made over the years to render the SEM accessible to real-world specimens[3,4], none has ever gained wide acceptance because of the various complications and sacrifices in performance required. Only recently has an instrument been developed that can make high-resolution secondary-electron images of virtually any specimen, regardless of composition. The environmental SEM (or E-SEM) (Fig. 1) is the result of ten years of experimental work by Australian researcher G. D. Danilatos, followed by a sizable engineering effort financed by a group of US venture capital firms.

Originally conceived as a fairly specialized piece of equipment, the E-SEM has demonstrated its near-universal applicability, combining the high resolution and field depth of the SEM with the flexibility and ease of the light microscope. This long-sought goal has now been achieved through a blending of existing technologies and the serendipitous discovery of a new signal detection method.

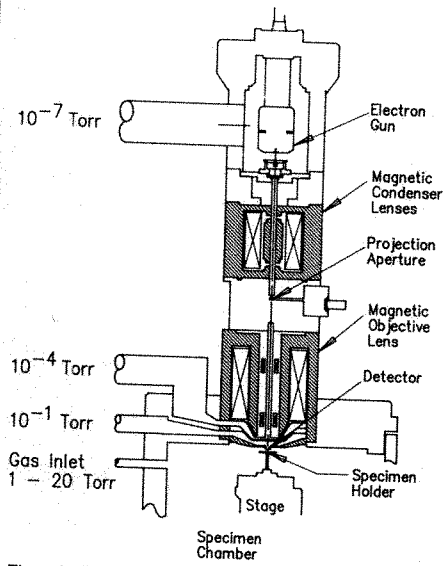

Fig. 1 The optical column and differential pumping system of the environmental scanning electron microscope.

Design hurdles

Designing a scanning-beam instrument to accept any and all specimens presents a number of practical problems. Foremost among these is the necessity to avoid contaminating the clean, high vacuum required in the gun chamber with the moist, high-volatility atmosphere of the specimen chamber. The problem is overcome in the E-SEM through the use of a standard vacuum technique known as differential pumping, in which a series of chambers at increasing pressures along the beam path are linked by small apertures. Dedicated pumps at each stage maintain the required pressure gradient and stop contaminants from reaching the clean upper column. The specimen environment can then be held at pressures exceeding 20 torr (26 mbar), the saturated partial pressure of water vapour at room temperature. At these pressures, wet specimens remain fully hydrated during examination, and liquids may even be observed.

Early studies of electron beam scattering in air led to the assumption that there was little possibility of being able to project a beam fine enough for microscopy through a gas of any significant density. Later re-examination of the problem showed that only a fraction of the beam electrons are scattered into a diffuse 'skirt' if the path length through the high-pressure region is kept short enough, with the remainder of the electrons being left in their original focused trajectories. The surprising result of this finding is that the unscattered beam fraction can still be used to form an image with the same resolution as that obtained in a high vacuum[5]. (The loss in signal-to-noise ratio can generally be made up in other ways.) To make practical use of this result in the E-SEM, it was necessary to place several stages of the differential pumping system inside the final magnetic lens.

Detector development

The development of a secondary electron detector able to operate at elevated chamber pressures was also critical to the success of the E-SEM as a general-purpose imaging tool, because low-energy secondary electrons from the beam impact point are the carriers of the highest-resolution imaging signal[6]. (The usual Everhart-Thornley detector of the high-vacuum SEM cannot be used at these pressures because of unwanted gas ionization and breakdown caused by the high voltage on its scintillator surface.) The E-SEM uses a variation of the gaseous detector device first described by Danilatos in 1982, which involves the gas itself in a signal amplification process[7,8]. Now called the environmental secondary detector (ESD), this simple, compact system is in turn physically integrated into the electron optics and vacuum system.

The new detector takes advantage of the well-understood ionization behaviour of the low-pressure gases found in the E-SEM specimen environment. Gas ionization is induced by a moderate electric field, forcing collisions between highly mobile secondary electrons and neutral gas molecules, resulting in the cascading multiplication of the secondary signal. The slow-moving positive ions present in the gaseous environment also effectively neutralize troublesome surface charging of insulating specimens, regardless of the beam acceleration voltage. Coaxially mounted within the final lens, the detector has perfect symmetry, excellent collection efficiency, and will function with almost any gas.

E-SEM inspection of specially prepared thin-film specimens has shown that at typical operating pressures, the ESD

signal is produced almost exclusively from surface secondary electrons, instead of the higher-energy backscatter electrons which are a large component of the SEM secondary signal[9]. Unlike a SEM detector, the ESD is sensitive to the energy spectrum of secondary electrons, information which is at present lost in a high-vacuum SEM. The ESD is also insensitive to light, allowing red-hot or otherwise light-emitting specimens to be observed easily.

Initial applications of the E-SEM have included dynamic studies of crystal growth, absorption, drying, melting, corrosion and other chemical reactions. The instrument is suitable for the direct observation of paper, plastics, ceramics, textiles, foods, fibres, pharmaceuticals, ores, semiconductors, and many other difficult SEM specimens, including biological samples. □

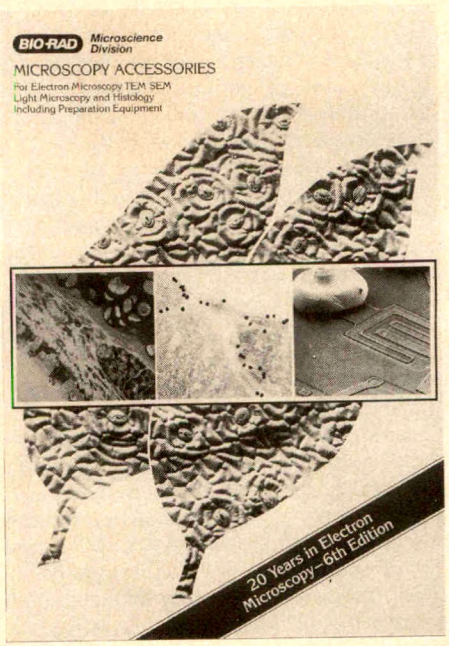
Improving your image

A troubleshooting modem link for EM hardware and a high-sensitivity imaging plate for TEMs are a few of the new ideas for microscopy that can be seen at EMAG-MICRO '89 in London next week.

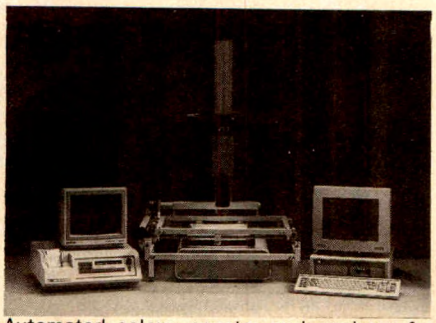
POLAROID (UK) Ltd says its Presentation Copier can at the touch of a few buttons produce full-colour or monochrome **slides, prints and overhead transparencies** from existing micrographs, documents or artwork (*Reader Service No. 101*). The £3,500 (UK) presentation copier, which takes up no more space than a standard desktop copier, has a control panel that can be operated by users with no photographic experience. The system incorporates an auto-winding motorized 35 mm camera back, a pack-film camera back, and preprogrammed settings for five different slide films, colour prints and mini-overheads. The presentation copier accepts all Polaroid instant 35-mm slide films for producing full-colour, black and white, or white-on-blue slides, and two of Polaroid's 3.25 × 4.25-in. instant peel-apart films for full-colour prints and mini-overheads. Polaroid will be exhibiting on stand 46.



Cameca UK Ltd, on stand 2, will be featuring a **telephone modem** that enables SEM hardware to be operated from a remote computer workstation (*Reader Service No. 102*). The company will be demonstrating a computer workstation operating a Cameca SX50 electron microprobe analyser situated in the company's Applications Laboratory in Paris. The modem link facilitates the exchange of data between users and allows remote interrogation of the machine's electronics.

Cameca Ltd's modem link for remote SEM operation.

Apart from the obvious advantages of image data exchange between users, the modem should allow remote fault diagnosis by a field engineer located in the company's support centre, without the need, in many cases, for direct engineer intervention.

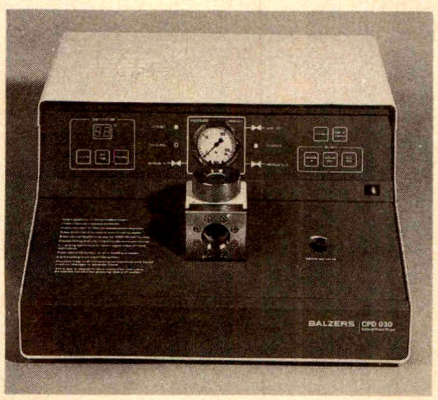


To celebrate 20 years in electron microscopy, Bio-Rad Microscience Division, exhibiting on stand 29, announces its 165-page **catalogue of microscopy accessories** (*Reader Service No. 103*). Divided into 33 sections, the catalogue covers all aspects of microscopy, with specific sections on

Bio-Rad's 20th anniversary edition microscopy catalogue.

SEM and TEM preparation, histology, asbestos sample preparation and immunogold labelling. Other more general sections cover processing chemicals, embedding, ultramicrotomy, metallurgy, calibration aids and preparation equipment.

Analytical Measuring Systems, in collaboration with Microtest Research Ltd, has produced an image analysis system that automates the counting process involved in **Ames bacterial mutagenicity testing** and inhibition zone analysis (*Reader Service No. 104*). The system includes a model 40–10 image analyser, macrostand and lens kit, IBM PC or compatible computer, and plate count analyser software. The system can be used for automated high-speed counting of bacterial colonies on nutrient plates. The software enables the user to carry out a series of statistical analyses on experimental count data, formulate data into tables, calculate mutagenicity increases over controls, display and print graphs and raw data tables, and edit reports. AMS says the system is designed to enable users to re-format reports to suit their own experimental and reporting protocols. Analyti-

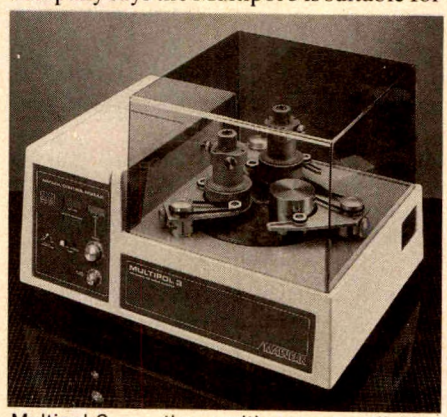


Automated colony counter and analyser for Ames testing from AMS.

cal Measuring Systems will be exhibiting on stand 23.

Sample preparation

Balzers High Vacuum Ltd says its new model CPD 030 **critical point dryer**, which will be exhibited on stand 44, is ideal for drying delicate botanical, zoological or industrial specimens before examination by SEM (*Reader Service No. 105*). Specimens are loaded into the pressure chamber, which is cooled to a preselected temperature of between 2 °C and 12 °C. Large observation windows at the top and side of the specimen chamber allow the user to view the drying process. Liquid CO_2 enters the chamber, is stirred and then partially drained out several times until the specimen is immersed in pure CO_2. The chamber temperature is then increased to between 30 °C and 45 °C, which causes the pressure to rise; at the "critical point" the liquid medium changes



Balzers Ltd's critical point dryer for delicate specimens.

to the gaseous phase and is vented from the chamber. Safety features on the £2,275 (UK) model CPD 030 include a pressure container approved to 200-bar pressure with a bursting membrane at 150-bar pressure.

The model CT 1500 Cryotrans preparation system for **cryoscanning electron microscopy** will be exhibited by Oxford Instruments Ltd on stand 43 (*Reader Service No. 106*). The modular machine comes in two models: the CT 1500B standard system with facilities for gold sputter-coating and carbon evaporation, and the CT 1500C system with a full range of accessories and options. The system uses rapid freezing techniques, which the company says allows specimens to remain fully hydrated with their internal structures preserved. Oxford Instruments says samples can be prepared and viewed in minutes, eliminating the need for time-consuming chemical fixation methods and solvent immersion. Fracturing, sputter-coating, carbon and metal evaporation are carried out in a compact preparation chamber equipped with a nitrogen cooling stage. Oxford says temperature regulation is accurate to ± 0.5 °C and one filling of the liquid nitrogen dewar lasts four hours.

Digitally-controlled operation and programmable sample preparation are features of the Multipol 3 — Malvern Instruments Ltd's three-station **polishing machine** (*Reader Service No. 107*). The company says the Multipol 3 is suitable for

Multipol-3 — the multipurpose polishing machine from Malvern Instruments.

all lapping and polishing methods, including abrasive slurry polishing, and diamond and chemical etches. The machine polishes samples to high degrees of flatness and parallelism, with excellent sample-to-sample consistency, says the company. An extensive range of polishing plates are available: the 300 mm-diameter lapping and polishing plate can handle samples of up to 125 mm in diameter. Over 200 different lapping and polishing protocols can be stored in the system memory, which allows the user to create new protocols or modify existing ones. The Multipol 3 will be on display on stand 45B.

Testbourne Ltd says its Hummer VII **sputter coater** can coat SEM specimens with uniform films with grain sizes of less than 2 nm (*Reader Service No. 108*). The microprocessor-controlled Hummer VII can operate both automatically or manually and can coat specimens of up to 3.25 inches in diameter. When in automatic mode, the user selects the desired film thickness, which can be from 1 to 999 nm, and sets the other operating parameters — no further adjustments of voltage, current or vacuum are necessary. The planar magnetron sputter deposition source produces a cool plasma and can sputter-

The Hummer VII automated sputter coater from Testbourne Ltd.

deposit most precious metal targets, including gold and gold/palladium. The chamber is automatically vented after processing to prevent particulate turbulence. The system offers a pulse deposition mode for fine-grain thin film nucleation, and an etch mode for the surface-cleaning of contaminated specimens prior to sputter coating. The company will be exhibiting on stand 32.

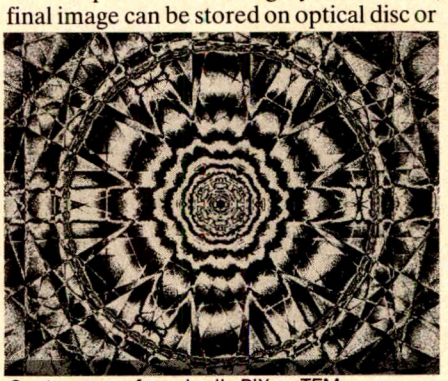
Conjugates

BioCell Research Laboratories has added **1-nm gold conjugates** of goat anti-rabbit IgG and goat anti-mouse IgG to its range of immunogold reagents (*Reader Service No. 109*). The conjuates are used in combination with BioCell's new silver enhancing kits, which amplify the gold signal for antigen detection by light microscopy or immunoblotting. The company says the new conjugates allow increased penetration of cells and tissues without the need for severe permeabilizing procedures. Because the 1-nm gold particles are smaller than immunoglobulins, each can carry several particles with minimal effect on antibody conformity, says BioCell. The silver enhancing kits are insensitive to light and can be stored at 4 °C for at least six months. The gold conjugates are stable for 12 months at 4 °C, and can be stored almost indefinitely when frozen. BioCell will be on stand 28.

Vector Laboratories, exhibiting on stand 8, has a host of **fluorescent and enzymatic reagents** for use in immunohistochemistry, EM, in-situ hybridization, transfer blots and flow cytometry (*Reader Service No. 110*). Fluorescently-labelled streptavidin is available conjugated to fluorescein, Texas Red, phycoerythrin or AMCA — a new blue fluorescent dye. Enzyme-conjugated streptavidin is available labelled with either horseradish peroxidase or alkaline phosphatase. Vector says its streptavidin conjugates are ultrapure and give a high signal-to-noise ratio. For colloidal gold labelling, Vector offers ultrapure streptavidin in an unconjugated form. A selection of affinity-purified anti-biotin and anti-avidin D antibodies in labelled and unconjugated forms are also available.

Fluorescence microscopy

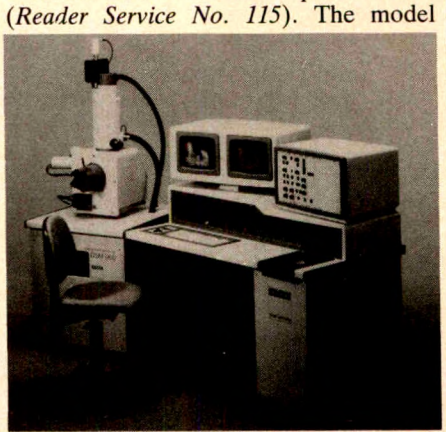
In response to the current popularity of non-disruptive methods for measuring intracellular ion concentration using fluorescent dyes, Nikon UK Ltd now offers a **microspectrofluorimetry system**, which will be on show on stand 24 (*Reader Service No. 111*). The system — developed at Newcastle University — is based on Nikon's Diaphot epifluorescence microscope. It makes use of the Diaphot's short path length and a Nikon beam splitter. When configured for use with a dichroic mirror, the system allows the simultaneous measurement of light emitted at two wavelengths by fluorescent dyes specific for calcium, hydrogen and sodium ions. The machine features a twin-camera port, which allows output from the system to be fed simultaneously to an image analyser and a photon counter. The £20,000 (UK) system can be used to detect intracellular ionic levels and monitor concentration changes across the cell and over time.



Hamamatsu Photonics has an **image processing system** designed specifically for dual-wavelength fluorescence microscopy that can analyse and calculate changes in intracellular ion concentration (*Reader Service No. 112*). The ICMS system includes a low-light level video camera, real-time image processor and IBM/AT PC or compatible computer. Functions performed by the PC include filter changing, image acquisition and analysis, scaling, and the graphic display of results. The system can be used for screening cells before using the zoom function for more detailed analysis. Other uses include studying intercellular communication and creating 2-D displays of a cell to demonstrate local changes in calcium, hydrogen, potassium, and sodium ion concentrations. Hamamatsu says the system's time resolution of three to four pairs of images per second, with a size of 256 × 340 pixels, is more than adequate for many biological applications. The company will be exhibiting on stand 53.

The Hamamatsu image processing system for dual wavelength fluorescence microscopy.

Electron microscopy



To overcome the disadvantages of photographic film as an image-recording material in TEM, Jeol Ltd and Fuji Photo Film Company Ltd have developed an **imaging plate** made of a highly sensitive X-ray recording material (*Reader Service No. 113*). Jeol says the plate is 1,000 times more sensitive than photographic film, and yields a linear response over the full range of electron exposure. The imaging plate is part of the PIXsysTEM, which also includes a TEM with an imaging plate camera, an imaging plate reader/eraser, processor, and printer. Jeol says the imaging plate produces a TEM digital image measuring 102 × 77 mm, with 2048 × 1536 pixels and 4096 grey levels. The final image can be stored on optical disc or printed. After processing, the imaging plate can be erased and reused — eliminating the need for dark-room processing. Jeol will be on stand 18.

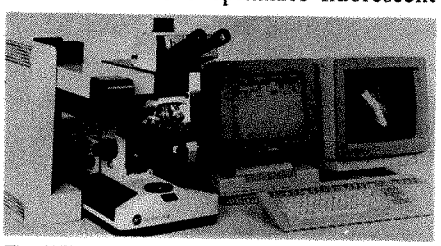
Contour map from Jeol's PIXsysTEM.

Link Analytical Ltd will be showing off its new **EM data management system** — the model eXL (*Reader Service No. 114*). The system features a Pentafet X-ray detector, computer-controlled pulse processor and digital imaging software, which Link says offers powerful electron image acquisition and fast data processing. An extensive range of software is available for quantitative X-ray microanalysis, image analysis, data processing, and full EM automation. The model eXL analytical workstation can be seen in operation linked up to a Zeiss DSM 960 EM, on stand 20.

Science-fiction enthusiasts who have seen "Star Trek V" may be interested to know that Carl Zeiss, Inc.'s model DSM 960 **scanning electron microscope** was used to create some of the film's special effects (*Reader Service No. 115*). The model DSM 960 features a spacious specimen chamber to which detectors for SE, BSE, CL, EDX and WDX spectrometers can be fitted. The digital SEM has microprocessor-control over all operations, including output, stage movements and microscopic functions. A digital framestore allows the operator to view on the monitor what the SEM is seeing, with no "noise" when on slow scan, says the company, and without the need to first capture the image on film. Zeiss will be demonstrating the model DSM 960, which sells for about £78,000 (UK), on stand 4.

The DSM 960 from Carl Zeiss.

Hitachi Scientific Instruments is launching its model S-2700 computerized **scanning electron microscope**, which can be used in a normally lit room (*Reader Service No. 116*). The model S-2700 features Hitachi's conical objective lens, which the company says allows energy-dispersive X-ray analysis and wavelength-dispersive X-ray analysis to be performed at high take-off angles (35 per cent) with improved collection efficiency at a short working distance (12 mm). High-resolution SEM and backscatter photographs can be taken by non-specialists, says Hitachi, because there is no need to change the Z position for X-ray analysis, even for large or highly tilted samples. The SEM is equipped with two built-in frame stores — one of which may be colour — which allow flicker-free TV-scan images to be viewed on the monitor, even when the beam is not on the sample, says Hitachi. The S-2700 can be interfaced with an image analysis system, and can be seen on stand 37.



The model CM20 **scanning transmission electron microscope** from Philips Scientific is based on the optics of Philips' model CM12 and has full 200 kV-power (*Reader Service No. 117*). The system features Philips' patented TWIN lens, which the company says gives high performance in both TEM and probe-forming modes, and a eucentrically tilting goniometer stage and wide range of holders. The CM microprocessor-based control system linking the operator console with the column hardware allows software to be matched to the applications requirements of the user. Philips says the complete CM20 system provides high-resolution in imaging and microanalytical techniques, with facilities for STEM and SEM operation. The model CM20 can be interfaced with TV cameras, X-ray micro-analytical systems and electron spectrometers.

Microscopes and more

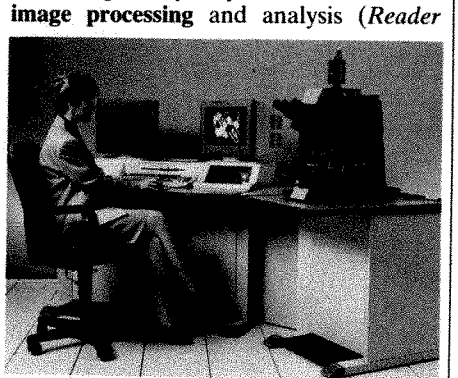
Visitors to stand 55 will be able to see W.A. Technology's **scanning tunnelling microscope** (*Reader Service No. 118*). The STM can image and analyse spectroscopically surfaces on an atomic scale — in air, liquid or vacuum. The system is comprised of a scanning head, electronic con-

trol unit, IBM AT 286/386 or compatible computer with a colour monitor, monochrome frame store and monitor, and dedicated software. The fine metal tip — whose position is controlled by piezoelectric elements — is placed within a few atom diameters of the specimen surface. A voltage applied between the tip and specimen produces a tunnelling current. As the tip scans the surface, its height is adjusted to keep the current constant, and the Z-control voltage provides a readout of the surface profile. Menu-driven software controls most STM functions in both topographic and spectroscopic modes, including parameter setting, running scans or data point samples, and image and data processing.

Wild Leitz will be taking the opportunity to show off its **confocal laser scanning microscope** for 3-D image processing, on stand 3 (*Reader Service No. 119*). The CLSM is based on Leitz's Diaplan microscope, and uses the latest confocal laser technology in combination with a high-resolution image processing system. Leitz says the CLSM is optimized for scanning biological tissues and cell structures, particularly structures with minimum contrast. The CLSM optimizes fluorescent

The Wild Leitz confocal laser scanning microscope.

yield by eliminating stray light and minimizing sample bleaching due to its pulse laser operations, says the company. The microscope can function in reflection and transmission mode, and can be fitted with two channel detectors. The package is rounded off with a wide range of software for 2-D and 3-D image processing, including image filtering, image combinations, densiometry, extended focus, height and contour measurements, 3-D plots, stereo imaging, pseudo-colour, results processing and statistical management.



Olympus Optical will be exhibiting a complete new range of **zoom stereomicroscopes** for use in fields as diverse as biomedicine to semiconductor research, on stand 38 (*Reader Service No. 120*). Key features of the microscopes include newly designed Greenough-type optics, which the company says provide excellent depth of field and image flatness with a large working distance. The company will also be introducing two new student microscopes in the CH series: the CHK and CHL, both of which are equipped with a sturdy metal stand and heavy-duty stage, in order to withstand the rigours of classroom use.

Image processing

Colour Oasis — a full 24-bit **colour archiving system** — will be on display in Sight Systems' stand, number 26 (*Reader Service No. 121*). The £8,000–15,000 (UK) system captures frames of colour video information in analogue format from VTRs, optical and electron microscopes, and video cameras, and converts the information into a high-resolution digital image which is stored on a removable optical disc. Sight Systems says Colour Oasis offers fast archiving and retrieval of up to 880 full-colour images per disc. The system incorporates a new optical disc drive which has a 940-Mbyte capacity. Images are stored in tagged image file format, which the company says is compatible with desktop publishing programs. The system enables users to import high-resolution video images into reports and documents produced by word-processing.

SysTEM — Synoptics' new **image processing and enhancement** system for TEM hardware — will be in action on stand 51 (*Reader Service No. 122*). Designed for operation by non-specialists, sysTEM captures images directly at video rate from a TV camera attached to the TEM. Besides noise reduction, sysTEM produces near-real-time calculations which allow the user to focus and align the TEM accurately. The basic system includes a monitor with a mouse-controlled pointer, the sysTEM unit, and host computer. The computer directs sysTEM in its video rate processing and display operations, provides disc/tape storage of images, executes the Semper 6 plus software program, and can be networked to workstations — each of which can access image archives acquired by sysTEM for off-line processing. Direct on-line image comparisons can be made on sysTEM's screen by importing simulated images from the workstation or host computer.

Cambridge Instruments Ltd, exhibiting on stand 1, announces the Quantimet 570 —an image analysis system for true **colour image processing** and analysis (*Reader Service No. 123*). The company says the programmable image array processor and software is optimized and based on the principles of mathematical morphology, developed in conjunction with the Centre de Morphologie Mathematique in Paris. Stated applications include the analysis of stained tissue sections and polished mineral sections when lit with polarized light. The Quantimet 570 allows the user to distinguish a full range of hues as well as neutral tones. Psuedo-colour modes are available, and the system has 64 full-resolution image frames. Other features include image averaging and integration to reduce "noise", and the capacity for zooming, shrinking and rotating.

Cambridge Instrument's Quantimet 570 image analyser.

Quantel Ltd's Sapphire image processing system now includes software for **measurement and densiometry options** (*Reader Service No. 124*). Both packages offer a range of quantitative and analysis facilities implemented by defining a line or box on the screen for point-to-point or area analysis of luminance distribution; information can be displayed either graphically or numerically. The £1,500 (UK) measurement option provides on-line calibrated measurements directly from the image. Depending upon whether a line or area is defined, operating modes include direct or graphic averaged line or column measurements. Using these basic processes, automated measurements can be performed. The £1,885 (UK) densiometry option is now offered as a result of Quantel's development of real-time shading correction. Quantel will be on stand 35. □

When will biotechnology mature?

Richard Pearson

The science of 'biotechnology' will be judged during the 1990s by what new products are launched, not by promises. But there will still be a demand for qualified workers.

BIOTECHNOLOGY is now entering a critical phase as the multinational chemical and pharmaceuticals companies move closer to the centre of action via a mixture of indigenous growth and selective takeover. In its early days, biotechnology was driven by the push of the scientists and the only constraints were those of feasibility. Now the needs of the marketplace and cost control are paramount.

Progress so far has been rapid, and is expected to continue to be so in pharmaceutical, agriculture and food, but lower oil prices are expected to slow developments in chemicals and the environmental opportunities are still likely to take some years to realize.

Overall the OECD (Organization for Economic Cooperation and Development) sees that the short-term impact on employment is likely to be negative due to rationalizations and cost reductions, with cause and effects often appearing in different continents as Third-World producers for example lose out as crop yields increase. What is seen as certain is the continually rising qualification profile of those working in the industry and the need for the continual updating of skills and retraining[1].

In the United Kingdom, one-third of the new recruits last year to biotechnology work were graduates, while 17 per cent had PhDs and a further 20 per cent had postdoctoral qualifications. Half of these recruits entered work related to bioprocess technology.

The perceived value of doctoral programmes in biotechnology is shown by the way the level of student interest has held up throughout the 1980s despite improving job attractions for first-degree graduates and the falling value of postgraduate grants. Most doctoral students pursued their postgraduate study because of the intrinsic interest of the subject and found places on their own initiative or with the help of their undergraduate supervisor; few were attracted by advertising or the work of the careers services. In contrast, those going on to masters' courses were more likely to see them as an opportunity to gain access to the biotechnology labour market.

Funding

In 1988 there were over 1,100 full-time PhD studentships in biotechnology and around 200 at masters' level. At PhD level, the dominant funding source was the SERC (Science and Engineering Research Council), which accounted for about 45 per cent of the studentships awarded, although only a minority of these were funded through the specialist Biotechnology Directorate, the others being funded through the more general science boards. Non-SERC sources included the other research councils (accounting for about 10 per cent), industry, academic institutions, private and other sources; overseas funds, including those directed through the British Council, accounted for nearly one in five students. This proportion of research-council funding in biotechnology is rather higher than the 35 per cent across all the sciences.

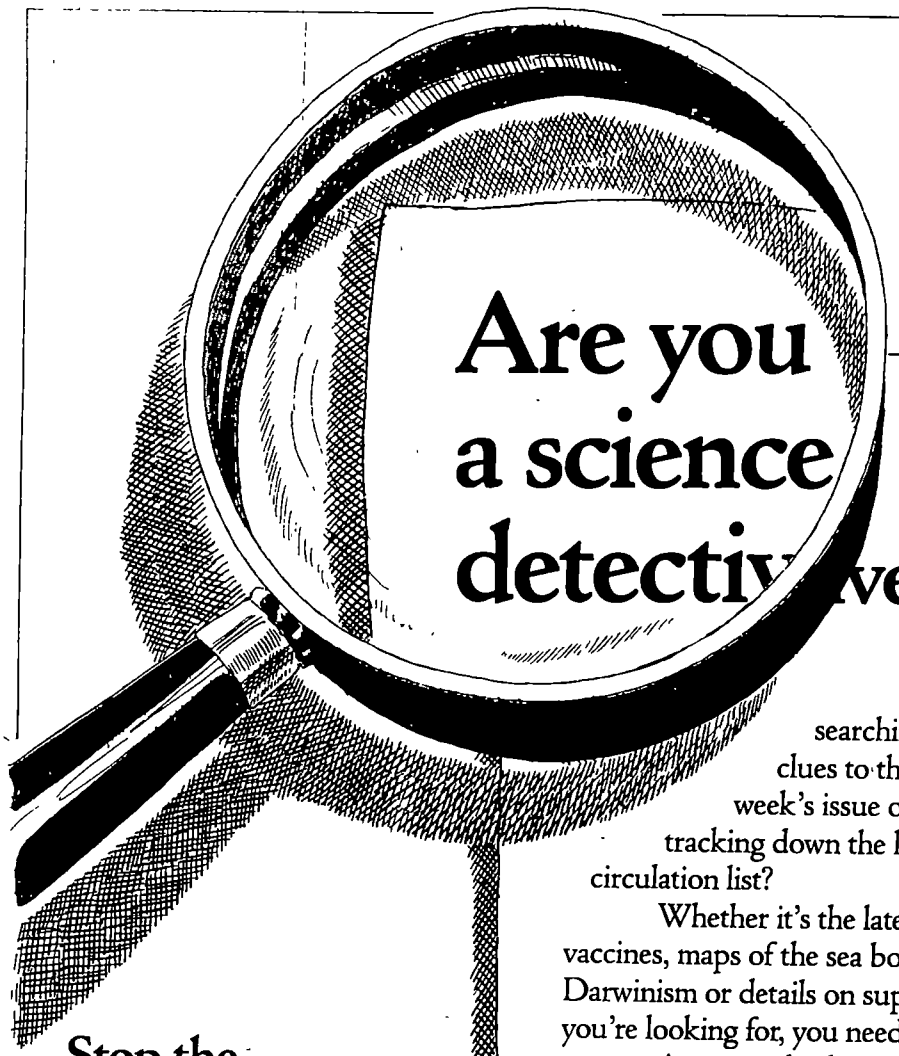
At masters' level, the main funding sources were private funding (one third) while the Training Agency (formerly the Manpower Services Commission) and the British Council each funded approximately 10 per cent of the total. SERC funding was low because it concentrates on support at doctoral level in answer to the needs of industry.

A survey of postgraduates completing their research since 1982 showed that one in three were women, their representation being highest on masters' courses, and that the mean age of all the students was 26. While fewer than 10 per cent of those taking part in PhD programmes had degree classes below an upper second, one in five of those on masters' courses had such degrees. Interestingly a higher proportion of students from sandwich courses were to be found on the PhDs' than on the masters' courses. In terms of source disciplines, biochemistry and microbiology dominated, followed by applied biology and chemistry and chemical engineering.

Once into their postgraduate study, most students found their needs for interest being met, and felt they received a good standard of supervision and provision of training in research techniques. But concern was expressed about the lack of training in team working and there were complaints at the low value of maintenance grants and awards.

The possession of a PhD was seen as an advantage both in getting a job on completion of the course (80 per cent entering biotechnology related employment) and in subsequent performance in it. A masters' degree was seen to be rather less valuable and reflected lack of relevant experience and the weaker demand in the labour market for this qualification, only 66 per cent of those with masters' degrees entering biotechnology-related employment.

Employers reported that skill shortage remained selective and that while the supply of PhDs was growing, the quality seemed to be falling. The range of shortages now also embraces specialists in plant molecular biology, cultures, microbial physiologists and downstream processing. The problems are worst in higher education, where the ability to offer jobs only on short-term contracts and inflexible salary structure are major barriers to recruitment[2].



Management

In addition to a continuing supply of doctoral and postdoctoral graduates, training needs in the future are seen to centre on scientific updating where distance learning will become increasingly important. Following the recent expansion in the supply of short courses, of which more than 75 now exist, provision is thought to be saturated, although there is a need for more specialist, rather large-scale, conferences. There is also a growing interest in management and business-related training and the need to improve the more general induction of new staff into their organization. At a more basic level, biotechnology is also entering secondary school curricula, while a number of undergraduate courses are now under way, although there is little evidence yet of a demand for these specialized courses from industry[3].

In the 1990s and beyond, there will have to be increased investment in training and widening of the skills base if biotechnology is to overcome the market, cost and social challenges and so meet its full potential. □

Are you a science detective?

Do you spend hours searching the library shelves for clues to the whereabouts of this week's issue of Nature or waste time tracking down the last person on the circulation list?

Whether it's the latest developments in AIDS vaccines, maps of the sea bottom, debates on Darwinism or details on supernovae explosions that you're looking for, you need search no longer.

A personal subscription to Nature puts the most recent scientific developments in your hands only hours after the text goes to the printers.

Not only that, but you can read Nature at your leisure without fear of being chased by librarians or colleagues frantic for that one treasured copy.

You can even build up a permanent Nature reference library with its own Nature Index to make the information instantly accessible and ready to hand.

Stop the search now

The University of Queensland

Equal Opportunity in Employment is University Policy

Lecturer in Pharmacology (Fixed Term)

Physiology & Pharmacology Department

The Department is seeking to recruit a pharmacologist with active research interests which complement the current departmental activities in pulmonary pharmacology, sensory and autonomic neuroscience, molecular endocrinology and reproductive biology, immunology and toxicology Some departmental support will available, but the applicant will be expected to have the ability to attract outside funding for his/her research Interaction with other research programs in the Department will be encouraged

The appointment will be expected to participate in the Department's teaching programs in Pharmacology to Medicine, Veterinary Science, Dentistry, Pharmacy and Science students Appointment will be for 5 years with salary in the range of $31,258–$40,621pa

Further information may be obtained from Professor McLachlan (07) 377 3133

Closing Date: September 29, 1989. **Ref. No:** 41989.

Application forms and further details concerning method of application are available from the Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London, WC1H OPF (W6473)A

THE UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF ANATOMY

Lectureship in Cell Biology

Applications for the above post are invited from candidates with proven research potential and the ability to develop an externally funded research programme. Existing research strengths in the Department are within the area of cell biology. Particular interests are cellular and molecular aspects of the development of the immune system (Prof J.J.T. Owen, Dr E.J. Jenkinson, Dr. G.T. Williams) and the role of histone modification in gene expression and cell-cycle progression (Dr. B. Turner). We are seeking candidates with research interests complementary to, or providing additional strengths in one of these areas. The Department is well equipped for cellular and molecular work and has collaborative links with the Departments of Biochemistry, Immunology and Cancer Studies.

In addition to research, a contribution to one of the Departmental teaching programmes in cell biology, developmental biology, histology and topographical anatomy will be required.

Salary in the range £9,260–£19,310 per annum plus superannuation.

Applications, including a proposed programme of research, should be sent to **The Senior Assistant Registrar, The Medical School, University of Birmingham, Vincent Drive, Birmingham B15 2TJ,** from whom further particulars and application forms may be obtained. Informal enquiries may be made in the first instance to the Head of Department Professor J.J.T. Owen F.R.S. (021–414–6812)

Closing Date — 29th September, 1989.

AN EQUAL OPPORTUNITIES EMPLOYER (1475)A

TRAINING OPPORTUNITIES IN
CARDIOVASCULAR RESEARCH
Pre-Doctoral and Post-Doctoral Research Positions

The Department of Physiology and Biophysics at Case Western Reserve University has available several pre- and post-doctoral training positions as part of the Cleveland Training Program in Cardiovascular Research supported by the National Institutes of Health. The training faculty consists of 20 established cardiovascular researchers with state-of-the-art facilities and significant extramural support. The major focus of the program is on cell physiology and metabolism of the heart. Training opportunities exist in a very interactive environment in the areas of intracellular signals, ion transport, molecular biology, protein chemistry, metabolic imaging, neural control, and electrophysiology.

Candidates must be U.S. citizens or permanent residents. Extremely competitive salary, benefits, and tuition packages are available.

For more information contact: Coordinator, Educational Programs, Department of Physiology and Biophysics, Case Western Reserve University, 2119 Abington Road, Cleveland, Ohio 44106, (216) 368-5517, FAX (216) 368-5586.

CLEVELAND TRAINING PROGRAM IN CARDIOVASCULAR RESEARCH

An Equal Opportunity/Affirmative Action Employer.

CASE WESTERN RESERVE UNIVERSITY

(NW4160)A

Research For Drugs In Infection

Post-doctoral vacancies £17,000 - £22,500

ICI Pharmaceuticals is increasing its emphasis on the research for new drugs in infection We wish therefore to appoint two post-doctoral scientists to work in novel and challenging research programmes in bacterial infections.

One will be a biochemist with research experience in some aspect of bacteriology germane to the discovery of antibacterial therapeutic agents Experience in molecular biology and bacterial genetics would be advantageous The successful candidate principally will seek to identify and exploit new targets in bacteria for chemotherapeutic attack.

The second will have appropriate experience in studying aspects of bacterial infections that include host defence, mechanisms of pathogenicity or virulence factors. This part of ICI's approach to the management of bacterial disease will augment and complement the directly antibacterial programmes

An inventive and imaginative approach to the design of 'drugs for tomorrow' will be an important and exciting feature of these jobs which will require the development and testing of feasible ideas that can be translated into drug discovery programmes. Each of the successful candidates will lead a small team of graduate and non-graduate staff within a larger multidisciplinary team of experienced scientists

Our research laboratories which provide professional and technical facilities that are to be envied, are situated in a delightful part of East Cheshire, 15 miles south of Manchester and 20 minutes drive from the Peak District

ICI offers a competitive remuneration package that depends upon the experience of the successful candidates; relocation expenses will be provided where appropriate.

Generally, candidates for either position should have significant and relevant post-doctoral research experience. To apply send a full CV to Ms A. M. Sheard, Personnel Department, ICI Pharmaceuticals, Mereside, Alderley Park, Macclesfield, Cheshire SK10 4TG, quoting reference AMS/TDH/N. A covering letter should be included stating the relevance of your major interests/achievements to the appropriate vacancy outlined here.

ICI **Pharmaceuticals**

(1520)A

Postdoctoral Position
Fred Hutchinson Cancer Research Center

A position is available immediately to study the cell and molecular biology of leukocyte-endothelial cell adhesion Research in progress included the analysis of the structure and function of the murine CD44 and MEL-14 adhesion receptors and their ligands. Experience in molecular biology, immunology or cell biology is necessary. Please submit a letter describing your current and past research activities, your curriculum vitae and two letters of recommendation to:

Tom St. John, Ph.D., Division of Basic Sciences, Fred Hutchinson Cancer Research Center, 1124 Columbia St., Seattle, WA 98104, (206) 467-2871.

FHCRC is an AA/EEO, M/F/H employer. Smoke-free environment.

(NW4138)A

UNIVERSITY OF NORTH CAROLINA AT CHAPEL HILL

ASSISTANT/ASSOCIATE PROFESSOR MOLECULAR BIOLOGY

Tenure track molecular biologist whose research efforts will be dedicated toward generating transgenic animal models pertinent to human diseases. Particular areas of interest can include but are not limited to cystic fibrosis lung disease Qualifications should include an M D. or Ph.D plus at least three years of postdoctoral experience. The primary appointment may be in a basic science or a clinical department. Generous startup funds are available. UNC-CH is an Affirmative Action/Equal Opportunity Employer. Interested candidates should send curriculum vitae, future research plans, and names of four references to: **Dr. Richard C. Boucher, University of North Carolina, Pulmonary Medicine, 724 Burnett-Womack Bldg. CB# 7020, Chapel Hill, NC 27599.**

(NW4147)A

INTERNATIONAL ATOMIC ENERGY AGENCY

seeks

HEAD, ANIMAL PRODUCTION UNIT
for the IAEA Laboratories, Seibersdorf, Austria

Applications are invited for the above post which entails the supervision of a laboratory programme in support of joint FAO/IAEA projects involving the use of nuclear and related biotechnological methods in animal production and health in developing countries.

The candidate should have an advanced university degree in veterinary, animal science or one of the biological sciences and at least 10 years experience in development of techniques (EIA and RIA) for measuring reproductive hormones or diagnosing diseases, or in isotopic methods in animal nutrition and experience in supervising technical and scientific staff.

Tax free emoluments of approx. US$50,000 p.a. Additional allowances if married. Six weeks annual leave. Travel and removal expenses paid. Applicants should send their curriculum vitae quoting Vacancy Notice No. 89/031 to the **Division of Personnel, International Atomic Energy Agency, P.O. Box 100 Wagramerstrasse 5, A-1400 Vienna, Austria** before end of September.

(W6468)A

UNIVERSITY OF LEICESTER

SCHOOL OF BIOLOGICAL SCIENCES
DEPARTMENT OF BOTANY

FOUR POST-DOCTORAL RESEARCH POSITIONS TWO RESEARCH TECHNICIAN POSTS

Applications are invited for four postdoctoral research positions and two associated research technician posts funded by the SERC and the AFRC on the following projects within plant molecular biology and physiology.

1. **Molecular Biology of Phytochrome Assembly (SERC)**
   This project will involve characterisation of the pathway of phytochrome chromophore synthesis, investigation of the attachment of chromophore to apoprotein and the use of transgenic plants to investigate aspects of the assemblyprocess (Postdoctoral Research Associate; Investigator: Dr G Whitelam).
2. **Mechanism of Phytochrome — Mediated Extension Rate and Developmental Pattern in Light-Grown Plants (AFRC)**
   A study of cell wall properties and enzymology, and related changes in gene expression, associated with rapid phytochrome-mediated modulations of extension rate (Postdoctoral Research Associate; Investigator: Professor H Smith).
3. **Analysis of Wound-Induced Gene Expression and Protein Secretion (SERC)**
   Design strategies to allow the secretion of anti-bacterial proteins at wound sites in transgenic plants (Postdoctoral Research Associate; Technician Grade A, Investigators: Dr J Draper and Dr G Whitelam).
4. **Driving Pollen-Specific Transposition of Ds in Transgenic Plants (AFRC)**
   Development of PCR-strategies and the engineering of YAC vector sequences into transposable elements in order to rescue plant DNA sequences flanking transposable element inserts (Postdoctoral Research Associate; Technician Grade C; Investigators: Dr J Draper and Dr R Scott).

Positions are for 3 years from 1st October 1989 or soon as possible thereafter; the Postdoctoral Research Associate positions are on the Research Associate IA scale £10,458–£16,665; Technician Grade A scale £6,040–£6,939; Technician Grade C scale £7,479–£8,645. Applications, including C.V. and names of two referees, indicating which post is being applied for, to: **Professor H Smith, Department of Botany, University of Leicester, Leicester, LE1 7RH,** as soon as possible. Further information is available from the following telephone numbers (area code 0533): Projects 1 and 3: 523396; Project 2: tel 523380; Projects 3 and 4: tel 523392. (1535)A

SCIENTISTS — MOLECULAR BIOLOGY

Applications are invited for two scientists' positions available within the Division of Horticulture and Processing, DSIR. Both scientists will join a well established fruit breeding research programme on apples and kiwifruit. The scientists will be expected to co-ordinate the biotechnology programme with existing research, and develop new collaborative links where appropriate.

One scientist will be employed on a project to elucidate and modify apple characters such as colour, flavour and keeping qualities using molecular techniques.

One scientist will be employed to establish transformation systems for New Zealand apple cultivars, and investigate gene expression after transformation.

Work has been initiated in both projects.

Candidates must have a PhD. A strong background in recombinant DNA technology is sought. An initial three year contract could lead to permanent employment. Salary will be determined by the qualifications and experience of the individual candidate. Applicants should submit a letter of application and curriculum vitae, with names of two potential referees to:

The Personnel Officer,
DSIR,
Private Bag, Auckland,
New Zealand.

Applications close on the 15th October 1989.

UNIVERSITY OF WALES COLLEGE OF MEDICINE
DENTAL SCHOOL
LECTURESHIP IN BASIC DENTAL SCIENCE

Applications are invited from suitably qualified persons for a NAAS funded Lecturer in the Department of Basic Dental Science

Candidates with a research background in either molecular biology, cell and structural biology of mineralised tissues or the pathogenesis of connective tissue disease are encouraged to apply.

Salary according to experience and qualifications but it is expected that the starting point will be within the range £10,458–£12,381 on Grade A of the Academic Salary scale. The full scale being £10,458–£15,372 with the possibility of progression to Grade B, £16,014–£20,469

Further particulars (quoting ref. No. DS/4/89) may be obtained from the **Assistant Registrar of the Dental School, University of Wales College of Medicine, Heath Park, Cardiff, CF4 4XY** (Tel. No. 0222/755944 ext. 2469) to whom full Curriculum Vitae including the names and addresses of three referees should be sent within three weeks of the appearance of this advertisement.

Prospective applicants may also contact Professor G Embery (ext 2544) for further details. (1509)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)
DEPARTMENT OF IMMUNOLOGY
POSTDOCTORAL SENIOR RESEARCH OFFICER

A Post-doctoral position is available immediately for a study on the HLA gene associated with increased susceptibility to multiple sclerosis. This is a collaborative project involving the HLA laboratories in the Department of Immunology, at the Royal Postgraduate Medical School (Professor J R Batchelor, Dr R I Lechler) and the Institute of Neurology, Queen Square, London (Professor W I McDonald, Dr D A Francis). The project, which is supported for 3 years by the Multiple Sclerosis Society, is to extend a previous observation in which a new allele of HLA-DQA was found to have a raised frequency in patients with multiple sclerosis. The successful applicant will be engaged in nucleotide sequencing, and synthesizing allele specific oligo-nucleotide probes to be used for study of patients with varying clinical forms of the disease. Experience in HLA genetics and recombinant DNA techniques will be advantageous.

Application forms and further particulars are available from the **Personnel Office, Royal Postgraduate Medical School, DuCane Road, London W12 0NN** quoting ref: AIVB.

Closing Date. 21 September 1989. (1489)A

BIOCHEMISTS
ENTOMOLOGISTS
MOLECULAR BIOLOGISTS

Plant Science Research, Inc., a subsidiary of BioTechnica International, Inc., is an agricultural biotechnology company involved in developing improved varieties of important agricultural crops. Plant Science Research (formerly the plant research subsidiary of Molecular Genetics, Inc.) has been a leader in plant biotechnology and breeding for over 9 years and maintains state-of-the-art research facilities in the Minneapolis metropolitan area and a series of plant breeding stations throughout the Midwest. The company's products are marketed throughout BioTechnica Agriculture's commercial seed companies.

Plant Science Research is seeking candidates for current and upcoming positions in PLANT BIOCHEMISTRY to conduct biochemistry and cell culture related research for purposes of product and technology development; PLANT MOLECULAR BIOLOGY to conduct recombinant DNA manipulations, transformations of plants, and analyses of transgenic plants; and ENTOMOLOGY to develop and implement bioassays of potential insecticides and transgenic plants expressing insecticide genes.

Qualified applicants for these positions will have an M.S. or B.S. and must have several years of relevant research experience beyond the degree. Plant Science Research, Inc. offers a multidisciplinary research and development environment and a competitive salary and benefits package. Applicants should submit a resume and a list of 3 references to the attention of Human Resources at:

Plant Science Research
10320 Bren Road East
Minnetonka, MN 55343

An Equal Opportunity Employer

(NW4135)A

THE UNIVERSITY OF BRITISH COLUMBIA

DEPARTMENT OF CHEMISTRY

ASSISTANT PROFESSORSHIP

The Department of Chemistry, University of British Columbia, invites applications for a tenure-track assistant professorship in experimental physical chemistry, starting July 1, 1990. Preference will be given to candidates who propose to carry out research in molecular dynamics, interactions, or interfacial phenomena; however, outstanding candidates in related areas of experimental physical chemistry will be considered. A Ph.D., postdoctoral experience, and a strong research track record are required. The successful candidate would be expected to teach chemistry courses at the undergraduate and graduate level. The salary will be commensurate with education and experience.

The University of British Columbia offers equal opportunity for employment to qualified female and male applicants. The position is subject to final budgetry approval and, in accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents.

Applications consisting of a curriculum vitae, list of publications, summary of research interests, a detailed research proposal, and the names and addresses of at least three references should be sent to: **Larry Weiler, Professor and Head, Department of Chemistry, University of British Columbia, 2036 Main Mall, Vancouver, British Columbia, Canada, V6T 1Y6.**

Closing date for applications will be December 1, 1989.

(NW4154)A

Department of Agriculture and Rural Affairs
Victoria, Australia

LIVESTOCK IMPROVEMENT UNIT
MOLECULAR GENETICIST
SCI–4

Salary Range — $41,579-$44,018

Commencing salary will be assessed according to qualifications and experience

DUTIES:

To compliment its strength in quantitative genetics, the Livestock Improvement Unit has recently formed a molecular genetics section which will undertake research in the use of molecular biology for the genetic improvement of livestock species. The successful applicant will lead this section and is expected to contribute to existing projects on mapping genes affecting quantitative traits, and to develop new projects.

QUALIFICATIONS:

Mandatory: An appropriate degree or diploma in Agricultural Science, Science or an equivalent qualification.

Desirable: A Ph.D or equivalent in molecular genetics or molecular biology. Interest in the application of this knowledge to genetic improvement of livestock. Ability to lead a research team.

For further information and a copy of the Duty Statement and Selection Criteria contac: Dr M Goddard on telephone 61-3-6517218 or fax 61-3-6517006 or the address for applications.

Written applications are invited from women and men, quoting position number 05/05/0775/1 and giving details of qualifications, experience and the names of three referees.

Applications must reach

Manager, Personnel
Department of Agriculture and Rural Affairs
PO Box 500
East Melbourne, Australia 3002

by close of business on 4.10 89.

(W6461)A

British Geological Survey

ADVISERS IN THE OIL AND GAS EXPLORATION SECTOR

INDONESIA

The British Geological Survey invites applications for advisory posts in the following disciplines:

1 **Senior Reservoir Engineer**
2 **Enhanced Oil Recovery (EOR) Specialists (2 posts)**
3 **Reservoir Geologist/Formation Evaluation Engineer**
4 **Core Analyst**
5 **Organic Geochemist**
6 **Palynologist**
7 **Sedimentologist**

The posts will be located in Jakarta where the Advisers will be attached to a continuing programme of Technical Cooperation with the Indonesian Government's Research and Development Centre for Oil and Gas Technology (LEMIGAS). The programme is designed to strengthen LEMIGAS' capabilities in the areas of basin analysis and reservoir engineering, to enable it to provide an effective service to government and industry. The British contribution is funded by HM Government's Overseas Development Administration (ODA) under bilateral technical cooperation arrangements, and the project is managed on ODA's behalf by the BGS.

The Advisers should have a good honours degree in an appropriate discipline. They will be involved in the training of LEMIGAS personnel, and in the development of LEMIGAS laboratories, including advising and assisting in the formulation and implementation of relevant systems and experimental programmes. Limited fieldwork will be involved where appropriate. The Advisers will be responsible to the ODA/BGS Project Co-ordinator in Jakarta.

The appointments will be for a period of two years exclusive of generous fare-paid annual leave for the officers and their families, who may accompany them to Indonesia. Posts 1 to 4 above will be effective from 1 April 1990 (mobilisation late March), Posts 5 to 7 from 1 November 1989 (mobilisation late October).

Jakarta offers good housing, international schooling, an active social life, and the opportunity to live and work in a different and fascinating environment.

The Advisers will benefit from an attractive remuneration package. Salaries will be in the range of **£23,383** to **£29,920** per annum for the post of Senior Reservoir Engineer and **£15,534 to £24,356** for the other posts, depending on qualifications and experience. There is a non-contributory pension scheme. Mobilisation and cost of living allowances are payable. They are subject to review and depend on salary, marital status and family circumstances. They are currently in the range **£3,938 to £9,554** per annum, with additions for children and education costs. Free housing and medical care is provided.

For an application form you should write, telex or fax to the following address, quoting Ref. LEM/OD/89/1:- Establishments (Recruitment), British Geological Survey, Keyworth, Nottingham, NG12 5GG. Telex: 378173 BGSKEY G, Fax: 06077 6602. Please make it clear for which post(s) you are applying. Further information is available from Dr J. D. Bennett at the above address. Telephone: Plumtree (06077) 6111.

The closing date for receipt of completed application forms is 22nd September 1989.

The Natural Environment Research Council is an equal opportunities employer.

MEDICAL RESEARCH COUNCIL
BIOSTATISTICS UNIT
5 Shaftesbury Road, Cambridge CB2 2BW

Senior Statistician

Applications are invited for a career non-clinical scientific post with the Medical Research Council. The post is tenable at this Unit in the first instance. Preference will be given to senior statisticians with wide experience of working in the Biomedical field.

The incumbent would be expected to take an active part in the unit's developing programme in statistical epidemiology, which includes studies of cancer, dementia and AIDS, and provide research leadership to younger statisticians working in the field.

The position may be filled at either the senior or special appointment level. The latter is equivalent to the University professorial level. Remuneration will be at an appropriate point on the scales for university non-clinical academic staff. MRC Pension Scheme. 30 days annual leave plus public holidays and 2.5 privilege days. Sports facilities at the Addenbrooke's site.

Further information may be obtained from Dr N Day, Director of the Unit, Tel: (0223) 324022.

Applications including a full CV and the names and addresses of two professional referees should be sent by 29 September 1989 quoting reference BSU/SS, to:

MOLECULAR EVOLUTION

The Department of Ecology and Evolution at The University of Chicago announces a search to fill a position in the area of molecular evolution/variation. The appointment may be at any level.
Please send a letter of application, curriculum vitae, reprints and/or recent manuscripts, a statement of research interests, and have three letters of recommendation sent to: **Molecular Evolution Search committee, Department of Ecology and Evolution, The University of Chicago, 915 East 57th Street, Chicago, IL 60637.** Deadline for receipt of applications is October 20, 1989.
Affirmative Action/Equal Opportunity Employer. (NW4139)A

DEAN

College of Natural and Agricultural Sciences
University of California, Riverside

The Dean oversees the Land-Grant mandate in teaching, public service, and research in the College and normally serves as the Director of the Division of Agriculture and Natural Resources (DANR) on the Riverside campus, including the Agricultural Experiment Station. The College has 15 academic departments and research units containing 240 ladder-rank FTE, 30 other academic FTE, and 475 non-academic staff FTE. The annual College/DANR budget is over $30 million. The campus is growing rapidly and is surrounded by a supportive and rapidly growing external citizenry.

Applicants must have a distinguished record of research, teaching and service appropriate to an academic appointment at the level of full professor in the College department of the candidate's discipline as well as a record of successful leadership and creative management. Salary will be commensurate with experience and qualifications. The negotiable target starting date is July 1, 1990.

A curriculum vitae and the names and addresses of six references are required from each applicant. The search will continue until the position is filled.

The University of California, Riverside is an equal opportunity/affirmative action employer. Women and minorities are encouraged to apply.

Nominations and applications will be reviewed starting October 1, 1989 and should be addressed to:

Professor Irwin P. Ting, Chair
Search Committee for the Dean
Office of the Chancellor
University of California, Riverside
Riverside, CA 92521.

UBC RESEARCH ASSOCIATE AND POST-DOCTORAL FELLOW

Applications are invited for a faculty position at the University of British Columbia, at the level of Research Associate in the Department of Medical Genetics. This well funded, established group is studying the molecular basis for Huntington disease and investigating the molecular pathology of human lipoprotein lipase deficiency with particular emphasis on mutation analysis and gene therapy. Applicants should have a PhD degree with research experience in molecular biology.

Inquiries are also invited from recent recipients of a PhD who wish to have further training in the molecular pathogenesis of human genetic disease.

RESEARCH ASSISTANT

Applications are invited for a technician to join this group studying molecular pathogenesis of human genetic disease. Applicants should have at least a BSc degree and experience in molecular biology.

Salary for this renewable position will be commensurate with experience. In accordance with Canadian Immigration requirements, this advertisement is directed at Canadian Citizens and permanent residents.

Interested applicants should send a Curriculum Vitae with names of three referees by 15 October 1989 to: **Dr Michael R Hayden, Department of Medical Genetics, F168 – University Hospital, 2211 Wesbrook Mall, Vancouver, BC V6T 2B5 CANADA. Phone (604) 228-7738.** (NW4203)A

FACULTY POSITIONS
SECTION OF IMMUNOBIOLOGY
YALE UNIVERSITY

The Section of Immunobiology, a multidisciplinary group working collaboratively on basic problems of T cell development, activation, and function, seeks applicants for several faculty positions at the level of assistant professor in the general area of immunobiology.

Qualified applicants in all areas of Immunology are invited to apply and would be expected to develop an independent research program using molecular, cell biological or biochemical approaches to immunobiological problems. We are particularly interested in people active in the areas of T cell development, regulation of gene expression, signal transduction, and protein traffic in cells of the immune system. They will also be expected to particpate in departmental teaching at primarily the graduate level.

Candidates should submit a curriculum vitae with a summary of present and future research interests, and request that three letters of recommendation be sent, all of which must be received at the below address no later than November 15, 1989.

Dr. Richard Flavell
Chairman, Section of Immunobiology
Yale University School of Medicine

Women And Minority Candidates Are Encouraged To Apply
(NW4161)A

Faculty Position
in Structural and Cellular Biology

The Department of Structural and Cellular Biology of the University of South Alabama College of Medicine is seeking applications for a tenure track position at the Assistant Professor level to begin in spring or summer 1990. The Department currently has ten full time well funded faculty, who are working in the areas of cellular biology, molecular biology, endocrinology and neuroscience. We are seeking individuals with postdoctoral experience, and research background in the use of molecular and cellular biology methodologies to study important questions in neuroscience. The areas of interest would include, but not be restricted to, the molecular basis of synaptic transmission, vesicular release, brain regeneration and repair, axonal transport, control of neurite extension, neurotransmitter synthesis and regulation, and function of the neural cytoskeleton. Candidates would be expected to establish a well funded research program.

Our department is responsible for teaching medical courses in Neuroanatomy, Gross Anatomy, Embryology and Histology, as well as graduate courses in Cell Biology and other related disciplines. We are particulary interested in individuals who can contribute to our teaching of Medical Neuroanatomy and graduate Neuroscience.

Competitive salaries and start-up funding are available. Applicants should submit, prior to November 1, 1989, curriculum vitae, statement of current and planned research interest, and letters from at least three references. Expression of interest is particularly invited from qualified women and minority candidates.

Send formal applications to:
Dr. Steven R. Goodman, Chair
Department of Structural and Cellular Biology
College of Medicine, Room 2042 MSB
University of South Alabama
Mobile, Alabama, 36688.

CENTRE NATIONAL DE LA RECHERCHE SCIENTIFIQUE

GROUPE DE LABORATORIES DE L'INSTITUT DE RECHERCHES SCIENTIFIQUES SUR LE CANCER
PARIS FRANCE

POST DOCTORAL RESEARCHER (Cell Biology, Immunology)

Applications are invited from scientists holding a PhD degree with a strong experience in cellular biology and immunology. Field of research will concern "The regulation of eukaryotic gene expression". Murine interferons (IFN)α and ß cloned and sequenced in the laboratory are presently studied and constructions to make inducible foreign genes using promoting and enhancing regions of these IFNs genes are under study. The applicant should be a motivated person with interest in this program and should have i) tissue culture/specificity, ii) and/or polyclonal and monoclonal antibody production iii) and/or translated protein experience and knowledge. The appointment would be initially for one year. The salary range depend on age and experience. Applications enclosing a complete curriculum vitae and a list of publications, as well as the names and addresses of two referees, should be sent to: **Dr. DOLY Janine, I.R.S.C.-C.N.R.S. Biologie Moléculaire des Interférons, B.P. No 8, 94802** – VILLEJUIF Cédex, France. (W6469)A

INSTITUTE OF PSYCHIATRY
(University of London)
DEPARTMENT OF NEUROLOGY

POSTDOCTORAL RESEARCH FELLOW

IMMUNOCHEMICAL ANALYSIS OF ABNORMAL PROTEINS IN MOTOR NEURONE DISEASE

A grant has been awarded by the Motor Neurone Disease Association for three years to study the molecular pathology of ubiquitinated inclusions in Motor Neurone Disease, with the aim of clarifying the molecular basis of neuronal damage in this condition. The project will involve the immunochemical analysis of postmortem tissue, including microdissection of damaged neurones and inclusions. The postdoctoral fellow will join an established team at the Institute of Pscychiatry (Professors P.N. Leigh and B.H. Anderton) and will collaborate with Dr M. Swash and Dr J. Martin at the London Hospital. Ideally, experience in protein biochemistry will be an advantage, but should not be regarded as essential.

Salary: On research assistant grade 1A (salary range £9,816–£12,381 pa plus £1,650 London Weighting).

The post is available from 1 October 1989.

Applications in the form of curriculum vitae and names of two referees should be sent to the **Assistant Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF** from who further particulars are available. (1508)A

CANCER PHARMACOLOGIST

The Kenneth Norris Jr. Comprehensive Cancer Center at the University of Southern California is seeking to recruit a pharmacologist with expertise in molecular aspects of antineoplastic drug therapy and clinical applications. Applicants should have training as a pharmacologist and be interested in molecular analysis of drug action. The appointment will be at the level of Associate Professor in the Department of Biochemistry. Applicants should also be interested in liaising with the ongoing clinical programs at the Cancer Center and be involved in the design and development of new treatment protocols, etc. Interested individuals should submit their curriculum vitae together with three references to: **Dr. Peter A. Jones, Director for Basic Research, Kenneth Norris Jr. Comprehensive Cancer Center, 1441 Eastlake Ave., P.O. Box 33800, Los Angeles, CA 90033-0800.** Affirmative Action/Equal Opportunity Employer. (NW4178)A

TENURE-TRACK OPENING

DEPARTMENT OF BIOLOGY, U.C.L.A., PLANT CELL/DEVELOPMENTAL BIOLOGY

at the molecular level. The position is in the Division of Molecular, Cell, and Developmental Biology in the department, and involves participation in the interdepartmental Plant Molecular Biology Group. Potential research areas of interest include plant/microbe interactions, regulation of reproductive development, signal transduction mechanisms, and hormonal regulation of development, but other relevant areas will also be considered. Applicants should be committed to making a substantial contribution to teaching as well as to developing a strong and innovative research program.

Submit curriculum vitae, a statement of research and teaching interests, and have three letters of recommendation sent to: **Dr. E. M. Tobin, Chair, Search Committee, Biology Dept., U.C.L.A., Los Angeles, CA 90024** by December 1, 1989.

U.C.L.A. is an EO/AA Employer, and we encourage applications from women and members of minority groups. (NW4143)

FACULTY POSITIONS
THE WAKSMAN INSTITUTE
RUTGERS, THE STATE UNIVERSITY OF NEW JERSEY
MOLECULAR AND DEVELOPMENTAL BIOLOGY

Applications are invited for two tenure-track faculty positions at the Waksman Institute with joint appointment in the Department of Molecular Biology and Biochemistry. The rapidly expanding research-orientated environment of Rutgers University includes the adjacent Center for Advanced Biotechnology and Medicine and the Robert Wood Johnson Medical School. Successful applicants will be expected to conduct vigorous independent research programs, and to participate in instructional activities. Preference will be given to candidates whose research programs concern the developmental biology and molecular genetics of *Drosophila,* yeast, or filamentous fungi. Recently renovated laboratory space and generous start-up funds are available.

Candidates should send biographical sketch with list of publications, description of research interests, and names of three references to. **Dr. Joachim Messing, Director, The Waksman Institute, Rutgers, The State University of New Jersey, P.O. Box 759, Piscataway, NJ 08855-0759.** *Rutgers University is an Equal Opportunity/Affirmative Action Employer.* (NW4196)A

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF MEDICINE

The following posts are available within the Department, in the group whose principal research interest is the immunology and pathogenesis of persistent virus infections (Professor J.G.P Sissons, Dr L K. Borysiewicz, Dr. J H Sinclair).

Senior Research Associate — to work on defending the specificity of the cytotoxic T cell response for peptide epitopes of human cytomegalovirus

Research Associate — to work on the specificity of the cytotoxic T cell response to VSV

Applicants should possess a PhD and preferably have previous experience in the areas of immunology or microbiology.

Stipend £12,381–£15,372 according to age, qualifications and experience

Work in the group is supported by an M.R.C Programme Grant and by other research funds, in newly built and equipped laboratories. Further details available from **Professor J.G.P. Sissons and Dr. L.K. Borysiewicz, Department of medicine, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QQ** (Telephone Cambridge (0223) 336849) to whom applications should be sent by 28 September 1989.

(1492)A

Retinal Developmental Neurobiologists

The Lions' Sight Centre at the University of Calgary Faculty of Medicine offers one or more full-time positions in Cellular or Molecular Developmental Neurobiology of the Vertebrate Retina. Candidate(s) should have a PhD, or MD with equivalent research training; at least two years postdoctoral experience; and an established record of productive and fundable research in cellular, biochemical or molecular biology of retinal development, cell culture, transplantation or regeneration.

A renewable five-year scholar appointment will be available on successful application to the Alberta Heritage Foundation for Medical Research and/or the Medical Research Council of Canada. Salary and academic rank will be commensurate with experience.

The successful candidate(s) will hold a faculty appointment in an appropriate department and will be affiliated with the Lions' Sight Centre and the Neuroscience Research Group. Interdisciplinary collaborations will be encouraged, and 75% of time will be protected for research.

In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada, The University of Calgary has an Employment Equity Program and encourages applications from all qualified candidates, including women, aboriginal people, visible minorities, and people with disabilities.

Please send curriculum vitae, summary of research interests, and names of three references by October 15, 1989, to:

Dr. W. K. Stell
Director, Lions' Sight Centre
The University of Calgary
3330 Hospital Drive N.W.
Calgary, Alberta T2N 4N1 (NW4137)A

The William Harvey Research Institute
of St Bartholomew's Hospital Medical College

DIRECTOR
Professor Sir John Vane FRS
Deputy Director
Professor Erik Änggård

Charterhouse Square
London EC1M 6BQ
Telephone: +44-1-253-8393
Fax: +44-1-251-1685

The Institute was created 3 years ago and now has a staff of over 20, including 6 senior scientists, 4 overseas visitors, PhD students and technicians. It is financed by Glaxo Group Research.

Our interests are focused on the endothelial cell and its control of the cardiovascular system. We expect to make biological discoveries that will lead to new concepts for the control or prevention of cardiovascular disease.

WE ARE NOW ENTERING A PHASE OF EXPANSION

In about 10 months' time, substantial laboratory space will become available on the Charterhouse Square campus, when the preclinical departments of St Bartholomew's Hospital Medical College move to new quarters.

The William Harvey Research Institute expects to become part of a Research Centre, which will concentrate on drug discovery in the fields of cardiovascular disease and inflammation. Other groups already committed to the concept will be led by Professor G.V.R. Born, FRS, Professor R.J. Flower, Professor D. Tomlinson and Professor D. Willoughby.

We have, then, a unique opportunity to build a strong and active centre of excellence in the biological and clinical sciences. Those interested in participating in this exciting opportunity should write to one of the scientists named above.

Posts available immediately in the William Harvey Research Institute are:

Pharmacologist

— A senior scientist to lead the in vitro laboratory. The ideal candidate should have at least four years of post doctoral experience, should be well versed in working with cells and isolated tissues, and preferably have an interest in endothelial cells and their products. Salary on the Lecturer B scale £17,664-£22,119, inclusive of London allowance.

Biochemical Pharmacologist

— Senior scientist to lead the biochemical laboratory. The ideal candidate should be thoroughly familiar with standard biochemical techniques and concepts and have a sound understanding of biochemical modes of drug action. Salary on the Lecturer B scale £17,664-£22,119, inclusive of London allowance.

Biochemist

— A postdoctoral position in biochemical pharmacology. A likely candidate may have completed a PhD in biochemistry relating to eicosanoids, peptides or intracellular signalling.

Salary on Research Assistant 1A scale £12,109-£18,315, inclusive of London Allowance.

Applicants should write to Professor Sir John Vane.

(1531)A

University of Alberta
Edmonton

Dean
Faculty of Pharmacy and Pharmaceutical Sciences

The University of Alberta invites applications and nominations for the position of Dean of the Faculty of Pharmacy and Pharmaceutical Sciences. Located in Edmonton, Alberta, the University of Alberta is a comprehensive public university with an enrolment of approximately 30,000 full-time and part-time students. The appointment will take effect July 1, 1990 or as soon as possible thereafter.

The Faculty of Pharmacy and Pharmaceutical Sciences offers a four-year undergraduate program leading to the Bachelor of Science in Pharmacy Degree. Programs leading to the M.Pharm, M.Sc., and Ph.D. degrees in various disciplines in Pharmacy are also available. Current enrolment is approximately 420 undergraduate students and 45 graduate students. There are 20 full-time academic staff and 12 support staff. The Faculty also maintains a strong research program including cooperative projects with the Faculty of Medicine, University of Alberta Hospitals and the Cross Cancer Institute, in addition to an international collaborative research program.

The Dean is responsible to the Vice-President (Academic) for the supervision and administration of the academic program, budget, and all activities of the Faculty. Candidates should have a demonstrated capacity for collegial leadership, strong academic qualifications, and proven administrative ability. Knowledge of pharmacy in Canada is desirable.

Written nominations or applications for the position, accompanied in the latter case by a resume of qualifications and experience, and the names of three referees, should be submitted by November 30, 1989 to:

Dr. J. Peter Meekison
Vice-President (Academic)
Third Floor University Hall
University of Alberta
Edmonton, Alberta, Canada
T6G 2J9

The University of Alberta is committed to the principle of equity in employment.

(NW4153)A

UNIVERSITY OF EDINBURGH
AFRC CENTRE FOR ANIMAL GENOME RESEARCH

The newly-established Interdisciplinary Research Centre on the King's Buildings site of the University of Edinburgh is seeking Senior Group Leaders and Scientists to participate in the research programme of the IRC. The IRC has been established as a separate cost-centre within the University and is funded by an initial 10-year grant from the Agricultural and Food Research Council, subject to satisfactory progress and review. There will be a centrally-funded staff of approximately 40 scientists, technical and administrative staff, 25 resident externally-funded staff, and up to 25 part-time and visiting scientists.

Research at the Centre will focus on the use of transgenic animals as experimental models to address questions of particular relevance to fundamental genetics, agriculture and medicine, and will be closely associated with established academic research groups in the Edinburgh area. A large in-house transgenic mouse facility will be completed in early 1990 together with laboratories devoted to molecular biology, embryo stem cell manipulation (gene targetting) mouse genetics and mammalian cell culture.

SENIOR GROUP LEADERS, MOLECULAR GENETICS

Group Leaders will be responsible for the initiation and follow-through of major research programmes in a field that makes advantageous use of transgenic biology and its applications. Group Leaders, responsible to the Director, will be expected to pursue a vigorous independent research programme within the remit of the Centre. Collaborations with outside academic or industrial groups will be encouraged. Suitable candidates will have a number of years of postdoctoral research experience in a relevant field and will have a proven scientific track record. Research group management experience would be an advantage.

SCIENTISTS, GENETICS AND MOLECULAR BIOLOGY

The Centre is seeking scientists at all levels with an interest in transgenic biology and related fields to participate in the research programme. Candidates will have a first degree in a relevant subject area and at least two years postgraduate scientific experience. A Ph.D. would be an advantage.

Applications: Salaries will be at an appropriate point within the University scales for Research Council Staff and may be subject to negotiation. Applications (6 copies, 1 copy from overseas) together with a CV and the names of 2 referees to be sent, before Friday, 29 September, to the **Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS.** Applications made after this date will be considered on an individual basis. *Please quote reference no. 5702.*

(1526)A

UNIVERSITY OF MINNESOTA

NEUROSCIENTIST
FACULTY POSITION

The Department of Neurosurgery at the University of Minnesota seeks a faculty member whose research emphasizes cellular or molecular neurobiology. Areas of interest include but are not limited to brain tissue grafting and neuro-oncology. Successful candidate should have interests compatible with the clinical and basic science research programs of the Department of Neurosurgery. This position will be a full-time position at either the rank of Assistant Professor on tenure-track or Associate Professor with tenure. Faculty rank will be commensurate with degree of experience. It is expected that the applicant will hold a joint appointment in the Department of Cell Biology and Neuroanatomy. Also, it is anticipated this individual would become actively involved in the Graduate Program in Neuroscience and participate in the instruction of graduate and professional students in the health sciences.

The candidate must hold an M.D. or Ph.D. degree, and should present a record of productivity and distinction in cellular or molecular neuroscience research and should be capable of obtaining funding for research programs through national agencies. The individual should have demonstrated effectiveness in teaching in an academic medical institution.

Send letter of application, curriculum vitae and three references to: **Dr. Timothy J. Ebner, Chair, Search Committee, Department of Neurosurgery, Box 96 UMHC, University of Minnesota, 420 Delaware St. S.E., Minneapolis, Minnesota 55455.**

Closing date for application is October 15, 1989. Appointment will occur by July 1, 1990, or as soon as the appointee is available.

The University of Minnesota is an equal opportunity educator and employer, and specifically invites and encourages applications from women and minorities.

(NW4171)A

BIOCHEMICAL INSTRUMENTS/SALES SUPPORT

Scientific instrument company in New Jersey is seeking an indiv., w/a bkgd. in Biochemical Science. Strong customer interaction in product development and training. Experienced in biomedical applications. Knowledge of fluorescence spectroscopy, circular dichroism, cation measurement systems desired. Some travel required.

Send résumé with salary desired: **Personnel, SPEX INDUSTRIES INC, 3880 Park Avenue, Edison, NJ 08820–2419.**

Equal Opportunity Employer.
(NW4172)A

ECOLOGIST

The Department of Biology at the University of Rochester invites applications for a tenure-track position in behavioral, population, or community ecology. Although the appointment is likely to be made at the level of Assistant Professor, applications from outstanding senior-level individuals are encouraged. The successful candidate will be expected to develop an excellent research program and exhibit a commitment to high quality undergraduate and graduate level education. Postdoctoral experience is preferred. Send *curriculum vitae*, a statement of research interests, and three letters of recommendation by **30 November** to: **John Jaenike, Ecology Search Committee, Department of Biology, University of Rochester, Rochester, New York 14627.** The University of Rochester is an Affirmative Action/Equal Opportunity Employer.
(NW4157)A

EMBRYOLOGIST/ CELL BIOLOGIST:

The Reproductive Endocrine Section, Department of Ob/Gyn invites applications for a Ph.D. to pursue independent research and direct an IVF laboratory. Candidates should have special interest in the reproductive sciences, especially the molecular biology of early development and embryo manipulation. Rank and salary are commensurate with qualifications. Forward curriculum vitae to: **Paul McDonough, Department of Ob/Gyn, Medical College of Georgia, Augusta, GA 30912.** *The Medical College of Georgia is an Affirmative Action/Equal Opportunity Employer.* (NW4170)A

British Geological Survey

DIRECTOR

Nottingham up to £35,400

The Natural Environment Research Council is seeking a Director of the British Geological Survey to succeed Mr Geoffrey Larminie, OBE, upon his retirement in December 1989. The Director will be responsible to the Director of Earth Sciences, NERC, for the scientific leadership and management of BGS which has a staff of about 750 at its headquarters in Keyworth (Nottingham), Edinburgh, and four small regional offices. The annual budget of BGS is about £24m.

Applicants should have an international reputation in the Earth Sciences and significant experience in the management of geological personnel and projects. Experience of working with both industry and government will be an advantage.

Starting pay on appointment will be on the scale £34,095 to £35,415, with a further increment to £38,210 depending on performance. A non-contributory pension scheme is available, plus a generous annual leave allowance. Some assistance towards relocation costs may be available.

Application forms and further information may be obtained from Lorraine Nowlan at the address given below or by telephoning (0793) 411531. Arrangements can be made for short-listed candidates to visit BGS Keyworth. Completed applications, including a full CV should be sent to Lorraine Nowlan, NERC, Polaris House, North Star Avenue, Swindon, Wilts. SN2 1EU, by 30th September 1989.

The Natural Environment Research Council is an equal opportunities employer.

Natural Environment Research Council

(1503)A

FACULTY POSITION in EXPERIMENTAL PHYSICAL CHEMISTRY

The Department of Chemistry at Washington University in St. Louis invites applications for a tenure-track position, effective September, 1990. Primary consideration will be given to applicants at the Assistant Professor level, but candidates with distinguished records will be considered for higher-level appointments. Candidates should submit, by November 1, 1989, a curriculum vitae and a description of proposed research, and arrange to have three letters of reference sent to: **Professor Dewey Holten, Chairman, Physical Chemistry Search Committee, Department of Chemistry, Washington University, St. Louis, MO 63130.** Washington University is an Affirmative-Action, Equal Opportunity Employer, and employment eligibility verification will be required of the successful candidate.
(NW4169)A

UNIVERSITY OF LEICESTER

Department of Biochemistry

POSTDOCTORAL RESEARCH ASSOCIATE (Molecular Biology)

Applications are invited for a postdoctoral position available for three years from 1 October 1989. The project, funded by the Medical Research Council, involves cloning the genes of a eukaryotic multifunctional complex. Experience of working with DNA and of molecular biology techniques would be an advantage.

Salary on the RA 1A scale £10,458 to £16,665 a year, according to qualifications and experience.

Applications (including a c.v. and the names of two referees) should be sent as soon as possible to **Dr. A.J. Rivett, Department of Biochemistry, University of Leicester, Leicester LE1 7RH,** from whom further details of the post and of the research programme may be obtained by telephoning (0533) 523462. (1500)A

INSTITUTE OF HYDROLOGY
WALLINGFORD, OXON

GROUNDWATER HYDROLOGIST

We are seeking a Groundwater Hydrologist to join the Consulting Group of the Institute. This group undertakes applied projects for clients in the UK and overseas.

The post will offer the opportunity to be involved in a range of research and applied studies and to work independently on other assignments overseas. It will include particular responsibility for applying computing techniques to assist groundwater resource and hydrological impact studies, mainly involving unconsolidated aquifers.

Applicants will require a good honours degree in geology or related subject, preferably a post graduate qualification in hydrogeology and must be competent with FORTRAN and familiar with personal computers. Some experience overseas would be an advantage but is not essential.

The appointment if for three years in the first instance. Salary will be in the range of £10,678 per annum to £14,909 per annum, or £13,254 per annum to £18,864 per annum, depending on qualifications and experience. Generous holidays and non contributory pension scheme. The Institute of Hydrology is a competent organisation of NERC.

Further information and application forms may be obtained from **Sue Fenton, Institute of Hydrology, Wallingford, Oxon, OX10 8BB**. Telephone 0491-38800. Closing date for applicants is 28th September 1989. Previous applicants need not apply.

NERC is an Equal Opportunities Employer.

Natural Environment Research Council

(1514)A

ASSISTANT/ASSOCIATE PROFESSOR OF LABORATORY ANIMAL PATHOLOGY

Department of Veterinary Pathology, University of California, Davis

Candidates must have a D.V.M. (or equivalent) and a Ph.D. with advanced training in pathology. Board certification by the A.C.V.P. is required. Candidates must have special competence in laboratory animal pathology. Persons also certified by the A.C.L.A.M. are encouraged to apply. There should be evidence of productivity in research relating to pathogenesis of diseases of laboratory animals or development of animal models of human disease. The successful candidate will be expected to be competent in the use of techniques necessary for studies at the cellular and molecular level.

The candidate will participate in relevant teaching programs at the professional and postgraduate levels, including service duties for UCD Laboratory Animal Facilities. An important goal will be to establish an independent research program. Rank and salary will be commensurate with qualifications. Starting date is 7/1/90. Deadline for receipt of applications is 12/15/89 or until filled.

Applicants should send curriculum vitae and the names of at least three references to **Dr. D.L. Dungworth, Chairman, Department of Veterinary Pathology, University of California, Davis, California, 95616.**

The University of California is an Affirmative Action/Equal Opportunity Employer.

(NW4175)A

AUSTRALIA
CSIRO
SOIL ZOOLOGIST
A$31,525 pa To A$45,699 pa
DIVISION OF SOILS
ADELAIDE–AUSTRALIA

CSIRO Division of Soils seeks a Soil Zoologist to join a group investigating the effects of earthworms on soil structure and fertility.

The appointment will be for five years.

Applicants should have a PhD or equivalent with research experience in soil macrobiology.

The Project is in association with CSIRO Division of Entomology and Flinders University with Financial support from the Australian Wool Research Council.

Selection Criteria and Duty Statement are available from the Personnel Officer ph: (08) 274–9206 FAX: (08) 338–1636. Further information can be obtained from Dr. K. Lee., Ph: (08) 274–9311.

Applications quoting Ref No: A5299 addressed to: The Chief CSIRO Division of Soils, Private Mail Bag No. 2, Glen Osmond, S.A. 5064, Australia.

Close on 10 October 1989.

CSIRO is an equal opportunity employer. (W6459)A

UNIVERSITY OF NEW SOUTH WALES
Sydney, Australia
LECTURER IN BIOCHEMISTRY
(Tenured/Tenurable Appointment: Ref. 1137)

Applicants should have a relevan PhD and post-doctoral exper ience. The appointee will b expected to teach biochemistry t undergraduate students in Scienc and Medicine and to undertake research program, including th supervision of postgraduat students.

The School of Biochemistr contains a wide range of moder equipment, including high spee ultracentrifuges, scintillatio counters and sensitive spectro photometers. It is well equippe for high performance liqui chromatography and has recentl acquired a fast protein liqui chromatography (FPLC) system Other equipment includes a Applied Biosystems DNA syn thesizer and on IRIS 4D/7 graphics workstation The Schoo has a major share in two moder nuclear magnetic resonanc spectrometers, viz. Bruker CXP 300 and AM-500. There is als access to first class mass spectro metry facilities.

Current research strengths i the School are in the areas of bio chemical parasitology, molecula biology, nuclear magnet resonance spectroscopy and plan biochemistry and tissue culture Applicants with experience in an area of biochemistry are welcom although it could be an advantag to be associated with one of thes four developed areas.

The position is available fror January 1990 and appointmer will be either with tenure or on th basis of a contract with provisio for conversion to tenure.

Further information is availabl from Professor W J O'Sullivar Head of School (tel. (02) 697 203 or fax (02) 662 2918). Applicatio close: 28 October 1989.

Salary: A$31,259 rang A$40,622 Commencing salar according to qualifications an experience.

Applicants should forward tw copies of: written applicatio curriculum vitae; transcript academic record (quoting refe ence number, business hou telephone number, together wit the names and addresses of tw referees) to the Academic Sta Office, PO Box 1, Kensingto NSW Australia 2033.

Equality of employme opportunity is University policy.

JOHN INNES INSTITUTE

Genetics Department

Higher Scientific Officer and Scientific Officer positions in Genetics.

The following are available:

1. HSO to study the molecular genetics of homoeotic mutations affecting flower development in *Antirrhinum* (E Coen and R Carpenter) (GEN404).
2. HSO to study the role of myb-oncogene-related genes in *Antirrhinum* development. (C Martin) (GEN402).
3. HSO to study the molecular genetics and biochemical basis of specificity in the recognition between *Rhizobium* and its host legumes. (J A Downie and A W B Johnston) (GEN400)
4. SO to assist with the analysis of the molecular genetics and biochemical basis of recognition between *Rhizobium* and its host legumes. (J A Downie and A W B Johnston) (GEN401).
5. SO to assist with the genetic analysis of mutations caused by transposable elements in *Antirrhinum* (R Carpenter and E Coen) (GEN405)

Further details on each of these posts can be obtained from the Departmental Secretary, Genetics Department, John Innes Institute, quoting the relevant reference number.

These period appointments will be to the HSO scale £10,678 to £14,335, and SO scale £9131 to £11,709. Non-contributory superannuation. Equal Opportunities Employer.

Applications, including cv and the names of two referees should be sent to the Personnel Officer, John Innes Institute, Colney Lane, Norwich NR4 7UH, UK to arrive not later than 30 September 1989. Please quote relevant reference number.

The John Innes Institute is associated with the AFRC Institute of Plant Science Research.

(1480)A

MICROBIOLOGIST

South Oxfordshire

Salary Range £11K – £21K

This is an opportunity to play a key project management role in the development of biological methods to produce energy from biomass

The Energy Technology Support Unit (ETSU) at Harwell acts on behalf of the Department of Energy in the management of a wide range of biofuels projects Studies cover the full breadth of fundamental scientific investigations within universities to full scale commercial implementation of new processes We need a microbiologist or environmental scientist to formulate and co-ordinate new programmes in consultation with universities, government departments and industry, primarily in the UK but also through various international collaborative arrangements

You will be working as part of a multidisciplinary team, but would need the initiative and judgement to make an individual, specialist contribution This is a high profile post, in which you will be required to give both technical and general presentations to a wide range of audiences Highly developed interpersonal skills and an ability to communicate effectively are therefore essential As well as having a good honours degree it would be advantageous to have previous experience of anaerobic microbiology and of project management within an industrial/research environment

The appointment may be on either a permanent or fixed term basis We offer attractive salaries in the range £10,875 to £20,995 depending on your capabilities and experience, with the possibility of further progression beyond £24,560 based on good performance Assistance with relocation expenses may also be given

For an application form please write to Mrs L Martindale, Recruitment Branch, AEA Technology, Harwell Laboratory, Didcot, Oxon, OX11 0RA. Alternatively please phone Abingdon (0235) 432059 (24 hours).

Please quote reference number (N) 1941

The closing date for applications is 29th September 1989

We are an equal opportunities employer

AEA TECHNOLOGY

(1501)A

UNIVERSITY OF CAMBRIDGE

LECTURESHIP IN ZOOLOGY

Applications are invited for a Lectureship in the Department of Zoology. Applicants should have a research interest in the field of cell biology, preferably in the cytoskeleton or a related area.

The appointment to the lectureship will be for 3 years, with the possibility of reappointment to the retiring age. The scale of stipends for a University Lecturer not originally resident in College is £14,169 pa, rising by eleven annual increments to £21,850.

Further information may be obtained from **John Andrews, Secretary to the Appointments Committee for the Faculty of Biology 'A', Department of Zoology, Downing Street, Cambridge, CB2 3EJ** (Tel: 0223 336621) to whom applications (twelve copies) including a *curriculum vitae*, a list of publications, statement of intended research and the names of not more than three referees, should be sent so as to reach him not later than 14 October 1989.

(1512)A

THE UNIVERSITY OF WARWICK

DEPARTMENT OF BIOLOGICAL SCIENCES

POSTDOCTORAL FELLOW

Applications are invited from Microbiologists to study the role of bacteria in the oxidation of methane in anaerobic environments with particular attention on landfill sites. The successful candidate will be expected to isolate, identify and quantify the bacteria responsible and to eventually study the physiology and biochemistry of the organisms with particular emphasis on the methane oxidation enzymes.

The post is funded by the UKAERE Harwell Energy Technology Support Unit for two years and is available immediately (or by negotiation). Salary will be on the Research IA scale: £10,458 to £16,665 pa. Further particulars can be obtained by telephoning Professor H Dalton (0203-523552 direct line). Application forms from the Executive Officer, Department of Biological Sciences, University of Warwick, Coventry, CV4 7AL, quoting Ref. No UKAERE/HD/14. Closing date: 28 September 1989.

AN EQUAL OPPORTUNITIES EMPLOYER

(1528)A

UNIVERSITY OF CALIFORNIA
DAVIS

DIRECTOR OF THE INSTITUTE FOR ENVIRONMENTAL HEALTH RESEARCH

Applications are being sought for the position of Director of the Institute for Environmental Health Research This organized research unit, one of several on campus, will have the responsibility for the development and coordination of campuswide programs in toxicology and related areas. The Director will hold a joint administrative and academic 11 month appointment in an appropriate department as a tenured faculty member The Director reports directly to the Vice Chancellor for Research

Applicants should be nationally and internationally recognized for their scholarship in toxicology or closely related areas, should have demonstrated ability to secure funding for research development, and an ability to provide strong leadership. The incumbent will be expected to deal effectively with diverse groups including faculty, students, administrators, industry and government. Commitment to the affirmative action goals of the campus is essential.

In addition to the development of a strong research and academic program in the Director's area of expertise, the incumbent will be responsible for strategic planning and further development of campwide programs in toxicology, for the administration of facilities of the Institute (approximately 40,000 sq. ft.) and for the enhancement of the campus' numerous programs in toxicology.

Letters of application are requested as soon as possible and preferably by 1 October 1989. A *curriculum vitae* and names and addresses of three references should be submitted with the application Requests for confidentiality will be honoured. The position will remain open until filled. Applications should be submitted to:

Robert D. Grey, Dean
Division of Biological Sciences
376 MRAK Hall
University of California
Davis, CA 95616
(916) 752–6764
(916) 752–2604 (FAX)

The University of California is an Affirmative Action/Equal Opportunity Employer. (NW3950)A

DEVELOPMENTAL AND CELL BIOLOGY

TWO TENURE-TRACK FACULTY

THE UNIVERSITY OF

ARIZONA

TUCSON ARIZONA

As part of a continuing expansion, the Department of Molecular and Cellular Biology anticipates hiring two faculty members in 1990. Preference will be given to applicants with research interests in developmental or cellular biology of multicellular organisms, although exceptional candidates in other areas will be considered. Candidates at the junior (Assistant) and senior (Associate/Professor) levels will be considered. Successful candidates will be housed in new laboratory space currently under construction. They will be expected to establish a competitive research program and teach at the undergraduate and graduate levels

Send CV, a 1–2 page statement of research interests, and have at least three supporting letters sent to: **Professor Samuel Ward, Head Department of Molecular and Cellular Biology, Biosciences West Building, Room 308, University of Arizona, Tucson, AZ 85721, USA.** Application deadline is October 15, 1989, or until positions are filled

The University of Arizona is an Equal Opportunity Affirmative Action Employer. Women and minorities are encouraged to apply. (NW4074)A

SEARCH FOR

DEAN OF GRADUATE SCIENCES

The Baylor College of Medicine, a private free-standing institution, invites applications and nominations for the position of Dean of Graduate Sciences.

The Dean of Graduate Sciences will be responsible for the quality and advancement of all aspects of Graduate Science Degree programs. The Dean for the Graduate Sciences will report directly to the President of the College. The Dean will work to:

- ★ Stimulate, support, develop, and coordinate Graduate Science programs;
- ★ Provide leadership to the Graduate faculty in developing educational and scholarly activity;
- ★ Participate in fundraising efforts in support of Graduate Science programs;
- ★ Develop and implement creative programs to recruit and retain Graduate students; and,
- ★ Represent the Graduate School in national organizations and to oversee the general well being of the Graduate programs.

Candidates for the position must have a Ph.D. or equivalent; have administrative experience with Graduate education; have a strong commitment to academic excellence, and possess effective oral and written communication skills.

Nominations and applications, including a current curriculum vita, should be forwarded to:

Antonio M. Gotto, Jr., M.D., D.Phil., Chairman
Search Committee–Dean of Graduate Sciences
Baylor College of Medicine
Department of Medicine
6535 Fannin–Suite A654
Houston, Texas 77030

Baylor College of Medicine is an equal opportunity, affirmative action employer. (NW4206)A

CHAIRPERSON

Department of Meteorology

University of Maryland, College Park

Nominations and applications are invited for the position of Chairperson of the Department of Meteorology at the University of Maryland at College Park. Since the previous search, the state has mandated the enhancement of the College Park campus to make it into the flagship campus of the University System. The chairperson will be expected to contribute to this enhancement by attracting high-quality faculty for additional tenure-track and tenure positions, by providing imaginative leadership, and by promoting the department in the emerging national and international atmospheric and oceanographic science programs. The candidate should possess a doctoral degree and a record of excellence in scholarly achievements.

Applications should be accompanied by a curriculum vita and the names of four references. Send to: **Dr. Donat G. Wentzel, Meteorology Chair Search Committee, Astronomy Program, University of Maryland, College Park, MD 20742.** To be assured of full consideration, applications should be received by October 15, 1989. *EOE/AAE.* Women and minority candidates are encouraged to apply.

(NW4088)A

ORGANIC/SYNTHETIC CHEMISTS

(3 POSITIONS)

$31,525 p.a. to $45,699 p.a.

DIVISION OF CHEMICALS AND POLYMERS
CLAYTON, VIC.

GENERAL: The CSIRO Division of Chemicals and Polymers aims to develop new technologies to support the growth in Australia of chemical, polymer and water/wastewater treatment industries which are competitive in domestic and international markets. The Division employs approximately 170 people of whom 60 are professional scientists. It is located in modern well-equipped laboratories at the CSIRO Clayton site

THE JOB: We are currently seeking highly motivated chemists for our Bioactive Chemicals Program. Two vacancies exist in the Chemical Processing project where appointees will be expected to research and develop synthetic chemistry for industrial production, using both conventional and revolutionary technology. A further vacancy exists in the Agricultural Chemicals project where you will have the opportunity to explore novel and innovative organic chemical syntheses

Appointees will conduct research within broad guidelines, allowing for flexibility of approach and the opportunity to explore new chemical techniques

THE PERSON: Applicants should possess a Ph.D degree or equivalent qualification in any branch of synthetic chemistry, plus a proven record of achievement in independent research. Sound written and oral communication skills are a prerequisite, along with the ability to work as a team member

TENURE: A fixed term appointment of 3 years. An indefinite appointment may be considered in the case of an outstanding applicant in the field. Australian Government Superannuation benefits are available

FURTHER INFORMATION: A detailed information package is available on request from Dr G. Simpson, phone (03) 542 2519. Details of current and proposed research projects will be provided.

Selection criteria and job description are available from Ms J Pickering, phone (03) 542 2483

APPLICATIONS: Stating relevant personal and professional details including the names and addresses of at least two referees and quoting reference no. 89/9 should be addressed to:

The Chief,
CSIRO Division of Chemicals and Polymers,
Private Bag 10,
Clayton, Vic. 3168

by 3rd November, 1989. (W6467)A

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

ASU 89/9

UNIVERSITY OF OXFORD

UNIVERSITY OF OXFORD IN ASSOCIATION WITH ST. EDMUND HALL

UNIVERSITY LECTURERSHIP IN PHYSICAL GEOGRAPHY

Applications are invited for the above post, funded under the UGC's New Academic Appointments Scheme and tenable from 1 October 1990, stipend on the age-related scale £10,458-£12,852. The successful candidate may be offered a fellowship at St. Edmund Hall. Further particulars may be obtained from:

Miss C.M. Godman,
Secretary, Board of the Faculty of Anthropology and Geography,
c/o The Oriental Institute,
Pusey Lane,
Oxford OX1 2LE
(telephone 0865 278210)

to whom 10 copies of formal application (one only from overseas candidates), naming three referees, should be sent not later than 1 November 1989.

Dyson Perrins Laboratory

Applications are invited for a postdoctoral position to perform research on mechanistic studies related to the biosynthesis of penicillins and cephalosporins.

This work is part of a substantial multi-disciplinary international collaborative research effort.

Applicants should have training in synthetic organic or bioorganic chemistry.

Appointment will initially be for one year with the possibility of renewal.

Salary on the scale £10458-£12381 p.a. dependent on age and experience plus USS.

Those interested should write to **Professor J. E. Baldwin, The Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY** enclosing a full curriculum vitae and the names and addresses of two referees as soon as possible. (1495)A

The University is an Equal Opportunity Employer

University of London

CHAIR OF PHILOSOPHY OF NATURAL SCIENCE TENABLE AT KING'S COLLEGE LONDON

The Senate invite applications for the above Chair, tenable in the research-oriented Department of the History and Philosophy of Science at King's College London. The successful applicant will have produced outstanding work in the philosophy of modern natural science or mathematics, and will be expected to provide academic leadership.

Applications (10 copies) should be submitted to the **Teachers' Section (N), University of London, Malet Street, London WC1E 7HU,** from whom further particulars should first be obtained.

The closing date for receipt of applications is 6 November 1989. (1534)A

THE ROCKEFELLER UNIVERSITY

POST-DOCTORAL RESEARCH ASSOCIATES needed to work on organelle biogenesis and developmental regulation of transcription and RNA processing in trypanosomes and related protozoa. The recent development in this laboratory of DNA transfection methodology for trypanosomatids has opened up an enormous range of new possibilities.

THE AMERICAN LEGION BRAIN SCIENCES CHAIR

The American Legion Brain Sciences Chair is a newly-endowed position at the University of Minnesota in basic neurobiological research. We seek an outstanding candidate who will be appointed to a full-time Tenured position at the University of Minnesota at either the Professor or Associate Professor level. Duties will be to teach Graduate/Postgraduate level in Brain Sciences and to establish a major research program in the fundamental neurosciences at the Minneapolis Veterans Administration Medical Center. This laboratory will address central issues of neuroscience and disease pathobiology (for example, synaptic receptors and their role in normal and disturbed brain function), and may involve molecular biology, physiology, pharmacology, anatomy and/or biochemistry. The opportunity to make two or more junior appointments associated with the Brain Sciences Chair, along with the allocation of appropriate laboratory space, developmental funds, and administrative support will provide a well-established investigator with the resources to create a broad research program within an expanding neuroscience community at the University of Minnesota. Minimum requirements for Associate Professor level include M.D. and/or Ph.D. with professional distinction in research and writing and demonstrated effectiveness in teaching and advising. Minimum requirements for Professor include M.D. and/or Ph.D. plus national reputation in research and evidence of leadership in candidate's professional field. Salary is negotiable. The last date for receipt of applications is 11/30/89 with appointment 1/1/90 or ASAP. Applicants should respond with CV to:

Dr. Richard W. Price
Chairman, Search Committee
The American Legion Brain Sciences Chair
Department of Neurology, Box 295 UMHC
University of Minnesota Medical School
Minneapolis, MN 55455

The University of Minnesota is an equal opportunity educator and employer and specifically invites and encourages applications from women and minorities. (NW4183)A

SENIOR NEUROBIOLOGIST/NEUROSCIENTIST

National Institute of Mental Health
Intramural Research Program

The NIMH is accepting applications for a senior neurobiologist/neuroscientist with interests in studying basic brain mechanisms of behavior. Applicants must hold a doctoral degree or equivalent and be interested in joining an established research program involving behavioral neurophysiology, neuroanatomy, neuropsychology, developmental neurobiology, neuroethology and other disciplines. The laboratory facilities are located in a rural setting approximately 30 miles west of the main NIH Bethesda campus near the town of Poolesville, Maryland. Researchers in the fields of neurophysiology, neuroanatomy, experimental psychology (including physiological psychology), developmental neurobiology, and related fields in the brain and behavioral sciences are especially encouraged to apply. Excellent facilities exist for primate research. The successful candidate should have broad experience and established credentials in the neurosciences. Duties will include scientific leadership and administration of a laboratory, as well as conduct of an internationally-recognized research program. Salary will be commensurate with other NIMH researchers having similar responsibilities, approximately $57,158 to $75,500 plus full Federal benefits. Send C.V., bibliography, a statement of future research directions, and the names of three references to:

SENIOR RESEARCH SCIENTIST

BIOCHEMIST/MOLECULAR BIOLOGIST

Berkshire

Celltech is one of Europe's foremost biotechnology companies and a leader in the design and large-scale production of proteins for therapeutic and diagnostic use With a number of exciting candidate therapies already in development, Celltech's status as an autonomous and influential force in the pharmaceutical industry is assured

We are now looking for an accomplished life scientist to participate in our drug discovery programme Working closely with academic collaborators and Celltech's own scientists, you will apply modern molecular biology techniques and molecular modelling to unravel details of the structure and function of pharmaceutically important proteins

You must be qualified to PhD level in life sciences, with an emphasis on protein structure and function. Ideally, you will already have some experience of molecular biology and molecular modelling and will be motivated to use these techniques to probe details of protein conformation You must have 1-3 years' post-doctoral experience in academic or industrial environments and a proven track record in research. A willingness to work in multi-disciplinary teams is essential.

A competitive salary will be supported by a comprehensive benefits package which includes pension scheme, free life assurance and, if appropriate, relocation assistance. Career development prospects are excellent, with promotion avenues to senior positions in research as well as general management.

Please write with full details of your qualifications and experience to Mrs Jane Smith BSc C BIOL MI BIOL, Celltech Limited, 216 Bath Road, Slough, Berkshire SL1 4EN, quoting reference 199

THE UNIVERSITY OF CALIFORNIA SAN DIEGO DEPARTMENT OF BIOLOGY FACULTY POSITION

The Department of Biology at the University of California, San Diego invites applications for one tenure-track position at the assistant professor level. We are seeking out-standing candidates in three main fields: 1) mammalian molecular biology/animal virology or related areas, 2) cellular biology with emphasis in one or more of the following subdisciplines: protein sorting, signal transduction, cell-cell interactions, extra-cellular matrix or cell motility, 3) developmental genetics. Ph.D. and several years of postdoctoral experience are required.

We will consider exceptional applicants in all areas of cellular biology, developmental genetics, mammalian molecular biology and animal virology. We strongly encourage applications from women and minority groups.

Salary will be commensurate with level of appointment and based on the published UC salary scale. The successful candidate is expected to develop a vigorous research program in one of the rapidly-moving areas mentioned above, and participate in undergraduate and graduate teaching/training.

Please submit curriculum vitae, a statement of present and future research goals, and names of three references by October 31, 1989 to: **Search Committee, Department of Biology, B-046, University of California, San Diego, La Jolla, CA 92093.**

The University of California, San Diego is an equal opportunity/affirmative action employer.

(NW4200)A

THE UNIVERSITY OF MINNESOTA

Senior Faculty and Institute Fellow in Large Scale Computing

The University of Minnesota invites applications and nominations to fill several senior faculty positions in large scale computing. Depending on the qualifications of the candidates, these tenured faculty positions will be based in one or more departments at the University. The persons appointed will, in addition to having regular faculty appointments, become Fellows of the Minnesota Supercomputer Institute, which is a research program at the University.

A successful candidate must hold a Ph.D., have at least two years experience in a relevant setting, and have demonstrated outstanding research accomplishments and intellectual leadership in a disciplinary or interdisciplinary area of large scale computing. Recruited candidates will have substantial achievements meriting tenure in an appropriate department. Preference will be given to candidates at the full professor level with programs of demonstrated excellence and originality in supercomputer research, especially those which show promise to complement existing programs at the Institute.

Faculty rank and remuneration are dependent upon experience, qualifications, and accomplishments. Deadline for applications is January 15, 1990. Inquiries, nominations, and applications should be directed to:

Professor H.T. Davis
Search Committee Chair
Minnesota Supercomputer Institute
1200 Washington Avenue South
Minneapolis, MN 55415

The University of Minnesota is an equal opportunity educator and employer and specifically invites and encourages applications from women and minorities.

STAFF MEMBER

Los Alamos National Laboratory, a worldwide leader in scientific research, is seeking an individual for its Life Sciences Division.

Responsibilities include conducting research in biochemistry, physiology and molecular biology of trace metal tolerance and degradation of toxic organic molecules in higher plants. Individual will also develop methods for practical application and environmental limitation as well as study the structure function relationships in metal bindings compounds.

Position requires significant recent experience in isolation and chemical characterization of metal-binding polypeptides and other secondary metabolites produced by plants. Experience in enzymology and study of biochemical processes necessary for synthesis for these compounds is essential as well as familiarity with methods of differential screening of genes involved in metal tolerance. Experience in different aspects of plant tissue culture desirable. A PhD in biology, botany or biochemistry and at least two years of postdoctoral research studying biochemical or molecular mechanisms of metal tolerance in higher plants or equivalent combination of education and work related experience is required.

For consideration, please send resume to: Ray Archuleta (MS P280), Personnel Services Division 90600-DT, Los Alamos National Laboratory, Los Alamos, NM 87545.

Affirmative Action/Equal Opportunity Employer. Must be able to obtain a Department of Energy Security Clearance.

DEMONSTRATOR

Applications are invited for th post of Demonstrator in t Department of Biochemistry a Genetics, tenable for a period three years. Applicants shou possess a PhD or equivale degree and have research expe ience. The successful candida will participate in teaching fi year undergraduate courses biochemistry and genetics and t ability to teach some aspect genetics at a more advanced lev would be an advantage. Excelle facilities exist for research in variety of fields.

Salary will be at an appropri point on the Grade 1 (bar) sc £9,816 - £12,381 per annu according to qualifications a experience.

Further details may be obtain from Professor R H Pain, Depa ment of Biochemistry and Ge etics, The University, Newcas upon Tyne, NE2 4HH (Tel: 0 222 7368) with whom applicatio (three copies), together with t names and addresses of thr referees, should be lodged as so as possible and not later than 3 October 1989. (1530)A

UNIVERSITY OF LONDON

Sir Edward Frankland Chair of Inorganic Chemistry

at

Imperial College of Science, Technology and Medicine

The Senate invites applications for the Sir Edward Frankland Chair of Inorganic Chemistry tenable in the Department of Chemistry at Imperial College, which is available from 1 January 1990.

The new Professor will be Head of the Inorganic Section and will be expected to promote and make major contributions to research in any field of Inorganic Chemistry.

Applications (ten copies) by 13 November 1989 to **Miss I.R. Gardiner, Personnel Officer, Imperial College, London SW7 2AZ** from whom further particulars should first be obtained. (1482)A

UNIVERSITY OF HEIDELBERG

A POST-DOCTORAL POSITION

in Molecular Immunology is available immediately to study the expression of T cell receptor and cytokine genes in cloned human T cells. Strong background in molecular biology required. The position is initially for two years but can be extended.

Applications, including C.V., list of publications and names of two referees, should be sent to: **Prof. Dieter Kabelitz, Institute of Immunology, University of Heidelberg, Im Neuenheimer Feld 305, D-6900 Heidelberg, FRG** (W6472)A

MOLECULAR BIOLOGY

ASSISTANT PROFESSOR positio is available in molecular biolog for the study of the construction o chimeric genes and their expres sion. A competitive salary will b offered.

Applicants should submit thei curriculum vitae and the name and addresses of two references to **Dr. Constantin Bona, Microbiolog Dept., Box 1124, The Mt. Sina School of Medicine, One Gustav Levy Place, N.Y., N.Y. 10029.**

(NW4114)A

Geneticist
Department of Biology
University of Pennsylvania

Applications are invited for a tenure track faculty position at the Assistant or Associate Professor level in the discipline of Genetics Candidates studying problems in genetics or using genetic approaches to study problems in cell and developmental biology are encouraged to apply

Candidates should have a Ph.D. with postdoctoral experience and demonstrated research accomplishments. The successful candidate is expected to develop a strong research program and participate in teaching at the undergraduate and graduate levels.

Interested persons should send curriculum vitae, representative reprints, a brief description of future research plans, and 3 letters of reference by November 30, 1989 to:

Genetics Search Committee, Department of Biology, University of Pennsylvania, Philadelphia, PA 19104–6018

The University of Pennsylvania is an Equal Opportunity/Affirmative Action Employer and strongly encourages applications from women and minority candidates. (NW4192)A

ALBERT EINSTEIN COLLEGE OF MEDICINE
DEPARTMENT OF MOLECULAR GENETICS

FACULTY POSITIONS
IN EUKARYOTIC MOLECULAR GENETICS

Applications and nominations are invited for positions at the Assistant Professor level. Individuals with qualifications for higher level positions will also be considered. Candidates with outstanding academic achievements who will develop vigorous research programs in non-mammalian, eukaryotic molecular genetics are sought. The Department is adding several faculty to an active group of researchers. The college provides an outstanding interactive environment and attracts excellent students. Students in the department are sponsored by integrated PhD and MDPhD programs of the Graduate Division of the College.

Candidates should send Curriculum Vitae, a research plan, and request three letters of recommendation be sent to **Dr. Raju Kucherlapati, Department of Molecular Genetics, Albert Einstein College of Medicine, 1300 Morris Park Avenue, Bronx, New York 10461.** AECOM is an Equal Opportunity/Affirmative Action Employer. (NW4166)A

UNIVERSITY OF LEICESTER
POSTDOCTORAL RESEARCH COUNCIL

Two postdoctoral Research Associate positions are available for (1) an immunologist and (2) a molecular biologist The successful applicants will join a research team investigating the genetic design and evaluation of novel vaccines against parasitic and bacterial diseases

1. Immunologist· The applicant should have a strong background in immunology and an interest in either basic vaccinology, mucosal immunity, or host restriction. The position offers the scope for active collaboration with researchers in Switzerland, Sweden and Italy, and opportunities to work in these participating laboratories will be encouraged
2. Molecular Biologist. The applicant should have a strong background in molecular genetics and an interest in the application of protein engineering techniques The position will entail active collaboration with a major pharmaceutical company.

The appointments will have a starting salary of up to £14,169 (position 1) and £12,381 (position 2) per annum, depending on qualifications and experience (RA 1A scale £10,458–£16,665 per annum). Further details may be obtained from Dr. T.R. Hirst (0533–523431)

Applications, including a full c v. and the names and addresses of three referees, should be sent to **Dr. T.R. Hirst, Department of Genetics, University of Leicester, Leicester LE1 7RH** by 1 October 1989. (1498)A

DEPARTMENT OF GEOPHYSICS
UNIVERSITY OF WESTERN ONTARIO

Applications are invited for a tenure-track position, subject to the availability of funds An applicant must have a Ph.D., preferably in Geophysics, with at least two years postdoctoral experience and experience with high pressure-high temperature experiments on a cubic press The successful applicant will be required to teach at the undergraduate and graduate level and to devote considerable time to research, principally into the physical properties of matter at pressures and temperatures relevant to processes in planetary interiors, but also to other areas of interest to the applicant and the department. Salary is subject to negotiation and will depend upon the applicant's experience and qualifications. The effective date of employment is preferably 1990 07 01 but is subject to negotiation Closing date for receipt of applications is 1989 11 01. Address further enquiries to: **Dr. A.E. Beck, Professor and Head, Department of Geophysics, The University of Western Ontario, London, Ontario, Canada N6A 5B7.**

Positions are subject to budget approval. In accordance with Canadian Immigration requirements, this ad is directed to Canadian Citizens and Permanent Residents of Canada. The University of Western Ontario is an Equal Opportunity Employer. (NW4197)A

ROYAL HOLLOWAY AND BEDFORD
NEW COLLEGE
University of London

SCHOOL OF LIFE SCIENCES

Postdoctoral Research Assistant

Applications are invited for the position of Postdoctoral Research Assistant to work with Drs C Rider and A D Stead on the role of the ubiquitin in plant senescence Ubiquitin is a small protein involved in the targetting of proteins for rapid degradation This project is funded for 3 years by the AFRC as part of the recent Plant Molecular Biology Programme.

Applicants should possess or be expecting shortly to gain a PhD in Biochemistry, Plant Physiology or related discipline.

The experimental programme will involve Western blotting using specific antisera and the application of oligonucleotide probes This new project will be conducted alongside both existing work on ubiquitinated proteins from other sources, and other plant molecular biology projects

Salary on the scale £12,108–£18,315 per annum, including London allowance

Informal enquiries may be made to the supervisors (0784 434455 ext 3548 or 0784 435551 ext 38)

Applications, including a full c v and the names and addresses of two referees, should be submitted to the **Personnel Officer, Royal Holloway and Bedford New College, Egham Hill, Egham, Surrey, TW20 0EX** not later than 15th September 1989 (1481)A

UNIVERSITY OF CALIFORNIA, SANTA CRUZ
BIOLOGY DEPARTMENT

The department is committed to a significant expansion of resources including two new research buildings to be occupied Fall 1989 and 1992-93, expanding graduate programs and further new faculty positions. Selected candidates will be expected to teach at the undergraduate and graduate level. Applications from women and ethnic minorities are strongly encouraged. Positions are effective Fall 1990.

If you are applying for more than one position, you may submit one application as long as you indicate which position(s) the application is for.

Assistant Professor in Molecular Cell Biology: Applicant will be expected to develop a vigorous externally funded research program that used molecular approaches to address fundamental problems in the regulation of cell function, growth, and development. Seeking a creative scientist without regard to specific area of interest, but applicants investigating retrovirology, cell communication, signal transduction and working on vertebrate systems are especially encouraged to apply. Ph.D. and at least two years postdoctoral experience required. *Closing Date: December 1, 1989.*

Assistant Professor in Plant Cell/Developmental/ Molecular Biology: Applicants should use molecular and biochemical tools to study fundamental problems in plant growth and development. The successful candidate will be expected to develop a vigorous research program. Ph.D. and at least two years of postdoctoral experience required. *Closing Date: December 1, 1989.*

Associate Professor in Marine Vertebrate Physiological Ecology: Prefer specialization in marine mammals. Applicant must be able to apply modern experimental techniques, develop a strong laboratory-based research program at the Long Marine Laboratory, teach marine mammal and seabird bioenergetics and related courses. Ph.D., demonstrated record of scholarly research and University-level teaching required. *Closing Date: October 1, 1989.*

Send applications to:

Chair, Search Committee for
Molecular Cell Biologist #173-890
or
Plant Cell/Developmental/Molecular Biologist #161-890
or
Marine Vertebrate Physiological Ecologist #188-890

UCSC is an Affirmative Action/Equal Opportunity Employer

(NW4054)A

CATALYTIC CHEMIST

The Unocal Science & Technology Division has an immediate opening for a Catalytic Chemist at the Fred L. Hartley Research Center in Brea, California (about 35 miles east of Los Angeles).

The selected candidate will be involved in the development of hydroprocessing catalysts suitable for company refiner use or licensed installations. A BS in Chemistry with advanced studies in catalytic chemistry or several years industrial experience in catalyst development formulation is required.

U.S. Citizenship or permanent U.S. residency is required. Qualified candidates should send a resume to:

John S. Mahar
Supervisor, Human Resources
UNOCAL CORPORATION
Science and Technology Division
P.O. Box 76, Dept. 89032
Brea, CA 92621

An Equal Opportunity Employer

(NW4201)A

UNOCAL 76

Tenure-Track Faculty Positions in Molecular Biology

Applications are invited for two positions of Assistant Professor (tenure track in the Faculty of Medicine, University of Manitoba). Successful candidates are expected to establish an outstanding independent research program in the area of molecular biology as part of an Oncology group studying malignant progression. The positions require only minimal departmental teaching responsibilities. Requirements include a Ph.D. in Biochemistry or a related field, or an M.D., with at least two years of Postdoctoral experience. Candidates with a strong research background in the structure and function of oncogenes, growth factors or gene regulation are preferred. Applicants must have obtained a significant publication record in peer-reviewed journals.

Appointment at the Associate Professor level (tenured) may be considered for applicants who have demonstrated distinction in research and grant support.

Applicants should send a curriculum vitae, three signficant reprints, an outline of research plans, and the names of three references to: **Dr. A.H. Greenberg, Manitoba Institute of Cell Biology. 100 Olivia Street, Winnipeg, Manitoba, Canada R3E 0V9.** Deadline for receipt of applications is October 31, 1989.

Both men and women are encouraged to apply. In accordance with Canadian Immigration requirements, priority will be given to Canadian citizens and permanent residents, although all are encouraged to apply.

Manitoba Institute of Cell Biology (NW4208)A

NATIONAL INSTITUTE ON AGING
NATIONAL INSTITUTES OF HEALTH
PUBLIC HEALTH SERVICE
DEPARTMENT OF HEALTH AND HUMAN SERVICES

NMR Spectroscopists

(2 Positions Available)

The Laboratory of Cellular and Molecular Biology at the Gerontology Research Center, National Institute on Aging, National Institutes of Health, PHS, DHHS is accepting applications for two available positions.

One position is for studies on the effect of aging on metabolic changes that occur during human exercise, as well as in vivo studies on animals using a Bruker Biospec 1.9 T/31 cm Spectrometer. The successful applicant for this position will bear primary responsibility for in vivo NMR operations in the laboratory, will collaborate on the ongoing programs, and will initiate other studies.

The second position is for collaborative studies on the mechanisms of RNA synthesis at the active site of RNA polymerase, being investigated using a Varian XL-200 NMR spectrometer, an IBM-200-D EPR spectrometer and a variety of other techniques.

Salary dependent on qualifications.

Other NMR instruments in the area are available for use in these studies.

A letter of application with a curriculum vitae and bibliography should be submitted to:

Dr. Gunther L. Eichhorn
Chief, Laboratory of Cellular and Molecular Biology
National Institute on Aging, Intramural Research Program
4940 Eastern Avenue
Baltimore, Maryland 21224

Further information can be obtained by contacting Dr. Eichhorn at (301) 550-1807.

NIH IS AN EQUAL OPPORTUNITY EMPLOYER

(NW4116)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

TWO DEPARTMENTAL TECHNICIANS — GRADE 5

(Department of Physiology)

Required primarily (1) to assist Professor Widdicombe in research on the physiology of the respiratory tract and mucus secretion, and (2) to assist Drs Andrews and Williams on the physiology of vomiting and the neurophysiology of locomotion. Experience in a physiology laboratory would be an advantage. Appointment at a lower grade would be considered for qualified candidates without sufficient experience. Salary up to £11,322 per annum including London allowance, depending on experience and qualifications.

Further particulars and an application form from the **Personnel Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE.** 01-672-9944 ext 56020. Closing date 21 September 1989. Quote reference 125/89. (1513)A

THE MEDICAL COLLEGE OF ST. BARTHOLOMEW'S HOSPITAL
UNIVERSITY OF LONDON
Department of Biochemistry

SERC POSTDOCTORAL APPOINTMENTS IN PROTEIN ENGINEERING AND MECHANISTIC ENZYMOLOGY

Both positions are for work on fundamental aspects of enzyme mechanism and molecular recognition using the cysteine proteinase family of enzymes and mutants produced by site-directed mutagenesis.

Applicants for Post 1 (for 3 years from 1st October 1989 at a salary of £12,738-£14,031 p.a. inclusive of London Weightin) should have experience or interest in molecular biology and those for Post 2 (for 6 months from 1st October at £14,031 p.a. inclusive) interest in structure-reactivity relationships. The work planned for Post 2 is at an advanced stage and will lead to early publication.

Application with CV and the names of two referees to **Professor K. Brocklehurst** or **Dr I. Phillips, Department of Biochemistry, St. Bartholomew's Hospital Medical College, University of London, Charterhouse Square, London, EC1M 6BQ,** as soon as possible. (1516)A

MEDIZINISCHE EINRICHTUNGEN DER HEINRICH-HEINE-UNIVERSITÄT DÜSSELDORF

An der **Heinrich-Heine-Universität** ist die Stelle eines/einer Universitatsprofessors/Universitatsprofessorin **(Bes. Gr. C3 auf Lebenszeit)** fur Molekulare Wirkstoff-Forschung im Rahmen des geplanten Biologisch-Medizinischen Forschungszentrums zu besetzen.

Aufgabe ist die selbstandige Leitung einer Forschungsgruppe und Beteiligung an Lehrveranstaltungen im Rahmen eines Postgraduierten-Programms.

Der Schwerpunkt der Forschungstatigkeit sollte in der Bestimmung und Bewertung sowohl chemischer (Molekularparameterisierung) als auch biologischer Wirkstoffeigenschaften (Organ und Rezeptorebene) liegen. Der Bewerber sollte umfassende Kenntnisse und Erfahrungen in der Struktur-Wirkungsanalyse und möglichst auch Grundkenntnisse in COMPUTER ASS MOLECULAR DESIGN besitzen

Der Bewerber sollte nationale und internationale Kooperationen-sowie seine Fahigkeiten zur erfolgreichen Drittmitteleinwerburg nachweisen.

Einstellungsvorassetzungen sind die Habilitation oder vergleichbare Qualifikationen.
Bewerbungen Schwerbehinderter sind erwunscht.
Bewerbungen mit Lebenslauf, Darstellung des wissenschaftlichen Werdegangs und Schriftenverzeichnis werden erbeten bis 8 Wochen nach Erscheinen der Ausschreibung.

Der Rektor der Heinrich-Heine-Universität Düsseldorf, Universitätsstr. 1, 4000 Düsseldorf 1.

(W6456)A

UNIVERSITY OF ARIZONA
Department of Geosciences

DESERT GEOSCIENTIST

The Department of Geosciences at The University of Arizona invites applications for a tenure-track faculty position for an individual who is studying the Quaternary environmental history of deserts, geologic and biologic processes of deserts, or sedimentary deposits of arid lands. Candidates should expect to participate in all aspects of undergraduate and graduate teaching, to develop an active research program, and to play an active role in developing the University of Arizona program in Global Change in arid regions. Starting August, 1990, academic rank and salary will depend upon experience and qualifications. Send a curriculum vitae, bibliography, statements of research and teaching interests, and names and addresses of four professional references to: **Willian R. Dickinson, Chairman, Department of Geosciences, The University of Arizona, Tucson, Arizona 85721.** Deadline November 1, 1989. EOE/AA. (NW4177)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)

2 POSTDOCTORAL SENIOR RESEARCH OFFICERS (BIOCHEMICAL PHARMACOLOGY)

Applications are sought from postdoctoral scientists for 2 Senior Research Officers positions. Funding is on a Programme Grant from the Wellcome Trust, and 3 years are available for each position in the first instance. The research is directed to an examination of the biological activity of G-proteins in signal transduction, and experience in biochemistry, biochemical pharmacology, cell culture etc. would be an advantage. Informal enquiries are welcomed and should be made to Dr J. MacDermot (01-740 3219), Department of Clinical Pharmacology.

Salary on the 1A scale for Senior Research Officers (£10,458–£16,665 plus £1,650 London Allowance).

Application forms and further particulars are available from the **Personnel Office, Royal Postgraduate Medical School, Du Cane Road, London W12 0NN** (tel: 01-740 3204) quoting ref: AEW2.

Closing Date: 21 September 1989. (1490)A

UNIVERSITY OF Miami
SCHOOL OF MEDICINE

CHAIRMAN BIOCHEMISTRY AND MOLECULAR BIOLOGY

The University of Miami School of Medicine is seeking applications and nominations for the position of **Professor and Chairman of the Department of Biochemistry and Molecular Biology**. The person filling this position will have the unique opportunity to greatly expand the department's capabilities in the area of **Molecular Biology**. Substantial funds for the development of the department are available through a generous award from the Lucille P. Markey Charitable Trust as well as considerable funding from the University. In addition to funding the new chairman, these resources will be used to support at least ten new investigators, as well as start up funds and major new equipment. The department will occupy a new seven storey building which will be completed in the Fall of 1990. The department includes 16 faculty members (tenure track) with full time primary appointments and a well established graduate program with 35 trainees.

The applicant must have a Ph.D., M.D. or equivalent degree, be internationally recognized for contributions to molecular biological research, have a commitment to educational activities, and have clearly demonstrated leadership and administrative capabilities. The successful candidate is expected to be an outstanding scientist with a strong ongoing, independent and well-funded research program. This person will be expected to promote the molecular biological research capabilities of the department, the Medical School and the University, and to recruit outstanding scientists to the faculty.

Interested applicants should submit a curriculum vitae including the names of 3 references to. **Dr. James D. Potter, Search Committee Chairman, Department of Pharmacology, University of Miami, P.O. Box 016189, Miami, FL 33101.** *An Equal Opportunity/ Affirmative Action Employer.* (NW4186)A

UNIVERSITY OF LEICESTER
DEPARTMENT OF MICROBIOLOGY

RESEARCH ASSOCIATE/ASSISTANT

Applications are invited for a 3-year MRC-funded post available from October 1989 to investigate the role of *Bacteroides gingivalis* capsule in attachment and resistance to host defence mechanism. The project will involve exploiting the techniques of molecular and cellular biology to dissect out the role of the capsule in *B. gingivalis* infections. Experience in some aspect of molecular biology is desirable but not essential. This award is joint with Dr I S Roberts (University of Leicester) and Dr H Shah (London Dental Hospital).

Salary either in the IB range (£9,816-£12,381) or IA range (£10,458-£16,665) a year. It is unlikely that the initial salary will exceed £11,736 a year Applications including the names of two referees to: **Dr I S Roberts, Department of Microbiology, University of Leicester, LE1 9HN.** Tel: 0533-522956, from whom further details can be obtained. (1519)A

Research Associate

40 HR 8 AM–5 PM M–F. PH.D Organic or Medicinal Chemistry with at least 2 Yrs of Post Doctoral Exp. in Organic synthesis & strong background in High Field NMR & Mass. Exp. on large scale synthesis and chemistry of biologically active Natural Products. Advanced Research in synthetic organic chemistry involving novel nitrogen heterocycles of medicinal interest with special emphasis on N-[pyridyl(Phenyl) carbonylamino]-Alkyl 1, 2, 3, 6-tetrahydro pyridines. Conduct Laboratory scale organic reactions for the synthesis of target compounds & process development for large scale synthesis. Purification techniques involves various column chromatography techniques, thin layer, radial and HPLC. Applications of high field proton & carbon-13 NMR, Mass Spectroscopy, I.R, ORD & C.D. for structure elucidation. $24,000 year. Resume to **Job Service of Florida, 1307 North Monroe ST. Tallahassee, FL 32303. JO # FL–0148518.** (NW4195)A

UNIVERSITY OF Miami
SCHOOL OF MEDICINE

FACULTY POSITION MOLECULAR CELL BIOLOGY/ PHARMACOLOGY

The Department of Pharmacology at the University of Miami School of Medicine is seeking applications for a tenure-track faculty position. The position will be available in 1990; rank and salary will be commensurate with experience. Candidates for assistant or new associate professor are preferred. Generous lab space and start-up funds are available. Candidates must have a Ph.D. and/or M.D. degree (or equivalent), and should have an established record of research excellence in the broad area of molecular biological approaches to problems of pharmacological interest. The successful applicant will complement existing research efforts in the Department, which include regulation of cardiac and skeletal muscle function, transmembrane signalling mechanisms, function and development of the nervous system, and the regulation of gene expression.

Applicants should send a curriculum vitae, statement of past and future research interests, and the names and addresses of three references to **Dr. John L. Bixby, Search Committee Chairman, Department of Pharmacology, University of Miami, P.O. Box 016189, Miami, FL 33101.** *An Equal Opportunity/Affirmative Action Employer.*
(NW4187)A

POSTDOCTORAL RESEARCH ASSOCIATE IN MOLECULAR BIOLOGY/PATHOLOGY

Position opened for a postdoctoral candidate experienced in molecular biology to carry out in situ hybridizations for mRNA expressions of metastatic and anti-metastatic genes. This is a joint project of the Departments of Biochemistry, Pathology, and Urology of the Loyola University School of Medicine which seeks to determine in situ gene expressions that correlate with the metastatic phenotype. Salary competitive. Send curriculum vitae and names of three references to: **Dr. Chester Herman, Chairman, Department of Pathology, Loyola University Stritch School of Medicine, Maywood, IL 60153.**

Loyola University of Chicago is an Equal Opportunity/Affirmative Action Employer.
(NW4194)A

ASSISTANT PROFESSOR

The Department of Biological Chemistry and Molecular Pharmacology, Harvard Medical School, intends to make an appointment at the assistant professor level to begin in the fall of 1990. We are actively seeking applicants with strong research backgrounds in molecular biology, biochemistry, and molecular pharmacology, including membrane biology, structural biology, and gene regulation.

Applicants are invited to send curriculum vitae, bibliography, statement of research plans, and list of three to four referees to: **Professor Christopher T. Walsh, Chairman, Biological Chemistry and Molecular Pharmacology, Search Committee, Harvard Medical School, 240 Longwood Avenue, Boston, MA 02115.**

Women and minorities are encouraged to apply. Harvard University is an Equal Opportunity Employer.
(NW4191)A

UNIVERSITY OF Miami
SCHOOL OF MEDICINE

FACULTY POSITION MUSCLE RESEARCH

Research Assistant Professor position available in a well established and funded muscle research group. The laboratory is actively involved in studying the Ca^{2+} regulation of cardiac and skeletal muscle contraction by troponin using modern biochemical, biophysical and molecular biological approaches. Applicants should have a Ph.D. or equivalent degree and have experience in either biochemistry, biophysics or molecular biology.

Please send detailed curriculum vitae and names of three references to: **Dr. James D. Potter, Professor and Chairman, Department of Pharmacology, University of Miami, P.O. Box 016189, Miami, FL 33101.** *An Equal Opportunity/ Affirmative Action Employer.*
(NW4185)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)

POSTDOCTORAL RESEARCH FELLOW DEPARTMENT OF VIROLOGY

An enthusiastic postdoctoral scientist is required to join a well established team actively involved in research on cytomegalovirus. The group recently discovered that cytomegalovirus is immunologically protected in urine samples and the aim of the current project is to devise methods which can quantitate viruria without inhibition from this host protein. The methods to be used will include cell culture, immunofluorescence immunoblot, dot blot and the polymerase chain reaction. The post would be suitable for someone who has just obtained a Ph.D. and wishes to broaden their experience or for a research assistant fully experienced in one or more of the techniques to be used. Salary will be on Research Scale 1A. Further information about this three year post can be obtained from **Dr. Emery (01-794-0500, extn 3109)** or **Professor Griffiths (extn 3210).** A full job description can be obtained from the **School Office (extn 4262)** to whom applications **(four copies** of curriculum vitae including names and addresses of two referees) should be sent by **21 September 1989,** quoting ref. **V/R/33.**
(1505)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)
DEPARTMENT OF MEDICINE

GRADUATE RESEARCH ASSISTANT

required to work in an established neurotransmitter/hormonal peptide research laboratory. The work will involve the measurement of brain and gut regulatory peptides, including CGRP, and the investigation of their physiological and biochemical relationship to human disease. Preference will be given to candidates who are expecting to obtain a good honours degree in a relevant discipline such as biochemistry or physiology. The possibility of studying for a higher degree does exist.

Salary in the range £8,397-£9,178 p.a.

Please send full CV with name of two referees to the **Personnel Office, Royal Postgraduate Medical School, Ducane Road, London W12 0NN** quoting reference AMN3.

Closing Date: 21.9.89.
(1477)A

CHEMISTRY X-RAY CRYSTALLOGRAPHY MANAGER
Department of Chemistry, University of Toledo

Opening in Fall 1989 for Ph.D. scientist to manage X-ray crystallography activities. X-ray laboratory part of major new instrumentation center (anticipated completion 1990). Ph.D. in crystallography or related science with crystallographic postdoctoral experience preferred. Duties include: (1) management of two CAD4 single crystal diffractometers (currently installed), one powder diffractometer (to be purchased) and a VAX based computer network, (2) training of graduate students in crystallographic techniques, (3) collaborative research with faculty. This is a senior staff appointment in a rapidly developing department. Salary, mid-thirties with generous fringe benefits. Resume and three letters of recommendation to **J. E. Gano, Department of Chemistry, University of Toledo, Toledo, OH 43606.** *The University of Toledo is an EEO/AA employer.* TEL. (419)537-2104.

UNIVERSITY OF DUBLIN

TRINITY COLLEGE

Temporary Lecturer in Biochemistry

Applications are invited for the above post in the Department of Biochemistry at Trinity College, Dublin, commencing immediately. The post will be tenable for one year initially, and may be renewed for a second year.

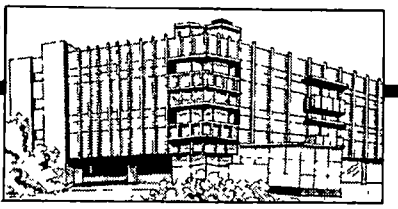
Candidates with expertise in any area of biochemistry and eukaryotic molecular biology will be considered.

Salary Scale: IR£11,239–IR£24,861 p.a.

Appointment will be made within the salary range IR£11,239 – IR£14,579 p.a. at a point to accord with qualifications and experience to date.

Application forms and further particulars relating to this post may be obtained from: **Establishment Officer, Staff Office, Trinity College, Dublin 2.**

to whom completed applications should be returned by *not later than 21st September, 1989.*



(1497)A

POSTDOCTORAL RESEARCH FELLOW

HARVARD SCHOOL OF PUBLIC HEALTH

Position available for postdoctoral fellow with training in molecular biology to study mechanisms of drug resistance in multidrug resistant mutants of the human parasite, *E. histolytica.* Send curriculum vitae, bibliography and three references to **Dr. John Samuelson, Department of Tropical Public Health, Harvard School of Public Health, 665 Huntington Avenue, Boston, MA 02115.** Women and minority candidates are encouraged to apply. (NW4158)A

RESEARCH TECHNICIAN II needed for DNA research experiments. Require M.S. Degree in Organic Chemistry, two years training in organic chemisry laboratory experience; ability to engage in DNA research by electrophoresis, DNA sequencing purification of DNA, HPLC and a variety of chromatography techniques to separate amino acids and nucleotides; ability to use radioisotopes; and background and skill in programming and data analysis by computer in Fortran language. Salary $9.62 per hour. Job Order No. 3920145. Contact **Utah Job Service, 1234 South Main Street, P.O. Box 11750, Salt Lake City, Utah 84147.** (NW4198)A

MERRELL DOW RESEARCH INSTITUTE
STRASBOURG CENTER

Invites applications for the position of

Biophysical Chemist

The Strasbourg Center is devoted to fundamental research directed towards rational design of new therapeutic agents,
The ideal candidate would have a Ph.D. in Biophysical Chemistry or related field and at least 2 years postdoctoral or industrial experience. The candidate must be familiar with the application of fluorescence and/or FTIR-ATR spectroscopic techniques to biological molecules and systems.
Merrell Dow Research Institute has a state-of-the-art biophysical laboratory with fluorescence, CD, FTIR-ATR and 500 MHz NMR instrumentation. The candidate would be expected to develop his own research interests as well as act as a resource for others in the institute.
In addition to the excellent resources and stimulating research environment, the position offers an attractive salary and benefit package.
Please send CV + 3 names of referees to:
Human Resources Department, Merrell Dow Research Institute,
16 rue d'Ankara, BP 447 R9, 67009 STRASBOURG Cedex.

(W6460)A

MEDIA-SYSTEM

POSTDOCTORAL POSITION to investigate the molecular mechanism of insulin action. Available early 1990. Salary negotiable. Send CV and 3 letters of recommendation to: **John C. Lawrence, Department of Pharmacology, Washington University School of Medicine, 660 South Euclid, St. Louis, MO 63110.** *The University is an equal opportunities employer.*

(NW4193)A

UNIVERSITY COLLEGE OF SWANSEA

LECTURER IN MARINE BIOLOGY

Applications are invited for the vacancy of Lecturer Grade A in Marine Biology in the School of Biological Sciences. The School is a large, well equipped and progressive department which offers a suitable candidate with a good research record, the opportunity to develop an active laboratory and to teach at all levels. The successful applicant will be required to teach courses in marine biology and with research interests which relate to the genetics and/or reproductive biology of aquatic animals. The appointment will date from November 1, 1989, or as soon as possible thereafter, and will be made in the middle range of the scale: £10,458 - £15,372 per annum together with USS benefits, if required. Informal enquiries may be made to Professor J A Beardmore, School of Biological Sciences (Tel: 0792 295382: Fax 0792 295447) but further particulars and application forms (2 copies) must be obtained from the Personnel Office, University College of Swansea, Singleton Park, Swansea, SA2 8PP, to which office they should be returned by **Friday, September 29, 1989.** (1488)A

UNIVERSITY OF OTAGO
Dunedin, New Zealand

MEDICAL PHYSICIST

Applications are invited from physicists with an excellent record of research and hospital experience in medical physics for appointment to a joint University-Otago Area Health Board post as Lecturer in Medical Physics and Medical Physicist in the Dunedin Hospital.

The Department of Physics at the University of Otago offers a two-year MSc programme in Medical Physics. This course, the only one of its type in New Zealand, consists of four papers and a research thesis, and presently caters for approximately ten domestic and foreign students at a time. The successful applicant will be responsible to the Chairman of the Department of Physics for directing the course and providing academic leadership in teaching and research in medical physics. This research will be expected to be allied to, and draw support from, one of the Department's areas of current expertise (laser physics and applications, optics, remote sensing by waves). A principal area of teaching will be in the two professional papers, 36 lectures each, offered in alternate years. The lecturer will be required to coordinate the supervision of research student projects which are distributed approximately 50% within the Department, and 50% in the Dunedin Hospital, the Medical School and the Dental School.

The initial appointment is for three years. At the end of two years this position will be reviewed. Intending applicants should contact Professor R. L. Dowden, Beverly Professor and Chairman of the Department of Physics for further information including details of the Department's current research, of the Medical Physics course, and of the Hospital Physics Department, by any one of these fast channels.

DIRECTORSHIP

INSTITUTE OF MARINE RESOURCES
UNIVERSITY OF CALIFORNIA

The University of California is seeking an outstanding scientist and scholar to direct the Institute of Marine Resources, a Universitywide Research Unit responsible for providing liaison between marine activities on UC campuses, fostering multi-campus and/or cross-disciplinary research programs, (e.g. global climate change) general administration of the California Sea Grant College Program, and serving as a main communication link about UC marine-related activities with the UC President's Office and external agencies.

The Directorship in the past has been located at the Scripps Institution of Oceanography at UC San Diego, but may reside at any other UC campus that has a major marine research program. The appointment is at the tenured full-professor level and would include an academic appointment in a relevant department.

The Director is expected to maintain an active research program and engage in activities of the department of which he or she is a member. Nominations and applications are invited from scientists with outstanding research records and demonstrated administrative skills in marine sciences, ocean engineering, or marine affairs and should be sent to:

Professor William Doyle,
Chair, IMR Search Committee,
Institute of Marine Sciences,
University of California,
Santa Cruz,
CA 95064.

Applications must include curriculum vitae, statement of research and interest in the position, and names of four referees. The position is open until filled. The committee will begin considering applications November 15, 1989.

The University of California is an Affirmative Action/Equal Opportunity Employer. (NW4176)A

POSTDOCTORAL RESEARCH POSITION

A postdoctoral research position is currently available in the field of molecular biology with application to studying gene regulatory aspects of xenobiotic metabolism in mammalian systems. The applicant will be involved in studying the regulation of cytochrome P-450 gene expression at the level of mRNA and protein synthesis/degradation in the lung and liver.

Send curriculum vitae and three letters of reference to: **Dr. Robert A. Blouin, College of Pharmacy, University of Kentucky, Lexington, KY 40536–0082.** (NW4164)A

Postdoctoral position

for two years, starting October 89 or later, in a research program including the pteridine metabolism in immune cells and the participation of pteridines in the control of lymphokine signal perception. The grant is DM 29.100,— per year and is sponsored by the Commission of the European Communities, Joint Research Program. Applicant with qualified background in and experience in enzymology and molecular cell biology must hold citizenship in a country of the European Community (except Germany). Address correspondence to **Dr. I. Ziegler, GSF-INSTITUT FÜR EXP. HÄMATOLOGIE, MARCHIONISTR. 25, D-8000 MÜNCHEN 70.** (W6478)A

IGNEOUS PETROLOGIST

Dartmouth College

The Department of Earth Sciences seeks to fill a tenure-track position in igneous petrology, at the Assistant Professor level, beginning with the 1990/1991 academic year. The successful candidate will be expected to develop a strong research and teaching program in igneous petrology. The Earth Sciences Department has a VG Sector Mass Spectrometer and a clean laboratory for Rb/Sr, Sm/Nd, and U/Pb analyses, and candidates with expertise in radiogenic isotope geochemistry are particularly encouraged to apply.

Please send inquiries with résumé, statement of teaching and research interests, and the names and addresses of three references to: **C. Page Chamberlain; Chair, Faculty Search Committee; Department of Earth Sciences; Dartmouth College; Hanover, N.H. 03755.** Applications should be received by October 15, 1989.

Dartmouth College is an affirmative action/equal opportunity employer. (NW4136)A

THE UNIVERSITY OF MICHIGAN CHAIR OF BIOLOGICAL CHEMISTRY

The University of Michigan Medical School is seeking an academic leader to direct the research, teaching, and service programs of its Department of Biological Chemistry. Qualifications include: A PhD (or M.D.) degree in Biological Chemistry or a related field, national stature as a researcher in an area of Biological Chemistry, commitment to teaching, and administrative ability. The position includes an instructional (tenure) track faculty appointment. **Please respond by October 15, 1989 to: Frederick C. Neidhardt, Ph.D., Chair, Biological Chemistry Review and Search Committee, c/o Ms. Susan E. Blackwell, Medical Administration Staff Assistant, The University of Michigan Medical School, M7325A Medical Science I Building, Ann Arbor, Michigan 48109-0624.**

The University of Michigan is a Non-Discriminatory Affirmative Action Employer. (NW4148)A

PARASITOLOGIST

CORNELL UNIVERSITY

New York State College of Veterinary Medicine. Assistant Professor of Parasitology, tenure track. The successful applicant will be expected to develop an independent, competitively funded research program focusing on host parasite interactions. Applicants should have a PhD or a DVM/PhD or equivalent. Experience in molecular biology and training at the postdoctoral level is required. This position is part of a major commitment by the department to apply molecular approaches to infectious disease research. Participation in the teaching of Parasitology to veterinary and graduate students will be required. Applications including a curriculum vitae, statement of research interests and the names and addresses of three referees should be sent to **Dr. Roger J. Avery, Chairman; Department of Microbiology, Immunology and Parasitology; New York State College of Veterinary Medicine, 616 Veterinary Research Tower; Cornell University; Ithaca, NY** 14853-6401 by November 15, 1989. Telephone inquiries will be welcomed (607-253-3400).

Cornell University is an equal opportunity/affirmative action employer/educator. (NW4189)A

UNIVERSITY OF OXFORD

DEPARTMENT OF PLANT SCIENCES

RESEARCH IN YEAST MOLECULAR GENETICS

Two Post-doctoral positions are available to work with Dr. B.S. Cox for three years.

Project 1: Controls of Genetic Recombination in Yeast.

Project 2: Fidelity of Translation.

Oxford has a number of groups working in the area of yeast molecular biology and genetics. Active contact between the groups is encouraged by all of them and frequent meetings are held.

Applications and enquiries for more information should be addressed to: Dr. Cox, Department of Plant Sciences, South Parks Road, Oxford OX1 3RA.

Closing date for applications: 2 October 1989.

The University is an equal opportunities employer. (1523)A

UNIVERSITY OF BATH
BIOCHEMISTRY DEPARTMENT

POSTDOCTORAL RESEARCH OFFICER
TRYPANOSOMES

Applications are invited for the post of Postdoctoral Research Officer to work with Dr M J Danson and Dr W Hough on a three-year project funded by the Wellcome Trust. The project concerns the enzyme lipoamide dehydrogenase of *Trypanosoma brucei*, the causative agent of African Sleeping Sickness. We have found the enzyme to be located at the plasma membrane and the project will involve its molecular characterisation at the protein and gene levels. The results of this project may lead to the design of novel chemotherapeutic agents.

Experience with molecular-biological or biochemical techniques is desirable.

Starting salary up to £11,070 p.a.

For further details telephone Dr Danson (Bath 826509) or Dr Hough (Bath 826867).

Application forms may be obtained from the **Personnel Office, University of Bath, Claverton Down, Bath BA2 7AY** or phone Bath (0225) 826095 quoting reference no: 89/229. Closing date: 22.9.89. (1506)A

UNIVERSITY OF EDINBURGH
POSTDOCTORAL ELECTROPHYSIOLOGIST

Applications are invited for the position of postdoctoral research fellow to study stretch-activated ion channels in plant cell membranes. The project will involve new patch clamp studies of channel activity in plants to determine how ion transplant is modulated by cell turgor pressure. Candidates should have an interest in ion transport in biological systems, but previous experience with plant cells is not required.

The post is available on the RA1A scale for three years and is funded by the AFRC as part of a collaborative project with Dr K. J. Oparka (Scottish Crop Research Institute). The person appointed will join a well-equipped group working on cell membranes and ion transport in plants.

Informal enquiries and applications including a curriculum vitae and the names of two referees should be addressed as soon as possible to **Dr J. A. C. Smith, Department of Botany, University of Edinburgh, The King's Buildings, Mayfield Road, Edinburgh EH9 3JH, U.K.** (tel. 031-667 1081 ext. 3319).

Please quote reference no. 5703. (1525)A

UNIVERSITY OF ABERDEEN
LECTURESHIPS IN CHEMISTRY

Applications are invited for two Lectureships in the Department of Chemistry. One of the successful candidates will be expected to contribute to the teaching of a course in Environmental Science and to have his/her main research interest in envrionmental chemistry without restriction of specific area. This appointment will be for five years initially, with the possibility of renewal. The second position is for a candidate whose research interests lie in the synthesis and/or properties of new organic and/or inorganic materials. Initial salary will be on the Lecturer salary scale £10,458 - £20,469 per annum with appropriate placing.

Further particulars and application forms from the Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX to whom applications (2 copies) should be returned by 7 October 1989 quoting reference number JA/059. (1502)A

UNIVERSITY OF LEICESTER
DEPARTMENT OF BIOCHEMISTRY

POST-DOCTORAL RESEARCH ASSOCIATE

Applications are invited for a post-doctoral position funded by the Cancer Research Campaign, to work on the organisation and expression of the retinoblastoma-susceptibility gene (RB-1) in human breast tumours. The successful applicant will join a group working on various aspects of human breast cancer housed within the Department of Biochemistry, but with very close links with the Department of Pathology. The project will involve analysis of changes to the RB-1 gene in breast tumours and examination of the RB-1 gene during normal development (Science, 242, 263; Oncogene, 4, 725). Research experience in techniques of molecular biology is required.

The appointment will be for three years on the University grade 1A scale (£10,485 to £16,665 per annum).

Applications, together with a curriculum vitae, and the names and addresses of two referees, should be sent to **Dr. J. M. Varley, Department of Biochemistry, University of Leicester, University Road, Leicester LE1 7RH,** to whom informal enquiries may be made (0533-523366). (1499)A

RESEARCH FELLOW
(MOLECULAR BIOLOGIST)

$A31,525 - $A38,567

DIVISION OF ANIMAL HEALTH, PARKVILLE, VICTORIA

THE DIVISION: The CSIRO Division of Animal Health has laboratories at Parkville, Geelong, Sydney and Armidale and undertakes research into diseases of Australian livestock

THE PROJECT: CSIRO is undertaking a large multi-divisional approach to the development of vaccine technologies The Division of Animal Health is conducting research into the potentiation of the host's immune response to vaccines. As part of this project we wish to examine the role of the cytokines in the control and regulation of the immune response to infection

THE JOB: To prepare cDNA libraries from sheep lymphocytes and somatic cells. To clone and express a variety of ovine cytokine genes using homologous DNA probes or by expression of mammalian cell systems. The appointee will have responsibility for supervision of junior staff and will be part of a team of six working on this project

THE PERSON: Applicants should have a doctorate or equivalent qualification in microbiology, genetics, immunology or an associated field Recombinant DNA experience is essential. Experience in the preparation and screening and cDNA libraries would be highly desirable

CONDITIONS: Appointment as a Research Scientist for 3 years from January 1990. Australian Government Superannuation benefits are available.

MORE INFORMATION: Prospective applicants are invited to call Dr Paul Wood on (03) 342 9783 for further information. A copy of the detailed duty statement and selection criteria can be obtained by calling the Personnel Officer, Mr Philip Platon on (03) 342 9700 or by fax (03) 347 4042.

APPLICATIONS: Applications should be submitted by 29 September 1989 and quote Reference No. PG 120/1/55 They should be framed against the selection criteria and should provide details of relevant personal particulars, including qualifications and experience Applicants should nominate at least two professional referees and address their application to.

The Chief,
CSIRO Division of Animal Health,
Private Bag No. 1,
Parkville, Victoria, 3052 (W6466)A

POSTDOCTORAL RESEARCH ASSOCIATE

To investigate the power and energy changes in fish muscle during contractions which simulate those during swimming. The work will be done in the laboratories of Dr N. A. Curtin (CXWMS) and Prof R. C. Woledge (UCL). This SERC funded post is for 3 years, starting on January 1st 1990. Previous experience in muscle physiology is an advantage but is not essential as training will be given.

Further information can be obtained from either Dr Curtin (01-846 7287) or Prof Woledge (01-380 7133). Applications including CV and names of two referees should be submitted to **Prof R. Woledge, Physiology Department, University College, Gower Street, London WC1E 6BT,** by October 15th.

Equal Opportunity Employer. (1478)A

PAKISTAN

Academic appointments for the Ghulam Ishaq Khan (G.I.K.) Institute of Engineering Sciences and Technology, Topi, North Western Frontier Province, Pakistan.

SOPREST (Society for the Promotion of Engineering Sciences & Technology in Pakistan) is a registered Society which is approved as a Charitable Institution by the Government of Pakistan.

Mr. Ghulam Ishaq Khan, President of the Islamic Republic of Pakistan, is one of the 12 Founding Members of the Society and also its President and Chief Executive Officer for life. Other Founding Members include eminent industrialists, scientists and engineers of the Country.

The objective of SOPREST is to establish centres of excellence in Pakistan in the *Private Sector* in the fields of modern engineering and technological education.

The G I.K Institute is the first centre of excellence proposed to be established by SOPREST in TOPI near the Scenic TARBELA DAM in the NWF Province of Pakistan. About 220 acres of land has already been donated by the N.W.F.P. Government for the Project site and detailed designing work is in progress

The Institute will, over a period, provide educational and research facilities to at least 400 students every year ranging from the undergraduate levels to Ph.D. in the following disciplines:

1. Metallurgy and Materials Science
2 Mechanical Engineering
3. Computer Science
4. Electronic Engineering
5 Applied Physics and Mathematics

Vacancies under each of these disciplines in the following cadres would need to be filled in the near future by well qualified, internationally reputed and experienced candidates.

— Rector of the Institute
— A Dean for each of the five faculties
— Professors, Assistant Professors and Research Associates

} Salary and terms negotiable

Please apply with full curriculum vitae to:
Mr. H. U. Beg
Executive Director, SOPREST,
4/A, Street No. 41, F-7/1,
Islamabad, PAKISTAN. (W6444)A

UNIVERSITY OF WALES COLLEGE OF MEDICINE
Department of Medical Microbiology
POSTDOCTORAL RESEARCH OFFICER

RESEARCH OFFICER required to work on the "Relationship between cell surface glycoproteins, TNF susceptibility and the metastatic potential of tumour cells". The post is funded by the Cancer Research Campaign and is available from October 1989 for one year in the first instance. The commencing salary will be up to £12,381 on the scales for University Research and Analogous Staff.

Informal enquiries may be made to Dr. N. Matthews (tel. 0222–755944 Ext. 3520).

Application forms and further particulars available from the **Registrar and Secretary (Personnel Office), University of Wales College of Medicine, Heath Park, Cardiff, CF4 4XN** to whom applications in the form of a curriculum vitae with the names and addresses of two referees should be submitted by the 29th September, 1989. (1533)A

THE UNIVERSITY OF WARWICK
DEPARTMENT OF BIOLOGICAL SCIENCES
POSTDOCTORAL RESEARCH FELLOW

A biochemist/microbiologist with experience in protein purification techniques is required as soon as possible for a project jointly supervised by Professor D. P. Kelly (Warwick) and Dr. R. Cammack (King's College London) The aim is to determine the structure and function of a novel manganese-protein and other enzymes in the thiosulphate-oxidizing system of *Thiobacillus versutus*. The Fellow will be based at Warwick, where organism cultivation, enzyme purification, kinetic and some chemical assays will be done. The Fellow will also work at King's College, where electron spin resonance spectroscopy studies will be carried out.

The appointment will be for up to three years on the Research IA scale: £10,458 to £16,665 p.a. Further particulars can be obtained by telephoning Professor Kelly on 0203-523181 (direct line). Application forms from the **Executive Officer, Department of Biological Sciences, University of Warwick, Coventry, CV4 7AL,** quoting Ref. No. SERC/DPK. Closing date: 15 September 1989.

AN EQUAL OPPORTUNITIES EMPLOYER (1511)A

DEPARTMENT OF BIOCHEMISTRY
University of Geneva
FACULTY OF SCIENCES

A full-time position has been opened for a scientist capable of directing a strong research program in biochemistry. All fields of research will be considered. The position will be filled at the rank of Full Professor, or possibly at a lesser rank for promising younger candidates.

Teaching at undergraduate and graduate levels will be required. The language of instruction is French, but a period of adjustment to this requirement can be granted

The proposed starting date is October 1990, but this is negotiable.

Applications should be sent by November 15, 1989 to: **Secrétariat de la Faculté des Sciences, Université de Genève, 20, quai Ernest-Ansermet, CH-1211 GENEVA 4, Switzerland,** from whom additional information can also be obtained.

DIRECTOR

CENTER FOR ENVIRONMENTAL AND ESTUARINE STUDIES
University of Maryland System

The University of Maryland seeks a director to serve as chief administrative officer for its Center for Environmental and Estuarine Studies (CEES), an institution of the University of Maryland System. The Center is charged with the responsibility to produce and to develop new knowledge through a program of research, education, and public service. Center headquarters are in Cambridge, Maryland, with three regional laboratories — Horn Point Environmental Laboratories located on the Eastern Shore coastal plain, Chesapeake Biological Laboratory on the Western Shore of the Chesapeake Bay, and the Appalachian Environmental Laboratory in the mountains of Western Maryland. Areas emphasized include fisheries science and aquaculture, environmental chemistry, and geochemistry, aquatic toxicology, systems ecology, estuarine and coastal oceanography, nutrient cycles, estuarine circulation, wetland ecology, freshwater and terrestrial ecology, wildlife biology, and environmental policy.

Scientists with a distinguished record of research and administration are invited to apply. The successful candidate will be expected to supply administrative and programmatic leadership to growing academic and research programs and will be qualified for the rank of full professor at CEES. At present, the Director adminsters a scientific and support staff of approximately two hundred and fifty, forty-five of whom are academic faculty; an operating and research budget of approximately $16 million; a research fleet and a large physical plant. In Fiscal Year 1989, CEES received approximately $7.7 million in sponsored research awards. The Director reports to the Chancellor of the University of Maryland System, and is administratively equivalent to a President in the University of Maryland System.

Nominations are invited. Applicants should include current resumes and details of present responsibilities.

Nominations and applications should be sent to:

Dr. David S. Sparks
Vice Chancellor for Academic Affairs
Chairman, Search Committee,
Director of CEES
University of Maryland System,
Adelphi, MD 20783

Those received by October 16, 1989, will receive first consideration. Those arriving after that date may be considered by the Committee if received before the final report is submitted. All applications and inquiries will be treated as confidential.

The University of Maryland System is an affirmative action, equal opportunity employer. (NW4162)A

DEPARTMENT OF BIOCHEMISTRY

TWO POSTDOCTORAL SENIOR RESEARCH ASSISTANTS

To join a group investigating the isoprenoid biochemistry of plants The research will (a) examine in detail the pathways of mevalonic acid formation in plant tissue cultures and whole plants and (b) purify and investigate the regulation of the key enzymes involved Tenable immediately and for two and three years Salary on the scale £10,458–£12,381 per annum

Informal enquiries to Dr. L J Goad (051-794 4343) or Dr R Powls (051-794 4352).

DEPARTMENT OF GENETICS AND MICROBIOLOGY

POSTDOCTORAL SENIOR RESEARCH ASSISTANT

To work on chromatin structure and activity in a group run jointly by Professor J. P. Baldwin at Liverpool Polytechnic and Dr R S. Hill at the University Applicants should have an interest in biological molecular structure and, ideally, a working knowledge of small angle scattering and/or x-ray crystallography. Informal enquiries to Professor Baldwin, School of Information Science and Technology, Liverpool Polytechnic, Byrom Street, Liverpool L3 3AF, (051-207 3581) or Dr Hill at the University address below (051-794 3628/3622)

The post is tenable for up to two years from 1st October 1989 at an initial salary of either £9,816 or £10,458 per annum

Quote ref RV/491/N

Applications for both the above posts, by c v. with the names of three referees, should be received as soon as possible, by The Director of Staffing Services (AS), The University, P O Box 147, Liverpool L69 3BX, from whom further particulars may be obtained.

University of LIVERPOOL (1538)A

An Equal Opportunity Employer

UNIVERSITY OF GLASGOW

Department of Veterinary Pathology

POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for a post-doctoral research assistant to join a group in the above department studying the molecular basis of pathogenicity in the bacterial respiratory pathogen *A. pleuropneumoniae.* The project will examine the role of extracellular cytotoxic products of this organism in swine pleuropneumonia. It will involve a variety of molecular biological techniques, the use of existing and the generation of additional Mab, EM, protein purification and bacterial gene cloning and expression.

The project is funded by the Wellcome Trust for three years. Candidates should possess or be completing a PhD but those with an appropriate first degree and relevant experience may also apply. Salary will be on the 1A scale (£10458-£16665) with superannuation under USS conditions.

Applications, including a full curriculum vitae and the names of three referees should be sent to **Dr. A. N. Rycroft, Dept. of Veterinary Pathology, University of Glasgow Veterinary School, Bearsden, Glasgow G61 1QH,** from whom further details may be obtained. (1521)A

IMMUNOLOGISTS

The University of Washington seeks highly-qualified applicants for tenure-track appointments in the newly formed Department of Immunology. Applicants must have a Ph.D. or M.D. degree, appropriate post-doctoral training, and must have demonstrated their ability to establish strong independent research programs in immunobiology. We invite applications from molecular and cellular immunologists, particularly those interested in applying molecular genetic techniques to the elucidation of mechanisms of antigen recognition, signal transduction, or lymphocyte development. The Department of Immunology offers superb new laboratory space with access to flow cytometry, biopolymer synthesis, and transgenic animal facilities. Send curriculum vitae, a brief description of proposed research, and three letters of recommendation (by December 1, 1989) to **R.M. Perlmutter, M.D. Ph.D., Chairman, Department of Immunology, SL-05, University of Washington, Seattle, WA 98195.**

The University of Washington is an Equal Employment/Affirmative Action Employer. (NW4207)A

FELLOWSHIPS

KING'S COLLEGE LONDON (PHYSIOLOGY) AND MRC CLINICAL RESEARCH CENTRE

POSTDOCTORAL FELLOWSHIP IN VASCULAR BIOLOGY

(BRITISH HEART FOUNDATION)

Applications are invited for a two year British Heart Foundation funded postdoctoral fellowship with Dr G.E. Mann (King's College) and Dr J.D. Pearson (Clinical Research Centre) to characterize regulation of L-arginine transport and its role in EDRF (nitric oxide) biosynthesis in perfused microcarrier cultures of coronary and aortic vascular endothelial cells (see Mann et al., J Physiol 410: 325–339, 1989). Nitric oxide is a potent regulator of vascular tone and inhibitor of platelet aggregation and adhesion. Our research aims to identify, and to pharmacologically modify, precursor pathways leading to the utilization of substrate for nitric oxide biosynthesis. An existing collaborative research link with Dr S. Moncada (Wellcome Research Laboratories) should enable us to correlate L-arginine transport with bioassay and chemiluminescence measurements of nitric oxide release.

Starting salary on the RA1A scale will be in the range of £12,108-14,031 (incl. London Allowance). Informal enquiries can be made to Dr G.E. Mann (01-937-5411 ext 450). Applications, including a full CV and names and addresses of two academic referees, should be sent by 1 October 1989 to **Dr G.E. Mann, Biomedical Sciences Division (Physiology), King's College London, Campden Hill Road, London W8 7AH.** (1540)E

U.S. Department of Energy

ALEXANDER HOLLAENDER DISTINGUISHED POSTDOCTORAL FELLOWSHIP PROGRAM

Hollaender Postdoctoral Fellowships provide research opportunities in the life, biomedical, and environmental sciences. Fellowships are tenable at various Department of Energy and university laboratories with programs supportive of the Office of Health and Environmental Research. Stipend is $35,000. A doctoral degree received after April 1, 1988, is required as is U.S. citizenship or PRA status. Deadline is January 16, 1990.

For applications contact: **Hollaender Postdoctoral Fellowships, Science/Engineering Education Division, Oak Ridge Associated Universities, P.O. Box 117, Oak Ridge, TN 37831-0117, (615) 576-3190.** (NW4167)E

UNIVERSITY OF READING

Department of Chemistry

COMPUTER MODELLING OF CATALYSTS

An SERC-funded POSTDOCTORAL RESEARCH FELLOWSHIP is immediately available for three years in collaboration with Dr. M. G. B. Drew and Dr. P. C. H. Mitchell. An interest in applying computer modelling to surface chemistry and catalysis is required. Applicants should have a relevant background in chemistry, physics or computer science. The post will provide experience of working in an area of rapidly developing academic and industrial importance. Salary up to £11,736 p.a. Apply for Application Form to **Personnel Officer, University of Reading, Whiteknights, P.O. Box 217, Reading RG6 2AH,** telephone (0734) 318754. Please quote Ref. R8953. (1518)E

CANADIAN INSTITUTE FOR THEORETICAL ASTROPHYSICS/INSTITUT CANADIEN D'ASTROPHYSIQUE THEORIQUE

RESEARCH FELLOWSHIPS

CITA is a national centre for theoretical astrophysics located at the University of Toronto. The Institute expects to offer five to ten research fellowships with a starting date of September 1, 1990. The appointments will be of two kinds: postdoctoral fellows (two years duration) and research associates (three years renewable to five). Funds will be available to each fellow for travel and other research expenses. Fellows are expected to carry out original research in theoretical astrophysics under the general supervision of the permanent faculty or visitors to CITA, whose interests include: cosmology, interstellar matter, nuclear and relativistic astrophysics, star formation, stellar structure, active galactic nuclei and galactic and solar system dynamics.

Applicants should send a curriculum vitae and statement of research interests and must arrange themselves for three letters of recommendation to be sent to: Professor S. Tremaine, Director, Canadian Institute for Theoretical Astrophysics, University of Toronto, 60 St. George Street, Toronto, Ontario Canada M5S 1A1.

Application Deadline is December 31, 1989. (NW4149)E

EMBO

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION

SHORT TERM FELLOWSHIPS

in molecular biology

The European Molecular Biology Organization awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of application.

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatlantic travel are awarded only in exceptional circumstances. Inquiries should be accompanied by a self-addressed adhesive label.

Application forms and further details may be obtained from **Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F.R.G.** (W5706)E

FRIEDRICH MIESCHER-INSTITUT

BASEL, SWITZERLAND

POSTDOCTORAL FELLOWSHIP

Applicants with a recent Ph.D are invited for an internally funded fellowship of up to 3 years maximum duration to join an established team working on the role of DNA methylation in eucaryotic gene regulation and on the interaction of tissue-specific transacting factors (*in vivo* and *in vitro*) with regulatory elements of genes.

The possible role of covalent modifications of transacting factors will also be studied. We are working on genes that control differentiation and genes controlled by hormones. The Institute provides outstanding facilities in a purely research environment.

Position is available in spring 1990. Candidates should have a good background in biochemistry, molecular biology and biology.

Applications (with CV) should be sent to: **Dr. Jean-Pierre Jost, Friedrich Miescher-Institut, P.O. Box 2543, CH 4002 Basel, Switzerland.** (W6465)E)

UNIVERSITY OF KENT

AT CANTERBURY

POST DOCTORAL RESEARCH FELLOWSHIP IN ENVIRONMENTAL MICROBIOLOGY

Applications are invited for a three year post-doctoral research fellowship in an environmental microbiology group led by Dr R G Burns. Salary on RA1A Scale (£10,458-£16,665).

The project involves the monitoring of bacteria introduced into soils and rhizospheres in both laboratory microcosms and field experiments. Conventional and recently developed immunological techniques (including strain specific monoclonal antibodies) will be used for the sensitive tracking of bacteria.

The project is sponsored by Shell Research and some of the studies will be in collaboration with scientists at nearby Sittingbourne.

Suitable applicants are likely to have a Ph.D in some aspect of environmental microbiology and experience in soil/plant root/microorganism interactions.

Further details can be obtained from Dr R G Burns (0227 764000 ext. 3698).

Application forms and further particulars are available from **Mr J E Reilly, Secretary of Faculties and Deputy Registrar, The Registry, University of Kent at Canterbury, Kent CT2 7NZ,** quoting reference A90/2. Closing date: 22nd September 1989.

An equal opportunities employer. (1515)E

UNIVERSITY OF OXFORD

MERTON COLLEGE

Junior Research Fellowships 1989

The College proposes, if candidates of sufficient merit present themselves, to elect in 1989 to two or three Junior Research Fellowships. These Fellowships are open to both men and women. Candidates must not have accumulated more than six years in post graduate study or research by 1 October 1990.

Details of the awards and of the method of applying for them may be obtained by writing to the Warden's Secretary, Merton College, Oxford, OX1 4JD. Closing date for applications is Friday 6 October 1989. (1491)E

The Hebrew University of Jerusalem

Jerusalem Israel

The Golda Meir Fellowship Fund

Postdoctoral Fellowships

The Hebrew University of Jerusalem invites applicants for Postdoctoral Fellowships in Humanities, Social Sciences, Natural and Applied Sciences, Agriculture and Medicine for the 1990/91 academic year.

Candidates may apply at an early stage of their professional career (not later than 3 years after completion of their doctoral dissertation).

The fellowships are tenable for one academic year and may be extended for another year.

The fellowship provides a 12-month stipend (with COL adjustments), rent allowance and a return ticket to Israel.

Application forms can be obtained from the **Office of University Funds, P.O. Box 1255, Jerusalem, 91904, Israel.**

Completed application forms must be returned by December 1, 1989. (W6462)E

HOWARD HUGHES MEDICAL INSTITUTE

POSTDOCTORAL RESEARCH FELLOWSHIPS FOR PHYSICIANS

1990 Competition

Fellowships are for full-time training in fundamental research on basic biological processes and disease mechanisms.

Fellowship Terms

3 years of support
$35,000-$50,000 stipend
$15,000 research allowance
$12,000 institutional allowance

Eligibility

M.D., M.D./Ph.D., D.O.
At the start of the fellowship
at least two years of clinical training and
no more than three years of research training
No citizenship requirements

Schedule

Application deadline: **March 1, 1990**
Awards announced: **October 1990**
Fellowships start: **January 1991 — July 1992**

For Program Announcements and Applications

Howard Hughes Medical Institute
Office of Grants and Special Programs
6701 Rockledge Drive
Bethesda, MD 20817
United States of America
Telephone (301) 571-0324

The Howard Hughes Medical Institute, an Equal Opportunity Employer, welcomes applications from all qualified candidates and encourages women and members of minority groups to apply.

(NW4151)E

HOWARD HUGHES MEDICAL INSTITUTE

DOCTORAL FELLOWSHIPS IN BIOLOGICAL SCIENCES

1990 Competition

Fellowships are for full-time study toward the Ph.D. or Sc.D. degree in cell biology and regulation, genetics, immunology, neuroscience, and structural biology.

Fellowship Terms

Three-year initial awards
Two-year extensions possible
$12,900 annual stipend, effective June 1990
$11,700 annual cost-of-education allowance, effective June 1990

Eligibility

Less than one year of postbaccalaureate graduate study in biology
College seniors
First year graduate students
M.D., D.O., D.D.S., D.V.M. students or professionals
If in M.D./Ph.D. program
Less than one year equivalent of tuition support
No citizenship requirements
U.S. citizens may study abroad
Others must study in the United States

Schedule

Application deadline: **November 9, 1989**
Awards announced: **Early April 1990**
Fellowships start: **June 1990 — January 1991**

NOTE: Fellowships are highly competitive. In 1989 more than 1,000 applications were reviewed to select 60 fellows.

THE UNIVERSITY OF AUCKLAND
NEW ZEALAND
POSTDOCTORAL FELLOWSHIPS

The following Postdoctoral Fellowships are available for a period of two years, commencing on a date to be arranged during the period 1 February to 1 October 1990.

Department of Zoology Reference A89/01
Professor P R Bergquist (FAX 64-9-799 317)
"Chemistry, Pharmacology & Molecular Evolution of the Porifera"
The project will focus, depending upon the applicant's skills, upon molecular biology where experience in DNA and RNA sequencing and computational approaches to sequence comparison will be sought *or* upon experience in marine natural products chemistry and bioassay techniques Familiarity with standard techniques for extraction, purification and characterisation of lipid and water soluble components is essential (ie NMR, HPLC, GC/MS). An interest in marine biology and scuba competence is also appropriate.

Department of Chemistry (Reference A89/03)
Professor R P Cooney (FAX 64-9-302 1795, Telex UNILIB NZ 21480)
"Molecular Analysis at the Metal/Solvent Interface"

Applicants should have experience in physical and inorganic Chemistry. The project will be concerned with the application of FT-IR, Laser Raman and XPS/Auger Spectroscopy to the study of molecular processes at metal/aqueous interfaces, including systems of strategic importance.

Department of Cellular & Molecular Biology Reference A89/04
Professor R K Ralph, Dr. W Judd (FAX 64-9-303 1618)
"Anti-malarial Agents Target as Topoisomerase"

Applicants should have experience so as to enable them to investigate the potential of a range of locally synthesized anti-cancer drugs directed against topoisomerase II or DNA as anti-malarial or anti-trypanosomal agents.

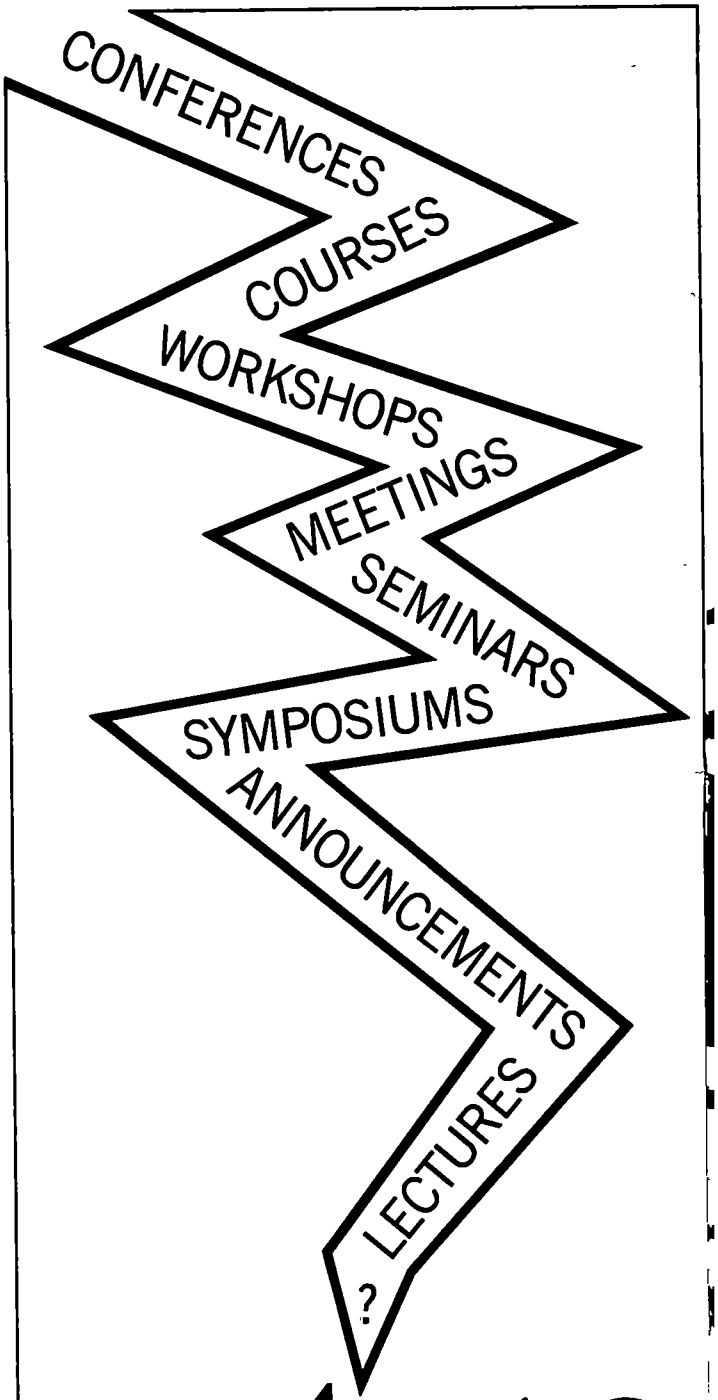
Department of Biochemistry (Reference A89/05)
Professor A G C Renwick (FAX 64-9-799 317)
"Determination of Disulphide Bonds in the α & β subunits of Mammalian Glycoprotein Hormones"

Applications are invited for a Postdoctoral Fellowship to work on glycoprotein structure using FAB/MS. If necessary, arrangements can be made for a suitably qualified person to gain experience in this technique before coming to New Zealand.

Department of Cellular & Molecular Biology Reference A89/06
Dr. R C Gardner (FAX 64-9-303 1618)
"Tissue-specific Gene Expression in Kiwifruit"

Applicants should have experience in basic recombinant DNA techniques.

Applicants must have completed the requirements for the award of a PhD. or its equivalent, within the last four years. A stipend of NZ$35,000 per annum, plus one return airfare will be paid. Applicants are invited to seek further information from the supervisor of each topic.



Application forms and Conditions of Appointment are available from the **Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF;** or from the **Assistant Registrar (Academic Appointments), University of Auckland, Private Bag, Auckland, New Zealand** (Telephone 737 757, FAX 64-9-799 317). Please quote reference number in all enquiries.

The closing dates are 9 October 1989, or as soon as possible thereafter.

The University of Auckland
An Equal Employment Opportunity Employer.
(W6470)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
JUNIOR RESEARCH FELLOWSHIP

Applications are invited from students with good, appropriate degrees for a 3 year Ph.D. studentship starting 1 October to study mechanisms of ageing in the nervous system. The student will learn to use a range of state-of-the-art neuroscience techniques, including immunohistochemistry, neuronal tracing techniques and image analysis. He or she will be part of a small, active research group in a friendly laboratory. Conditions are comparable to those offered by SERC and include a maintenance grant of £4,690 per annum. Enquiries and applications to **Dr Tim Cowen (01-794 0555, ext: 4356), Department of Anatomy, R.F.H.S.M., Rowland Hill Street, London NW3 2PF.** (1493)E

THE AUSTRALIAN NATIONAL UNIVERSITY

POSTDOCTORAL FELLOWSHIP

ACCELERATOR MASS SPECTROMETRY

Department of Nuclear Physics

Research School of Physical Sciences

Applications are invited for appointment to an Australian Research Council-funded Research Fellowship to participate in research and development of accelerator mass spectrometry (AMS).

In collaboration with ANSTO, the Department is engaged in a very active program of AMS, using the 14UD accelerator. Routine measurement procedures have been established for chlorine — 36 and other work has involved beryllium 10 and carbon — 14. It is proposed that the successful applicant will contribute towards further developments of AMS, particularly in new applications in environmental studies and the geo-sciences.

Previous experience with AMS is desirable, but not essential. However, applicants would be expected to have recently completed a PhD degree in an experimental research area providing experience in one or more of the following: accelerator operation, online data acquisition with a computer, heavy iron particle detectors and the use of analog and logic pulse electronics.

Enquiries may be made of Dr C.R. Ophel, Head of Department, Telephone (062) 49-2086.

Closing date: 15th October 989. Ref: PS 17.8.1.

SALARY: Fixed point in the range A$27,139 – $30,882 p a.

APPOINTMENT: Normally two years, possibility of extension to three years.

APPLICATIONS should be submitted in duplicate to the Registrar, The Australian National University, GPO Box 4, Canberra, ACT 2601, Australia, quoting reference number and including curriculum vitae, list of publications and names of at least three referees. The University reserves the right not to make an appointment or to appoint by invitation at any time. Further information is available from the Registrar, or from Appointments (6823), Association of Commonwealth Universitites, 36 Gordon Square, London WC1H 0PF.

THE UNIVERSITY IS AN EQUAL OPPORTUNITY EMPLOYER. (W6457)E

MASSEY UNIVERSITY Palmerston North, New Zealand

POSTDOCTORAL RESEARCH FELLOWSHIPS

Applications are invited for seven Postdoctoral Research Fellowships, four of which are funded by the University Grants Committee and three by the University.

UNIVERSITY GRANTS COMMITTEE POSTDOCTORAL FELLOWSHIPS

The Pathogenesis of Ceroid-lipofuscinosis

A position is available in the Department of Veterinary Pathology and Public Health under the leadership of Professor R D Jolly. The successful candidate should have a professional background in one or more of the following fields: Protein chemistry, Cell/Molecular biology, Immunocytochemistry and Electron Microscopy. The pathogenesis of the ceroid-lipofuscinoses is being studied in the ovine model but the work is extended to involve the analogous diseases of children These are inherited lysosomal storage diseases in which current research has identified that the dominant stored species is the lipid binding subunit c of mitochondrial ATP synthase. The research now centres on the underlying biochemical anomaly The approach will involve production of antibody against subunit c and immunogold electron microscopy using this and other specific antibodies against mitochondrial and other proteins of interest. Metabolic studies using radiolabelled probes or substrates are also envisaged. The laboratory is also involved in therapeutic experiments involving haemopoietic cell transplants.

Real Time Visual Inspection

A position is available in the Department of Production Technology under the leadership of Professors R M Hodgson and W Monteith. The successful candidate would be expected to have complementary hardware and software skills and have a developed interest in machine vision or automatic visual inspection systems Candidates with other relevant backgrounds will be considered. The project is concerned with making real time inspection systems a reality. Projects in hand are related to the inspection of a range of natural products including meat, fruit, timber and the application of transputer arrays for a flaw detection and control in paper and carpet manufacture. The fellow would be involved in original work related to a specific project. An important project involves the application of X-ray tomography to the determination of the internal structure of logs. The project is of significant commercial importance to the New Zealand economy.

Molecular Genetics — Costridium Acetobutylicum

A position is available in the Department of Microbiology & Genetics under the leadership of Professor D B Scott. The successful candidate will be expected to have a strong background in Molecular Genetics, Biochemistry or Microbiology. Clostridium acetobutylicum is able to utilize a variety of substrates, including the lactose in whey, for the production of the commercially important solvents, acetone butanol and ethanol. The B-galactosidase in Clostridium acetobutylicum is developmentally regulated, being expressed at a time in the fermentation coinciding with the switch from the acidogenic phase to the solventogenic phase. The B-galactosidase gene has recently been cloned and sequenced and shown to be controlled by an adjacent gene that acts as a positive regulator. The project proposed here is to investigate the biochemical role of this regulatory gene in controlling B-galactosidase gene expression. It is anticipated that this study will assist in identifying the signals which initiate solvent production in C. acetobutylicum. Fermentation studies will be carried out in the Biotechnology Department which houses the necessary fermentors for growing the organism.

Giardia and Giardiasis in New Zealand

A position is available in the Department of Microbiology and Genetics under the leadership of Dr T J Brown to conduct epidemiological and strain isolation and characterization studies on Giardia from New Zealand. It is intended to isolate and culture strains of Giardia from human and animal sources and develop an efficient method for the detection of antibody to Giardia in human and animal sera. Isolates of Giardia will be compared by means of SDS-PAGE and Western blotting. Proteins, which will allow strains to be distinguished and host specificity determined, will be identified. Monoclonal antibodies to Giardia tropgozoites and cysts will be developed to aid the detection of cysts in faeces. Experience with protozoa culture techniques, SDS-PAGE, use of DNA probes and monoclonal antibody techniques would be an advantage.

MASSEY UNIVERSITY POSTDOCTORAL RESEARCH FELLOWSHIPS

Development of monoclonal antibody probes to study the antigenic relationship of equine herpesviruses and the immune response of infected horses

A position is available in the Veterinary Virology Unit within the Department of Veterinary Pathology and Public Health under the leadership of Dr C R Wilks. The project aims to develop a panel of monoclonal herpesvirus to enable detailed antigenic comparisons to be made between the respective viruses. There are excellent facilities available for the project Extensive experience in the production of evaluation of monoclonal antibodies is required. Experience in veterinary virology would be an advantage but not essential.

Venison Production from Yearling Red Deer Stags

A position is available in the Department of Animal Science to design and carry out a programme aimed at increasing body growth and feed intake in yearling stags through immunisation against melatonin and LHRH, and to evaluate effects of testosterone implants in castrate stags. Excellent deer facilities are available and the project involves both field and indoor metabolism work. The successful candidate should have a PhD in ruminant nutrition. Previous experience in handling deer and some knowledge of endocrinology would be an advantage. The position is part of a team involving Professor T N Barry, Dr P R Wilson, and Dr R W Purchal.

A General Massey University Postdoctoral Fellowship

Applications are invited from suitably qualified persons for a Massey University Postdoctoral Fellowship an any of the areas of study at the University Applicants should have, or are about to complete, a PhD. The annual emolument payable for Postdoctoral Research Fellowships is currently NZ$35,000 pa and the Fellowship is tenable for a maximum period of two years

Further details of the above positions together with Conditions of Appointment are obtainable from **Mrs V B Bretherton, Personnel Section, Massey University, Palmerston North, New Zealand**, to whom applications, including a full curriculum vitae and the names of three referees, should be sent by *30 November 1989.* (W6450)E

nature

the widest international selection of jobs in science — EVERY WEEK

NSERC INTERNATIONAL POST-DOCTORAL FELLOWSHIP AT THE UNIVERSITY OF WATERLOO

The Department of Biology will be sponsoring one or more candidates for the 1990 competition for NSERC international fellowships (value $28,000 p.a.). The fellowships enable doctoral graduates from outside of Canada to spend up to two years engaged in research at a Canadian university. Successful candidates will be expected to become associated with one of the research programmes currently under investigation in the Department. The Department of Biology is a strong, research-oriented Department with 35 full-time faculty and over 100 graduate students and post-doctoral fellows. Research interests cover the spectrum of biological sciences.

Applications and/or enquiries should be directed to **Dr. R.G.H. Downer, Chairman, Department of Biology, University of Waterloo, Waterloo, Ontario, Canada, N2L 3G1.** Application deadline: *October 13, 1989.* (NW4163)E

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)

DEPARTMENT OF PHYSIOLOGY AND MEDICINE

JUNIOR RESEARCH FELLOWSHIP

Applications are invited from students in biochemistry or physiology who have, or expect to obtain, first or upper second class honours degrees and are motivated to study for a higher degree (Ph.D.). The project will be supervised by Dr E.S. Debnam and Dr S.K. Srai and will be concerned with developmental changes in iron binding proteins. The student will join a thriving interdepartmental group which is actively applying techniques of protein chemistry and molecular biology to investigate the relationship between developmental arrest and the inborn errors of metal metabolism (eg idiopathic haemochromatosis).

The conditions of the Fellowship are similar to SERC Phd Research Studentships It is for 3 years from October 1989 providing a maintenance grant of £4,690 per annum.

Further information about the project can be obtained from **Dr E.S. Debnam, Department of Physiology,** (01-794 0500 Ext: 4314) to whom applications, including a curriculum vitae and the names and addresses of two referees, should be sent as soon as possible. (1496)E

UNIVERSITY OF ABERDEEN

DEPARTMENT OF GENETICS AND MICROBIOLOGY

RESEARCH FELLOWSHIP

Applications are invited for a three-year Fellowship from 1 October 1989 for an AFRC funded position on the identification and isolation of Hypervariable DNA loci in Arabidopsis thaliana. Applicants should have experience in Recombinant DNA techniques or in genomic cloning Experience in plant molecular biology would be an advantage. The project is part of a major AFRC initiative on Arabidopsis molecular genetics and involves collaboration with other members of the program Salary within the range £10,458–£16,665 on the Research and Analogous Scale 1A (postdoctoral).

Further particulars and application forms from the **Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX** (tel 0224 273500) to whom applications (2 copies) should be returned by 29 September 1989 quoting reference number LW/048. (1485)E

UNIVERSITY OF CANTERBURY
New Zealand

POSTDOCTORAL FELLOWSHIPS
CHEMISTRY, GEOGRAPHY, ZOOLOGY

Applications are invited for three two-year University Grants Committee Post-Doctoral Fellowships.

CHEMISTRY:
Test methods for aluminium toxicity in soils. The research Fellow will be expected to participate in an ongoing project on the development of field tests for the toxic fraction of aluminium soils. (Code C89/01). Enquiries may be made direct to Dr H K J Powell, Department of Chemistry.

GEOGRAPHY:
Climatic change, sea level rise and hazards to coastal land, as these matters relate to ongoing research in the Department of Geography. (Code C89/02). Enquiries may be made direct to Dr R M Kirk, Department of Geography.

ZOOLOGY
Salmon stock development. The Fellow is expected to be competent in recombinant DNA technology. (Code C89/04). Enquiries may be made direct to Dr F Y T Sin, Department of Zoology.

Applicants must be aged 35 years or less and have been awarded, or have qualified for the award of, the degree of Doctor of Philosophy, or a degree equivalent thereto, or who have submitted a thesis for examination.

The emolument for each Fellowship shall be at a rate not exceeding the lowest step of the Lecturer salary scale (NZ$35,000 per annum).

Before submitting a formal written application, candidates are requested to obtain further particulars and Conditions of Appointment from the Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

Applications, quoting the appropriate Reference Code, close with A W Hayward, Registrar, University of Canterbury, Private Bag, Christchurch, New Zealand, on 29 September 1989. (W6453)E

THE UNIVERSITY OF AUCKLAND
New Zealand

POSTDOCTORAL FELLOWSHIP IN CHEMICAL KINETICS CANCER RESEARCH
(Two-year Term)

Department of Chemistry & Cancer Research Laboratory

Applications are invited for a Postdoctoral Research Fellowship, tenable for two years, associated with a study of the kinetics of nitro group reduction in a new class of nitro aromatics which have activity as radiosensitizers of hypoxic tumour cells and as hypoxia selective cyto-toxins.

A background in chemical kinetics and an awareness of the concepts of bio-orgamc chemistry would be preferred The project will be carried out collaboratively within the Department of Chemistry, the Cancer Research Laboratory and the Section of Oncology, Auckland School of Medicine.

Remuneration is a stipend of NZ$35,000 per annum, and an economy round trip airfare will be paid for the appointee.

Applications in the form of a CV including names and addresses of two scientific referees should be sent to Professor C J O'Connor, Department of Chemistry, University of Auckland, Private Bag, Auckland, New Zealand (Fax 64 9 302 1795) from whom further information is available.

Applications should be forwarded as soon as possible but not later than the closing date 30 September 1989

The University of Auckland is An Equal Employment Opportunity Employer. (W6454)E

FELLOWSHIPS
continued on pages 37, 38 & 39

ASSISTANTSHIPS

UNIVERSITY OF BRISTOL
DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a postdoctoral research assistantship, supported by the MRC, to work with Dr AP Halestrap on the role of pyrophosphate in the regulation of mammalian metabolism. The work will be carried out in a large well-equipped laboratory and will involve purification and kinetic studies of purified enzymes and transport proteins as well as analysis of metabolites in isolated mitochondria and tissue preparations Previous experience in any of these fields would be desirable but not essential.

The post, available immediately, is for up to two years in the first instance and will carry a starting salary of £10,458-£14,703 depending on age and experience

For further details telephone Bristol (0272) 303136 (ansaphone after 5pm) or write to the **Personnel Office, Senate House, Bristol University, Bristol BS8 1TH.** Please quote reference A677. Informal enquiries may be made to Dr Halestrap on Bristol (0272) 303030 ext. 4958.

The University is an Equal Opportunities Employer (1484)P

RESEARCH ASSISTANTSHIPS

available to work on the

REGULATION OF EUKARYOTIC GENE EXPRESSION

in the Department of Genetics and Microbiology at the University of Aberdeen

At least three positions are available to study gene structure and function in yeast Molecular, biochemical and genetic approaches are being used to analyse the organisation of genes within a eukaryotic chromosome, to dissect the 5'-leaders of specific mRNAs, and to characterize mRNA destabilizing elements. Posts are available at postgraduate and postdoctoral levels.

Applicants should have some research experience, perferably in molecular biology, biochemistry, genetics or microbiology. Salaries will either be on the IB scale (£9,816-£12,381) or the IA scale (£10,458-£16,665) depending upon the qualifications and experience of the successful applicants. The posts are available from late 1989. Informal enquiries on the projects may be directed to Dr Alistair Brown, telephone 041 339 8855 Ext 5110. Applications by full CV to the Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX quoting reference number LW/050. (1527)P

Institute of Plant Science Research
Cambridge Laboratory

PhD STUDENTSHIP IN GENETICS

Applications are invited for a three year Research Studentship tenable in the Cereal Research department of the IPSR, Cambridge Lab. The project sponsored by Plant Breeding International, Cambridge, will involve joint investigations of the genetical control of grain protein amount in wheat by applying modern methods of genetic analysis including the use of Restriction fragment length polymorphism techniques.

The studentship is tenable from 1st December 1989, and will initially be based at Cambridge. In March 1990 it will move to the new IPSR laboratory facilities in Norwich. About three months per year will be spent working in the Laboratories of Plant Breeding International in Cambridge. A grant of £4,475 will be paid in the first year and this will rise to £4,800 and £5,150 in the 2nd and 3rd years.

Candidates should have a first or second class honours degree in a biological science with a specialisation in genetics and/or molecular biology. A letter of application, together with a full CV should be sent as soon as possible to Dr J W Snape, IPSR Cambridge Laboratory, Trumpington, Cambridge CB2 2JB. (1483)F

UNIVERSITY OF ABERDEEN

Department of Environmental and Occupational Medicine

PhD STUDENTSHIP

A British Petroleum funded research studentship is available from October 1989 to study the physiology of escape from fire and other toxic environments and the influences of protective equipment. The work will have special emphasis on children and aircraft fires and will involve the use, modification and validation of a computer model.

Applicants should send their cv and the names of two referees as soon as possible to Dr J A S Ross, Environmental and Occupational Medicine, University Medical School, Foresterhill, Aberdeen, AB9 2ZD. (1524)F

OVER HALF A MILLION SCIENTISTS ARE LOOKING AT THIS SPACE.

nature

SHOULDN'T YOU BE FILLING IT?

UNIVERSITY COLLEGE OF SWANSEA

RESEARCH STUDENTSHIPS

Applications are invited for two studentships in the School of Biological Sciences to work on the genetics of species of the tropical freshwater fish *Tilapia*. The research, which is funded by the O.D.A. and supervised by Professor Beardmore and Dr Skibinski, involves work on sex-determining mechanisms with the aim of producing monosex clones in this important fish. Techniques include fish breeding and management, the techniques of gynogenesis and hormonal sex reversal, and work on DNA and isozyme analysis. The value of the studentships will be in line with SERC rates and they will be available from October 1, 1989.

Further details may be obtained from Professor J G Beardmore (0792 295382) and Dr Skibinski (0792 295390), School of Biological Sciences, University College of Swansea, Singleton Park, Swansea, SA2 8PP, to whom letters of application, including a full Curriculum Vitae should be addressed. (1487)F

British-Spanish Joint Research Programme (Acciones Integradas)

The British Council invites applications in all subject areas for inclusion in the 1990/91 programme (1 April 1990 to 31 March 1991). This scheme is run jointly with the Spanish Ministry of Education and Science in order to promote the development of co-operation between groups from universities, polytechnics and public sector research institutes in both countries, through the award of travel and subsistence grants for joint research projects. In 1990/91 the programme will receive support from the Science and Engineering Research Council for projects falling within its priority areas. Applicants must have already identified a Spanish project partner who should make a simultaneous application to the Spanish Ministry of Education and Science. Projects with awards for 1989/90 must re-apply if they wish to be considered for further support. Projects which have already received three years of support are not eligible for further awards.

Application forms and further information may be obtained from: Europe Division (Acciones Integradas), The British Council, 10 Spring Gardens, London SW1A 2BN. Telephone 01-389 4795.

Completed applications must be returned by Monday 13 November 1989.

The British Council

ROCKEFELLER FOUNDATION

AFRICAN DISSERTATION INTERNSHIP AWARDS

Doctoral students from sub-Saharan Africa are invited to apply to The Rockefeller Foundation for dissertation research support. The program enables Ph.D. students enrolled in U.S. and Canadian universities to return to Africa for extensive field research in areas relevant to economic development or poverty alleviation. Priority is given to research topics in the fields of agricultural, health, and life sciences, but other proposals are welcome.

Applicants are responsible for arranging affiliation with an African institution able to provide needed research support, such as laboratory facilities, access to study sites, and technical advice. The candidate's faculty advisor, the host institution in Africa, and the agency with primary responsibility for financing the student's graduate work must all send letters of endorsement.

Deadlines for applications are October 1, 1989 and March 1, 1990. Candidates should apply well in advance of the expected field work starting date.

For a full description of the competition and the application requirements, write to:

African Dissertation Internship Awards,
The Rockefeller Foundation,
1133 Avenue of the Americas,
New York, NY 10036.

CALL FOR
POSTERS AND SHORT REPORTS

"Advances in Gene Technology: The Molecular Basis of Immune Diseases"

January 21-26, 1990

The major gene technology conference of 1990 - **THE MIAMI BIO/TECHNOLOGY WINTER SYMPOSIA** is announcing its call for poster presentations that will appear in the conference proceedings as Short Reports and will be published by the ICSU Press and IRL Press.

Poster sessions are scheduled for January 22,23, and 24, 1990 at which time you may present your reports on 4' high x 6' wide corkboards provided for the occasion. The Short Report is the permanent record of your poster.

To have your Short Report considered for acceptance, you must be registered for the Symposia, and your Short Report must be received no later than **November 1, 1989.** Notification of acceptance will be sent within three weeks of the closing deadline.

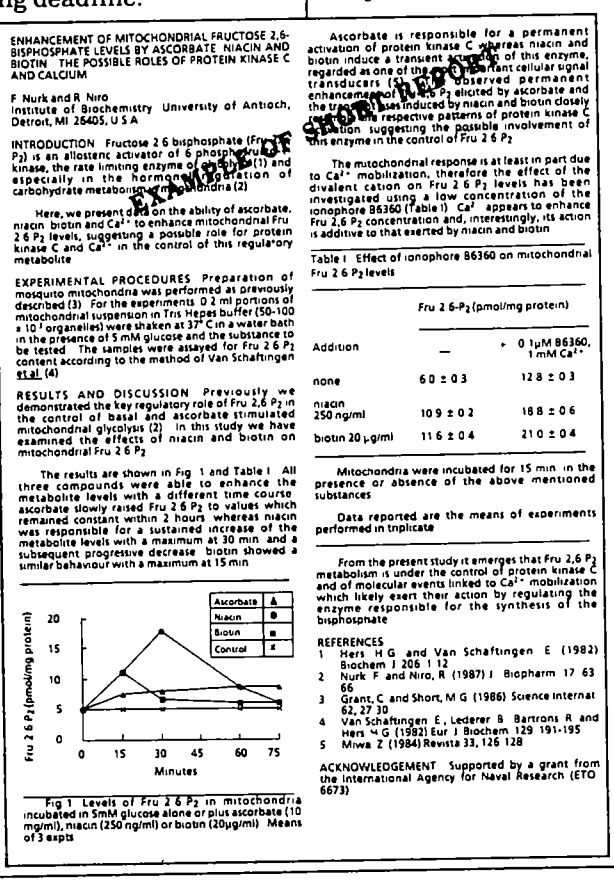
GUIDELINES FOR PREPARING SHORT REPORTS

To give your report the best chance of being accepted by the Symposia, try to follow these simple guidelines:

Legibility. The type style must be letter quality. Neatness counts.

Technical Specifications. Use the grid paper or type on two A4 or legal size sheets within a grid of 10 cm. wide and 28 cm. deep. Do not draw lines around your Report. Type size - 12 pitch. Single space. Number the pages in pencil on the reverse.

Length of Report. Two columns (2 grids of 10 x 28 cm) equals one page. **You must occupy two (2) columns in order to be considered for publication.** Anything under or over will automatically be rejected.



Headings. Capitalize headings for major sections either by topic, or organizationally, e.g. INTRODUCTION, DISCUSSION, REFERENCES.

Subheadings. Use capitals for initials and underline the phrase.

References. Cite these by number in the order in which they appear in the text. Collect the bibliography into a section at the end. **A bibliography is essential.**

Acknowledgements. These should appear last.

Make certain your work is represented at this important event. **Mail** your **UNFOLDED** Short Report to: MIAMI BIO/TECHNOLOGY WINTER SYMPOSIA, P.O. Box 016129, Miami, FL 33101, USA. (If using a courier service, to MIAMI BIO/TECHNOLOGY WINTER SYMPOSIA, Room 6054, Medical Research Building, University of Miami School of Medicine, 1600 NW 10th Ave., Miami, FL 33136, USA.)

ENHANCEMENT OF MITOCHONDRIAL FRUCTOSE 2,6-BISPHOSPHATE LEVELS BY ASCORBATE NIACIN AND BIOTIN THE POSSIBLE ROLES OF PROTEIN KINASE C AND CALCIUM

F Nurk and R Niro
Institute of Biochemistry University of Antioch, Detroit, MI 26405, U S A

INTRODUCTION Fructose 2 6 bisphosphate (Fru 2 6 P_2) is an allosteric activator of 6 phosphofructo kinase, the rate limiting enzyme of glycolysis (1) and especially in the hormonal regulation of carbohydrate metabolism in mitochondria (2)

Here, we present data on the ability of ascorbate, niacin biotin and Ca^{2+} to enhance mitochondrial Fru 2 6 P_2 levels, suggesting a possible role for protein kinase C and Ca^{2+} in the control of this regulatory metabolite

EXPERIMENTAL PROCEDURES Preparation of mosquito mitochondria was performed as previously described (3) For the experiments 0 2 ml portions of mitochondrial suspension in Tris Hepes buffer (50-100 x 10^7 organelles) were shaken at 37° C in a water bath in the presence of 5 mM glucose and the substance to be tested The samples were assayed for Fru 2 6 P_2 content according to the method of Van Schaftingen et al (4)

RESULTS AND DISCUSSION Previously we demonstrated the key regulatory role of Fru 2,6 P_2 in the control of basal and ascorbate stimulated mitochondrial glycolysis (2) In this study we have examined the effects of niacin and biotin on mitochondrial Fru 2 6 P_2

The results are shown in Fig 1 and Table I All three compounds were able to enhance the metabolite levels with a different time course ascorbate slowly raised Fru 2 6 P_2 to values which remained constant within 2 hours whereas niacin was responsible for a sustained increase of the metabolite levels with a maximum at 30 min and a subsequent progressive decrease biotin showed a similar behaviour with a maximum at 15 min

Fig 1 Levels of Fru 2 6 P_2 in mitochondria incubated in 5mM glucose alone or plus ascorbate (10 mg/ml), niacin (250 ng/ml) or biotin (20µg/ml) Means of 3 expts

Ascorbate is responsible for a permanent activation of protein kinase C whereas niacin and biotin induce a transient activation of this enzyme, regarded as one of the most important cellular signal transducers (5) The observed permanent enhancement of Fru 2 6 P_2 elicited by ascorbate and the transient rises induced by niacin and biotin closely resemble the respective patterns of protein kinase C activation suggesting the possible involvement of this enzyme in the control of Fru 2 6 P_2

The mitochondrial response is at least in part due to Ca^{2+} mobilization, therefore the effect of the divalent cation on Fru 2 6 P_2 levels has been investigated using a low concentration of the ionophore B6360 (Table I) Ca^{2} appears to enhance Fru 2,6 P_2 concentration and, interestingly, its action is additive to that exerted by niacin and biotin

Table I Effect of ionophore B6360 on mitochondrial Fru 2 6 P_2 levels

	Fru 2 6-P_2 (pmol/mg protein)	
Addition	—	+ 0 1µM B6360, 1 mM Ca^{2+}
none	6 0 ± 0 3	12 8 ± 0 3
niacin 250 ng/ml	10 9 ± 0 2	18 8 ± 0 6
biotin 20 µg/ml	11 6 ± 0 4	21 0 ± 0 4

Mitochondria were incubated for 15 min in the presence or absence of the above mentioned substances

Data reported are the means of experiments performed in triplicate

From the present study it emerges that Fru 2,6 P_2 metabolism is under the control of protein kinase C and of molecular events linked to Ca^{2+} mobilization which likely exert their action by regulating the enzyme responsible for the synthesis of the bisphosphate

BIOTECHNOLOGY: SCIENCE, EDUCATION AND COMMERCIALIZATION

An International Biotechnology Symposium

University of Florida
Gainesville, Florida
December 3-6, 1989

PURPOSE: Assessment of biotechnology science and business by focusing on scientific accomplishments, commercialization, global perspectives, and science education.

TOPICS OF DISCUSSION: Biotechnology in plants, microbes, marine life, animals, recombinant vaccines, and biochemical engineering. Commercialization in PCR technology, human genome, human medicine products, bioprocessing, and biopesticides. Regulation and licensing and developing biotechnology inventions and discoveries. Global perspectives in Latin America, India and South-Asia, Taiwan and Australia, and EMBO and UNESCO biotechnology activities. Science education including NSF's role and other federal agencies. Progress of the human genome project.

SPEAKERS: The symposium provides a forum for exchange among business, academia and government. The principal speakers include:

Jorge E. Allende, *University of Chile*
Charles R. Cantor, *Human Genome Ctr, Lawrence Berkeley Lab*
William Chang, *Taiwan Biotechnology Development Center*
Mary Clutter, *National Science Foundation*
Gary Cobon, *Biotechnology Australia PTY LTD*
Robb Fraley, *Monsanto Company*
Frederico Mayor, *The Director-General, UNESCO*
Douglas K. McCormick, *Bio/Technology*
Victor McKusick, *Johns Hopkins*
Jan C. Meneley, *Evans BioControl, Inc.*
Yves Moreau, *Rhone Merieux*
Dennis A. Powers, *Hopkins Marine Station*
John T. Preston, *Technology Licensing, MIT*
S. Ramachandran, *Sec. Biotechnology, Gov't of India*
Gordon Reeves, *The Lancet*
Jeffrey Rosen, *Baylor College of Medicine*
Mary B, Rowe, *University of Florida*
John Sninsky, *Cetus Corporation*
Gregory Stephanopoulos, *Chemical Engineering, MIT*
John Tooze, *European Molecular Biology Organization*
James F. Walter, *W. R. Grace & Co.*
Tilahun Yilma, *University of California at Davis*
Alvin Young, *Agricultural Biotechnology, USDA*
J. G. Ziekus, *Michigan Biotechnology Institute*

Ms. Lenie Breeze, Assistant Director, Biotechnology Institute, University of Florida, One Progress Blvd., Box 26, Alachua, FL 32615 (904/462-3904). (NW4133)M

FELLOWSHIPS continued

JOHN H. SUNUNU ENDOWED FELLOWSHIP in Basic Science Research

St Jude Children's Research Hospital, a premier research center for catastrophic diseases in children and biomedical research, offers the **John H. Sununu Endowed Fellowship in Basic Science Research** The fellowship is available to Ph.D. or M.D. investigators who wish to gain training and experience in one of the specialty areas of biomedical research at this center Research opportunities are available in the departments of biochemistry, immunology, pharmacology, tumor cell biology, and virology/molecular biology St Jude Hospital is academically affiliated with the University of Tennessee Center for the Health Sciences

John H. Sununu Endowed Fellowship awards are made for up to two years. Awards are based on merit, recommendations and the promise of a productive career in basic science research.

Application deadline	1 January 1990
Decision	15 February 1990
Beginning date	1 July 1990
Stipend	Competitive

The John H. Sununu Endowed Fellowship in Basic Science Research was established by the American Lebanese Syrian Associated Charities/ St Jude Children's Research Hospital Boards of Governors and Directors in honor of Mr Sununu's contributions to the political life of the nation as an American of Arabic ancestry.

St Jude Children's Research Hospital is an Equal Opportunity/Affirmative Action Employer.

COURSES & CONFERENCES

FIRST INTERNATIONAL CONFERENCE ON HUMAN ANTIBODIES AND HYBRIDOMAS

April 18-20, 1990
Orlando (Lake Buena Vista), Florida, USA
Programme Chairman:
Mark C. Glassy, PhD, Biotechnetics

The scientific program will consist of keynote lectures by invited speakers, contributed papers, and poster presentations emphasizing all aspects of human hybridoma and antibody technology, including fundamental research, applied science, and clinical applications.

Deadline for abstracts: October 15, 1989

Contact: S. L. Patterson, Butterworths, 80 Montvale Ave., Stoneham, MA 02180, USA. 617-438-8464, ext 234 or 242. (NW4165)C

McGill University Conference on:

REGULATION OF EUKARYOTIC DNA REPLICATION

March 5-8, 1990
Montréal, Québec, Canada

M Zannis-Hadjopoulos and G.B Price (Organizers)

Topics will include

- **Regulation of Viral and Cellular DNA Replication;**
- **Eukaryotic Origins of DNA Replication;**
- **Initiation of DNA Replication.**

A group of international experts in this field have been enlisted as participants in Plenary Sessions Abstract Deadline: November 1, 1989

For further information, please contact:

STA FELLOWSHIPS

Postdoctoral Fellowships in Japanese Government Laboratories

The Japanese Science and Technology Agency (STA) is offering postdoctoral fellowships to scientists and engineers of the countries listed below for periods of 6 months to 2 years to be held in any Japanese national laboratory (excluding university and university-affiliated laboratories). Over one hundred Japanese research laboratories covering almost all areas of science, engineering and medicine are participating in the scheme.

The fellowships are open to young PhD holders of under 35 (although older researchers will be considered) from universities, research councils, government research laboratories and industry. Any science or engineering discipline will be considered except military R & D. Applicants will be required to supply a letter of invitation from their Japanese host institution (the organizations listed in Table 1 provide help in contacting suitable host institutions).
Those in the final stages of a PhD may also apply.

There are no closing dates but candidates are encouraged to submit their applications as soon as possible. Fellowships for fiscal 1989 must be taken up by March 1990.

FELLOWSHIP AWARDS

Fellowships include round-trip air tickets (economy class) and the following tax-free allowances:

1) Living allowance: ¥270,000 (about US$2,000) a month
2) Family allowance: ¥ 50,000 a month
3) Housing allowance: up to ¥100,000 a month
   Apartments will normally be provided to awardees. The apartment floor area is 40 m^2 for awardees unaccompanied by their family and 60 m^2 for awardees to stay with their family in other than metropolitan areas such as Tokyo. If an awardee prefers to use a larger apartment because of the family size or otherwise ¥100,000 maximum per month may be paid as housing allowance; any shortfall is to be borne by the awardee.
4) International relocation allowance: ¥200,000
5) Travel allowance: ¥100,000 a year
   (within Japan)
6) Japanese language lesson courses are to be provided free of charge to the STA Fellowship awardees and their family members in Tsukuba area. Those who live in places other than the Tsukuba area will be entitled to reimbursement of Japanese language school tuition up to a specified amount.
7) Excursions or the like will be held to help make the Fellowship awardees and their family members in Tokyo/Tsukuba areas familiarized with Japan's culture, tradition and history.

In addition, ¥1,480,000 per year will be paid to the host institute to cover research costs and insurance for researchers will be paid by JISTEC during their stay in Japan to cover medical care.

APPLICATION PROCEDURE FOR STA FELLOWSHIP

Management of the STA Fellowship, including recruitment of candidates, is entrusted to the Japan International Science and Technology Exchange Center (JISTEC).

Responsible organizations overseas which represent the governments of their respective countries are given in Table 1.

A researcher wishing to be awarded the STA Fellowship should apply to the responsible organization in his/her country. Candidates are required to contact the desired host institute and obtain a letter of acceptance before filling an application with their government. Further information regarding the STA Fellowship and host Institutes is available from the responsible organizations.

A researcher whose country is not listed in Table 1 could contact a Japanese host institute directly, which in turn may recommend the reseacher to JISTEC as a candidate for STA Fellowship.

Fig. 1 shows the process from consult/contact to receipt of award.

INSTITUTE OF PSYCHIATRY
UNIVERSITY OF LONDON

POST-DOCTORAL COURSE IN NEUROSCIENCE

This evening lecture course is intended to provide a basic introduction to Neuroscience across a broad range of topics from molecular neurobiology to behavioural psychology. Clinical topics on psychiatric and neurological disorders will also be covered.

The course is aimed primarily at research workers (eg PhD students, technicians, postdoctoral researchers and clinicians) working in the neuroscience field but is open to anyone interested in broadening their background knowledge of Neuroscience. Major topics will be:

Neuroanatomy and Pathology
Neurochemistry/Neurophysiology/Neuropharmacology
Molecular Neurobiology and Neurogenetics
Behavioural Neuroscience
Neuroimmunology
Development and Degeneration of the Nervous System
Vision
Computer Models of the Brain
Neurology and Psychiatry

The course will be held at the Institute of Psychiatry on Tuesday evenings in term time from 26th September, 1989 to 12th June, 1990.

For further details please contact **The Secretary, Department of Neuroscience, Institute of Psychiatry, De Crespigny Park, London SE5 8AF.** Telephone 01 703 5411 Ext 3259. (1504)C

MOLECULAR CONTROL OF DEVELOPMENT

(The 17th Aharon Katzir-Katchalsky Conference).

January 7–12, 1990, Ein Gedi, Dead Sea, Israel:

Organizing Committee: B. Hess, L. Sachs, J. Schell

Speakers from outside Israel include:

S. BENZER, J. FOLKMAN, A. GARCIA-BELLIDO, P. GRUSS, J. GURDON, B. HESS, N. LE DOUARIN, E.B. LEWIS, R.C. MULLIGAN, D. NATHANS, C. NUESSLEIN-VOLHARD, T.S. OKADA, B. PIERCE, F. RUDDLE, J. SCHELL, M. STOKER, T. SUGIYAMA, H. ZUR HAUSEN

For application and further information please contact: **Mrs. Ruth Goldstein, The Aharon Katzir-Katchalsky Center, The Weizmann Institute of Science, Rehovot 76100, Israel.**

MOLECULAR ENDOCRINOLOGY AND TECHNIQUES FOR HORMONE ACTION

February 19-23, 1990

This course will consist of lectures in methodology with comprehensive syllabus covering receptors, gene transcription, mRNA and protein synthesis, recombinant DNA, protein hormones and cyclic nucleotides.
Co-directors: M. R. Hughes and B. W. O'Malley.
Fee: $365 ($245: fellows and students).
For further information contact: **Bonnie Cuthbert, Department of Cell Biology, Baylor College of Medicine (713)-798-6200.**
DEADLINE—February 2, 1990. (NW4144)C

GRANTS & SCHOLARSHIPS

THE AUSTRALIAN NATIONAL UNIVERSITY

Scholarships for PhD Degree Course in 1990

Persons who hold, or expect to hold, a bachelor degree with at least upper second-class honours or equivalent from a recognised university and who have a capacity for research are invited to apply for Australian National University PhD scholarships tenable over a wide range of subjects in the Social Sciences and Humanities and Applied Physical, Mathematical, Medical, Chemical, Biological, Information, Earth and Engineering Sciences. Scholarships are available in the Institute of Advanced Studies which consists of the Research Schools of Physical Sciences, Biological Sciences, Social Sciences, Pacific Studies, Chemistry, Earth Sciences, the John Curtin School of Medical Research and Mount Stromlo and Siding Spring Observatories and in the Faculties of Arts, Asian Studies, Economics and Commerce, Law and Science or in one of the University Centres.

Scholarship Benefits. The basic stipend payable will be $A12,734 per annum (tax free), with additional allowances for dependent children and housing assistance for married scholars. In addition, return economy-standard airfares and a grant towards removal expenses are normally provided. (The latter will not be provided for Australian citizens overseas who are eligible for Australian Government Research Awards.) Successful applicants may also be awarded a full or partial fee waiver scholarship.

Tenure. Scholarships are normally tenable for three years and may be taken up at any time of the year.

There is no set closing date, but applicants from outside Australia are advised to apply at least six months before they expect to be available to take up a scholarship, if offered.

Full particulars and application forms are available from the Registrar, The Australian National University, GPO Box 4, Canberra ACT 2601, Australia; or from Appointments (36816), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF. (W6455)H

THE ROBERT A WELCH FOUNDATION

CONFERENCE ON CHEMICAL RESEARCH XXXIII

MEMBRANE PROTEINS: TARGETING AND TRANSDUCTION

OCTOBER 23-24, 1989

THE WESTIN OAKS HOTEL, HOUSTON, TEXAS

PROGRAM

Monday, October 23, 1989

SESSION I

JOSEPH L. GOLDSTEIN, Presiding Scientific Advisory Board Member

8 30 **JACK S. JOSEY**, President, Welcoming of Guests
8 35 **JOSEPH L. GOLDSTEIN**, Introductory Remarks

PROTEIN TRANSLOCATION ACROSS MEMBRANES
8 45 **GÜNTER BLOBEL**

THE SORTING OF RESIDENT ER PROTEINS FROM SECRETED PROTEINS
9 30 **HUGH PELHAM**

PROTEIN TRANSPORT IN THE GOLGI
10:45 **JAMES ROTHMAN**

TRANSLOCATION OF PROTEINS ACROSS MITOCHONDRIAL MEMBRANES
11·30 **GOTTFRIED SCHATZ**

SESSION II

GEORGE PALADE, Presiding Chairman

1 30 Introductory Remarks by **GEORGE PALADE**

FOLDING AND SHEPHERDING OF PROTEINS TO THE CELL SURFACE
1 45 **JOSEPH F. SAMBROOK**

RECEPTORS THAT MEDIATE ENDOCYTOSIS
2.30 **MICHAEL S. BROWN**

ROLE OF MANNOSE 6-PHOSPHATE RECEPTORS IN LYSOSOMAL ENZYME TARGETING
3 45 **STUART KORNFELD**

STRUCTURE/FUNCTION STUDIES ON MEMBRANE GLYCOPROTEINS FROM HUMAN CELLS, TRYPANOSOME SURFACE, AND INFLUENZA VIRUS
4:30 **DON C. WILEY**

Tuesday, October 24, 1989

SESSION III

KONRAD BLOCH, Presiding Chairman

8:30 Introductory Remarks by **KONRAD BLOCH**

THE ADRENERGIC RECEPTORS
8.45 **ROBERT J. LEFKOWITZ**

G PROTEINS AND REGULATION OF ADENYLYL CYCLASE
9:30 **ALFRED G. GILMAN**

INOSITOL LIPIDS AND CELL SIGNALLING
10·45 **MICHAEL J. BERRIDGE**

NON-RECEPTOR PROTEIN-TYROSINE KINASES AND SIGNAL TRANSDUCTION
11 30 **HIDESABURO HANAFUSA**

SESSION IV

DANIEL KOSHLAND, Presiding Chairman

1 00 Introductory Remarks by **DANIEL KOSHLAND**

FROM PHYSICAL CHEMISTRY OF DNA TO GENES CODING FOR ION CHANNELS
1 15 **NORMAN DAVIDSON**, 1989 WELCH AWARDEE

MOLECULAR INSIGHTS INTO THE FUNCTION OF IONIC CHANNELS
2.15 **SHOSAKU NUMA**

FROM PHOTON TO NERVE IMPULSE
3 30 **LUBERT STRYER**

HOW BACTERIA THINK
4 15 **MELVIN SIMON**

Address _____

Advance registration will be acknowledged and accepted in order of their receipt, to within the capacity of the available space

Make your hotel reservations directly with The Westin Oaks Hotel, Telephone No 1-800-228-3000 or 713-960-8100 x6990, prior to October 6, 1989

Please return by October 6 to: **Kimberly Nelson**
The Robert A. Welch Foundation
4605 Post Oak Place, Suite 200
Houston, Texas 77027 (NW4142)C

SEMINARS & SYMPOSIA

1st HIGH PERFORMANCE ELECTROPHORESIS SYMPOSIUM

16th October 1989

Kastens Hotel Luisenhof, Luisenstraße 1/3, 3000 Hannover 1, West Germany
Telephone 0511-12440

The introduction in late 1988 of the HPE®-100 HIGH PERFORMANCE ELECTROPHORESIS SYSTEM has brought this exciting technique to the forefront of biological separations.

BIO-RAD is organising the 1st HPE Users symposium to allow scientists to listen to the first hand experiences of several leading people in this field. The Symposium is designed to encourage a detailed exchange of information on the technique and its many applications.

Invited speakers include:

Stellan Hjerten	*University Uppsala, Sweden*
Ferenc Kilar	*Medical University of Pecs, Hungary*
David Begley	*Kings College London, England*
Joachim Klose	*Freie Universitat Berlin, Federal Republic of Germany*
Rolf Herb	*Boehringer Mannheim, Tutzing, Federal Republic of Germany*
Wolfgang Thormann	*University Bern, Switzerland*
Tim Wehr	*BIO-RAD Richmond, United States of America*

The conference will be in English.

For more information and registration please contact:
BIO-RAD LABORATORIES GMBH
Dept. BIOANALYTIC
Dachauer Straße 511
8000 München 50 West Germany
Telephone 089/149905-0
Beate Joppien

Registration Deadline: **Registration up to the 30th September 1989**

Abstracts Deadline: **Abstracts (200-300 words in English) to be received by 31st August 1989**

Symposium Fees: **DM 300,00 or US $160,000**
Fee includes:
Attendance of lecture sessions
Abstracts
Symposium proceedings (available within three months of the Symposium)
Buffet Lunch and Coffee breaks
Guest entrance ticket to the BIOTECHNICA Exhibition (17th-19th October 1989) Messegelände, Hannover

COURSES & CONFERENCES

European School of Oncology

THE EUROPEAN SCHOOL OF ONCOLOGY

1990

The European School of Oncology will be organizing for 1990 the following activities:

Residential Courses to be held at Orta San Giulio, Lake Orta, Italy

Leukaemias (2–6 April), Chest Tumours (7–11 May), Radiotherapy 2000; Research Strategies for the Next Decade (11–15 June), Methodology of Clinical Trials (10–14 September), Breast Cancer (8–12 October).

Seminars to be held on San Servolo Island, Venice, Italy

Advanced Bladder Cancer (17–18 April), Magnetic Resonance Imaging and Spectroscopy in Oncology (29–30 May), Interleukins (5–6 June), Breast Reconstruction (21–23 June), Pain Treatment in Oncology (26–27 June), Cancer, Occurence & Causes (11–13 September), Radiolabelled Antibodies in Clinical Oncology (25–26 September), Drug Delivery in Cancer Care (2–3 October), Air Pollution and the Risk of Cancer (11–12 October), Cancer and the Immune System (23–24 October), Neurological Adverse Reactions to Antineoplastic Chemotherapy (13–14 November).

For further details on the above activities, please see the 1990 First Announcement inserted with this issue of *Nature*.

European School of Oncology
Via Venezian, 1
20133 Milano
Italy
Tel: 39/2/235923 or 2364283 or 2360410
Fax: 39/2/2664662 (W6477)C

Hoping to change jobs?

The widest selection of international science vacancies is published in Nature each week.

Make sure that you are the first to see them by taking your own subscription to Nature.

THIRTEENTH ANNUAL BRISTOL-MYERS AWARD FOR DISTINGUISHED ACHIEVEMENT IN CANCER RESEARCH

Bristol-Myers Company presents an annual award to a scientist making an outstanding contribution in cancer research. The candidates for the award are to be nominated by medical schools, free-standing hospitals and cancer research centers.

AWARD: $50,000 U.S.

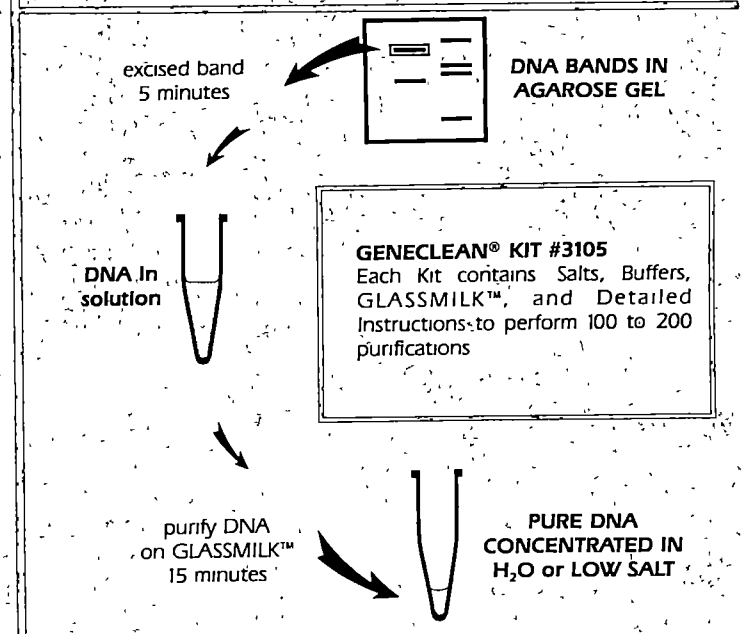
Deadline for Receipt of Nominations: **December 1, 1989**

Announcement of Award Recipient: **Spring 1990**

SELECTION COMMITTEE

ALAN C. SARTORELLI, PH.D.	***Selection Committee Chairman,*** *Yale Comprehensive Cancer Center*
ROBERT C. BAST, JR., M.D.	*Duke Comprehensive Cancer Center*
ROBERT L. COMIS, M.D.	*Fox Chase Cancer Center*
GEORGE KLEIN, M.D.	*The Karolinska Institute*
IRWIN H. KRAKOFF, M.D.	*University of Texas M. D. Anderson Cancer Center*
JOSHUA LEDERBERG, PH.D.	*The Rockefeller University*
ALBERT H. OWENS, JR., M.D.	*The Johns Hopkins University School of Medicine*
JOSEPH V. SIMONE, M.D.	*St. Jude Children's Research Hospital*
RICHARD J. STECKEL, M.D.	*Jonsson Comprehensive Cancer Center, UCLA*
HARUO SUGANO, M.D.	*Japanese Foundation for Cancer Research*
E. DONNALL THOMAS, M.D.	*Fred Hutchinson Cancer Research Center*
JAMES D. WATSON, PH.D.	*Cold Spring Harbor Laboratory*

Rules and official nomination forms are available from: Secretary, Award Committee, Bristol-Myers Award for Distinguished Achievement in Cancer Research, 345 Park Avenue, Suite 4100, New York, NY 10154, or (212) 546-5709. (NW4173)N



GENECLEAN®

PURIFY DNA FROM AGAROSE IN 20 MINUTES

- **REMOVE AND PURIFY DNA FROM AGAROSE GELS FAST** 20 minutes from Gel-Band to purified DNA in water or TE
- **REMOVE EXCESS LINKERS, PCR PRIMERS, UNREACTED LABELLED NUCLEOTIDES and/or DESALT AND CONCENTRATE DNA SOLUTIONS, EVEN THOSE IN PHOSPHATE, FAST** 15 minutes without columns, alcohol precipitations or organic extractions
- **ELIMINATE ENZYME-INHIBITING IMPURITIES FROM DNA SOLUTIONS FAST** 15 minutes to remove protein, small RNA and other enzyme-inhibiting impurities from DNA solutions For example, remove RNA and protein from crude mini-plasmid cleared-lysates without protease, RNase, organic extractions or alcohol precipitations
- **ELIMINATE NEED FOR ALCOHOL PRECIPITATION OF DNA** 15 minute **GENECLEAN** process serves the same purpose as alcohol precipitation of DNA, often with increased recovery
- **REMOVE TRACES OF ORGANIC SOLVENTS FAST** 15 minutes to remove residual enzyme-inhibiting phenol, chloroform or ether from extracted solutions of DNA
- **"QUICKCLONE" FROM HIGH MELTING-POINT AGAROSE GELS.**

DNA TREATED WITH GENECLEAN® IS free of RNA, proteins and other contaminants that inhibit enzymes and is a ready substrate for restriction enzymes, polymerases, ligases and kinases Single and double stranded sequencing reactions are remarkably free of ghost bands caused by self-priming activity of RNA The highly pure DNA transforms procaryotic or eucaryotic cells with high efficiency

THE GENECLEAN® KIT provides excellent recovery of single and double stranded DNA and it is not inhibited by SDS, organic solvents or protein.

BIO 101 WANTS YOU TO BE PLEASED WITH ITS PRODUCTS
If you are not satisfied with the performance of **GENECLEAN® KIT** return it within 30 days and we will refund your payment immediately

CLOUDS AND CLIMATE CHANGE

IMMUNOLOGY/MONOCLONALS
product review

documentation costs soaring?

We bring them down to earth!

Electronic instant photographic camera
for quick and inexpensive documentation of:

- ○ DNA electrophoresis gels
- ○ Protein gels
- ○ TLC plates

The camera's thermoelectrically cooled CCD image sensor and specially developed interference filters yield excellent discernibility of low-light fluorescent patterns. The images are stored in a frame buffer and displayed on a television monitor. If desired, contrast amplification, edge enhancement and baseline subtraction may be performed on the stored images.

Hardcopies are printed out on high-resolution thermal paper within 20 seconds.

The images can be transmitted to a personal computer for further processing.

QIAGEN
the fastest way to pure plasmids

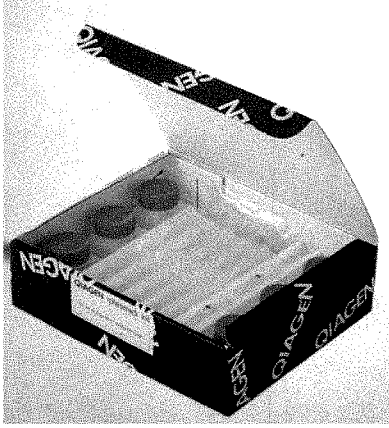
12 high purity plasmid preps in less than an hour ?

Yes, with one of the new QIAGEN >plasmid< kits

matching CsCl purity

with new, short & simple protocols

mini, midi or maxi scale.



QIAGEN Hi purity >plasmid< kits contain our proprietary anion exchange resin QIAGEN in disposable plastic tips, together with all the buffers and solutions required to go from overnight cultures to pure plasmids in 50 minutes (for minipreps, 90 min for maxi preps).

Hi purity kits are available for either 25 Mini- or, 25 Midi or, 10 Maxi preps of DNA of a purity equivalent to CsCl gradients. A fourth kit, QIAscreen, for 300 Mini preps of "screening" quality produces plasmid DNA ideal as a substrate for restriction analysis.

High recoveries
Excellent reproducibility
Non-toxic reagents

All you need to get started is a

QIAGEN >plasmid< kit

Mini preparation (plasmid DNA)
Hi purity ("for sequencing")

This protocol is designed for 1-3 ml cultures of E.coli.

Procedure

1. *Resuspend the bacterial pellet in 0.3 ml of buffer P1.*
2. *Add 0.3 ml. of buffer P2, incubate at room temp. for 5 min.*
3. *Add 0.3 ml of buffer P3, centrifuge at 4°C for 15 min.*
4. *Apply the supernatant to a QIAGEN-tip 20, pre-equilibrated with 1.0 ml of buffer QB.*
5. *Wash the QIAGEN-tip 20 with 2 x 1.0 ml of buffer QC, and elute the DNA with 0.8 ml of buffer QF.*
6. *Precipitate the DNA with 0.8 volumes of isopropanol.*

QIAGEN

INFORMATION AT THE HIGHEST LEVEL...

Is well within your reach.

Current Contents on Diskette*™/*Life Sciences, the most comprehensive life sciences journal information system around, is now available at a **new lower price.**

This weekly electronic information system gives you access to the tables of contents from over 1200 journals in your field. Along with the power to scan them as fast as you like.

Using your own custom profiles, you'll search each week's data with maximum efficiency and accuracy. Plus you can print out search results, export records in several formats, even generate orders for article reprints — automatically.

Four weeks free

If, after four weeks, you're not completely satisfied, simply write cancel on your invoice. Keep the four diskettes and retrieval software, free.

To order, call toll-free: 800-523-1850 ext. 1483
or write to one of the addresses below.

Reach for the highest level...and pay a lower price.

Available for IBM, compatibles, Macintosh and NEC, in two levels of coverage — J-1200 or J-600.

Now DNA sequencing has made the same progress

Communications have certainly come a long way since the carrier pigeon. Information can be sent from any location to anywhere in the world. By phone, fax or electronic mail. Instantly.

Now DNA sequencing has made the same breakthrough with Amersham's innovative range of sequencing products.

- Multiwell — the remarkable new sequencing system; the fastest, most convenient technique for sequencing DNA.
- Sequencing nucleotides — ^{32}P and ^{35}S radiolabel, HPLC pure and routinely tested in sequencing applications.
- Enzymes — for DNA sequencing, restriction and modification, including T7, Taq and Klenow DNA polymerases.
- Autoradiography films — Hyperfilm-βmax and Hyperfilm-MP films, optimized for biological applications.
- Staden-Plus — sequence data analysis software for PCs.
- Autoreader — rapid, automatic sequencing autoradiograph reader capable of reading 10 clones in under 15 minutes.

Contact your local Amersham office for full details.

◀ Formation of 'fall-streak holes' when part of a water cloud freezes highlights the fact that cirrus (ice cloud) particles are large enough to have a significant fall-speed, while most water cloud droplets remain in brownian suspension. Photo: over Totland, Isle of Wight/R. K. Pilsbury. See pages 132 and 104.

THIS WEEK

Fantastic voyager

More striking images from Voyager's passage through the Neptune system, page 95. Shown here, a 600-km (360-mile) dark

feature and impact crater on a low-lying plain on Triton.

Drug mechanism

The relaxation of smooth-muscle cells by beta-adrenergic agonists such as the bronchodilator isoprenaline (isoproterernol) is caused by an increase in the open-state probability of Ca-dependent channels, which may be mediated by phosphorylation of channel-related proteins by protein kinase A. Page 152.

Yeast breaks code

The 'universal' genetic code is known not to be truly universal — some termination codons being translated — but on page 164, Kawaguchi *et al.* report an example of a 'sense' codon encoding an amino acid different from that of the universal code in the whole cell. In the yeast *Candida cyclindracea*, leucine-coding CUG is translated as serine.

Developmental genetics

A letter published on page 156 fills in a blank in the set of correspondences between mammals and flies with respect to the genetic specification of the body plan. The vertebrate homoeobox gene *Hox 2.9* is found to be expressed in a single segment in developing mouse brain, simultaneously with *Krox-20* expression in the flanking segments.

Fifth column

A laboratory experiment to detect the hypothesized but elusive 'fifth force' may be one consequence of calculations aimed at describing asymmetric monopoles. Page 131.

Save the panda

An opportunity to help restore China's panda population via a tree planting scheme should not be missed, say Alan Taylor and Qin Zisheng, page 111.

Protein foldases

Biochemical analysis of the state of proteins newly transported into mitochondria provides the first direct evidence that 'molecular chaperonin', hsp60, acts as an ATP-dependent catalyst of protein folding. Page 125.

Answer in the soil

One way of determining past ecological conditions is to estimate the proportions of C3-type photosynthetic route plants to C4 (often grassland) plants by examining geological deposits. Some of the doubts about the accuracy of this method are dispelled by new work (page 138) on carbon isotopes in modern soils.

Two and counting

Now there are two members in the family of neuronal survival factors. The gene encoding a recently identified brain-derived neurotrophic factor has been isolated and shown to have high sequence similarity to nerve growth factor. Page 149.

A target for killers?

Zeta subunit of the T-cell receptor is present on the surface of tumour-lysing killer cells, in association with clonally variable proteins that may be its elusive antigen receptor, pages 159 and 108.

EASY One reagent, that's all you need to obtain high efficiency transfections. Simply mix Lipofectin™ with DNA or RNA and add to cells. Lipofectin™ does all the work – it complexes with Nucleic Acids and fuses with cells for cationic liposome mediated transfection.

LIPOFECTIN™ REAGENT FOR TRANSFECTION OF CULTURED CELLS

VERSATILE Effective for both transient expression and stable integration of transfected DNA. Numerous lines of human, monkey, mouse, rat, hamster, canine, chicken, bovine, duck, quail and insect cells have been successfully transfected using Lipofectin™ Reagent.

HIGHLY EFFICIENT

Often up to 100 X more efficient than other methods[1]. Compare the results with calcium phosphate.

HYBAID

THE HYBAID THERMAL REACTOR

For Absolute Control of Temperature Cycling

WHY ABSOLUTE CONTROL?

The new Hybaid Thermal Reactor is a microprocessor controlled heating and cooling block designed to automate numerous molecular biology experiments. It may be operated by controlling the temperature of the low thermal mass copper block or uniquely by using a thermocouple located in a dummy tube to ensure absolute control of sample temperature.

The Thermal Reactor uses a novel and patented method of very rapidly raising and lowering the temperature that is elegantly simple in design and ensures excellent reliability. As there is no need for external cooling supplies it is virtually maintenance free.

- Faster cycle times.
  Maximum heating greater than 2.5°C/sec.
  Maximum cooling greater than 2.5°C/sec.
- Temperature range 4°C to 99°C.
- Absolute control of sample temperature.
  Remote sample thermocouple not only monitors, but controls the temperature and allows automatic ramping.
- High sample capacity takes 54 by 0.5ml microcentrifuge tubes.
- Very low sample temperature variation even at critical temperatures.
  Block uniformity +/- 0.5°C.
- Simple to program.
  25 programs available. Non-identical cycles, long dwell times, program hold, allows the most sophisticated protocols to be performed.
- Very safe to use.
  The permanent heat shield means block is never exposed.

Hybaid Limited, 111-113 Waldegrave Road, Teddington, Middlesex TW11 8LL, U.K.

Custom Peptides

Quality and Quantity to meet your needs

CRB is one of the world's leading suppliers of pure, custom designed peptides. Using Fmoc-polyamide solid-phase synthesis and our economical continuous flow column technology, we'll make the peptide you need. At the purity you require. In the quantity you need. On any scale from milligram to kilogram.

Custom Synthesis of Peptides
Three reagent qualities to provide maximum economy in your peptide application.

1 Standard Reagent Grade – supplied with hplc profile and amino acid analysis.
2 Immunological Reagent Grade – for antibody production. Purity minimum 80%. Supplied with hplc profile, amino acid analysis and FAB mass spectrometric analysis result.
3 Bioassay Reagent (bR) Grade – for biological studies. Supplied by net peptide weight at a guaranteed purity in excess of 95% with complete analytical specification.

Large Scale Peptide Production
To meet the growing demands of the Pharmaceutical Industry, we have developed a new process to manufacture bulk peptides under GMP conditions. This NEW 'Continuous Flow Column Process' offers a rapid and economic method for large scale production.

CRB also offers:

Custom Conjugation of Peptides to Carrier Proteins

Custom Synthesis of High Purity Tritiated Peptides

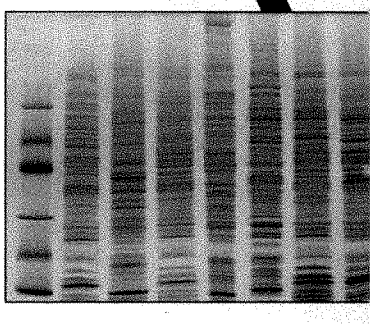
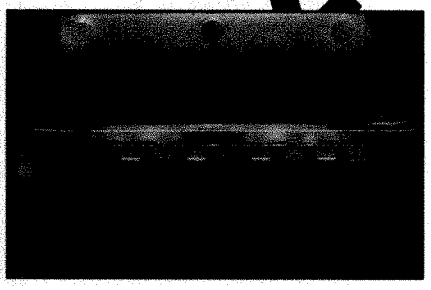
CRI5

1 9:00

Choose a precast gel from an extended range of 9 different PhastGel® media. Place gel and buffer strips in the separation unit.

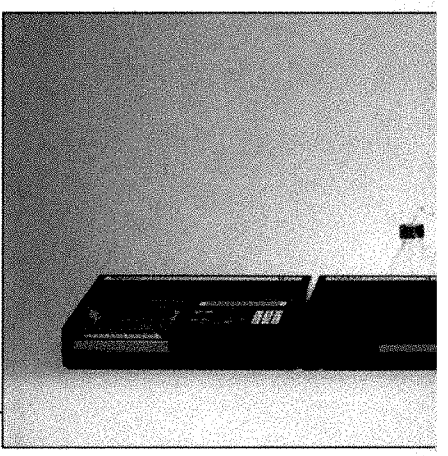




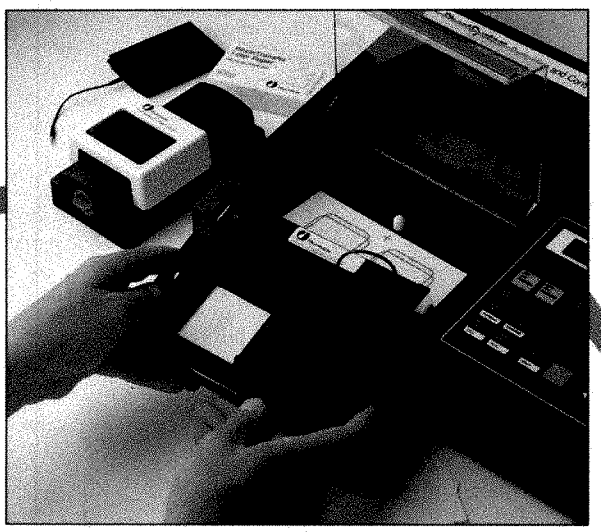
3 9:07

Program and run method.

4 9:37

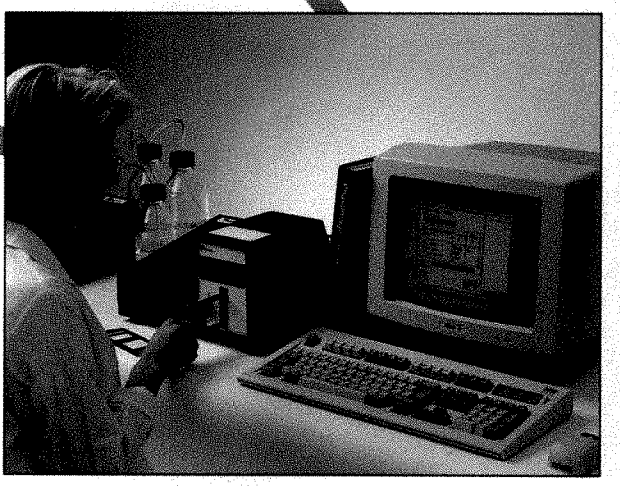


Develop gel automatically with silver or coomassie staining kits.

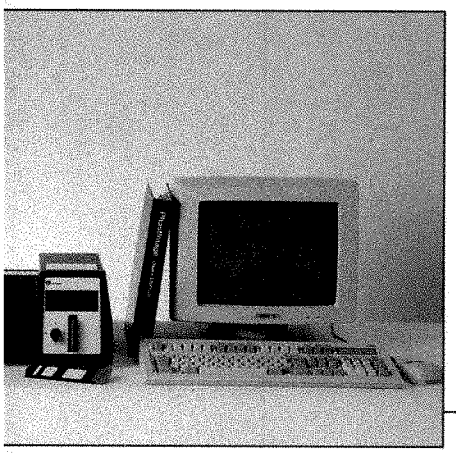


2 9:02

Load sample. Application is automated.



6 steps ahead



With PhastSystem™ you're at least 6 steps ahead of where you'd be with a conventional electrophoresis system. In the same time it takes to cast gels and prepare buffers for a conventional system, you could be ready to store results from a protein analysis run on PhastSystem. In less than an hour you can obtain accurate and reproducible results from any typical SDS – or native-PAGE separation. And an average isoelectric focusing run takes just 30 minutes.

5 9:37
Transfer proteins to a membrane in 15 minutes.

6 10:07
Scan and evaluate results.

Once you've gotten ahead, PhastSystem helps you to stay ahead. For fast, reproducible and economic transfer of PhastGel results, we now offer *PhastTransfer,*™ a new elecrophoretic blotting system. With the small format of PhastGel media, PhastTransfer uses less detection reagents than other elecrophoretic blotting units. And it consumes only 5 ml of buffer.

Then when you need to accurately and reproducibly evaluate results – whether they are in a PhastGel, an autoradiographic film or a PhastTransfer membrane – image analysis with the help of *PhastImage*™ is the final step. PhastImage is easy to operate and the same scanning procedure is used for one and two-dimensional gels.

After scanning, PhastImage determines band boundaries, defines the baseline, determines the optical densities of the bands or spots and integrates the volume. With the help of a personal computer for instrument control and data evaluation, PhastImage dramatically increases the information handling capability of PhastSystem.

PhastSystem — it's about time

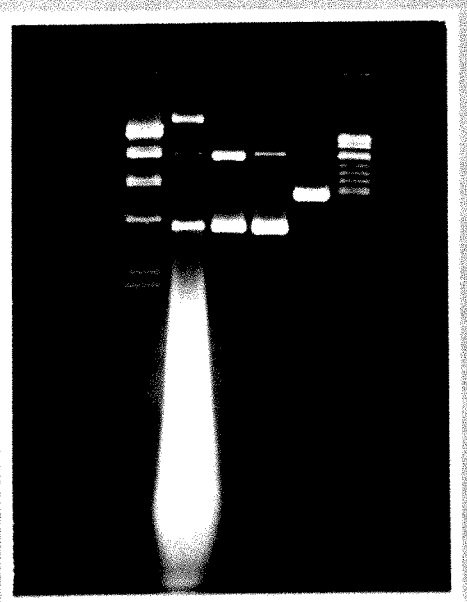
PLASMID ISOLATION THE BIO-RAD WAY. FAST, CLEAN, AND EASY.

Two new Bio-Rad purification technologies dramatically speed up and simplify the preparation of high purity recombinant DNA.

The HRLC® MA7 plasmid purification column



It's the high-resolution solution to time-consuming CsCl separations, providing a cost efficient and time saving means of isolating and purifying plasmid DNA. The unique, non-porous polymeric matrix allows you to:

- Purify up to 150 μg plasmid DNA from untreated cleared-cell lysates in under 1 hour, free of detectable RNA and chromosomal DNA
- Recover plasmid DNA exhibiting full activity as a substrate in enzymatic reactions.
- Purify deprotected synthetic oligonucleotides

Purification of 100 μg pUC 18 on the HRLC MA7 plasmid column (7.8 x 50 mm). Plasmid was prepared by alkaline lysis, with no RNase treatment.

New Prep-A-Gene™ DNA purification matrix

*Agarose gel (1%) electrophoresis of pBR322 DNA prepared by the cleared lysate method showing the efficiency of the Prep-A-Gene DNA purification matrix. **Lane 1:** Lambda DNA/Hind III digest; **Lane 2:** crude cell lysate prior to purification; **Lane 3:** pBR322 after banding on a CsCl gradient; **Lane 4:** pBR322 after purification with the Prep-A-Gene DNA purification matrix; **Lane 5:** BamH1 digested pBR322 from lane 4; **Lane 6:** ligated pBR322 from lane 5.*

A novel support developed at Bio-Rad for fast, easy, and inexpensive purification of plasmid DNA, restriction fragments, oligonucleotides, and other recombinant DNAs.

- Purify and concentrate DNA from agarose gels in minutes, free of impurities
- Purify and concentrate cloning quality DNA from mini- and midi-prep cell lysates, with no sample prep
- Desalt and concentrate DNA, as well as remove RNA, protein, organic solvents, SDS, and other impurities

For more details on either or both of these milestones in purification technology, call your Bio-Rad representative or contact us at 1-800-4BIO-RAD.

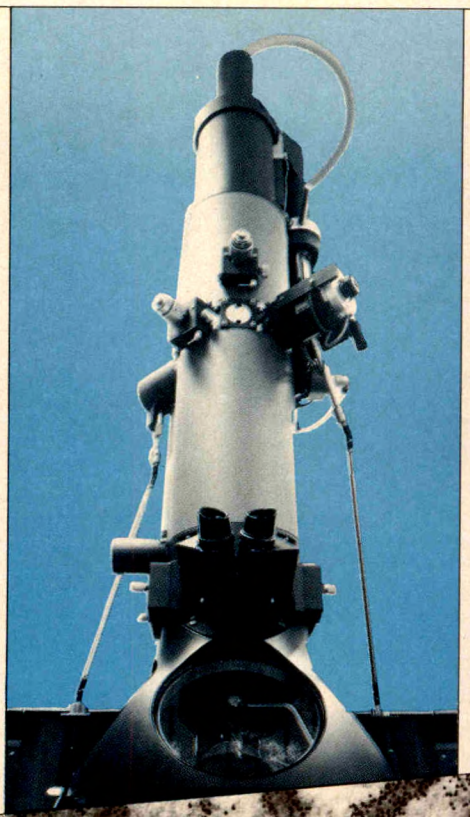
AuroProbe™ EM



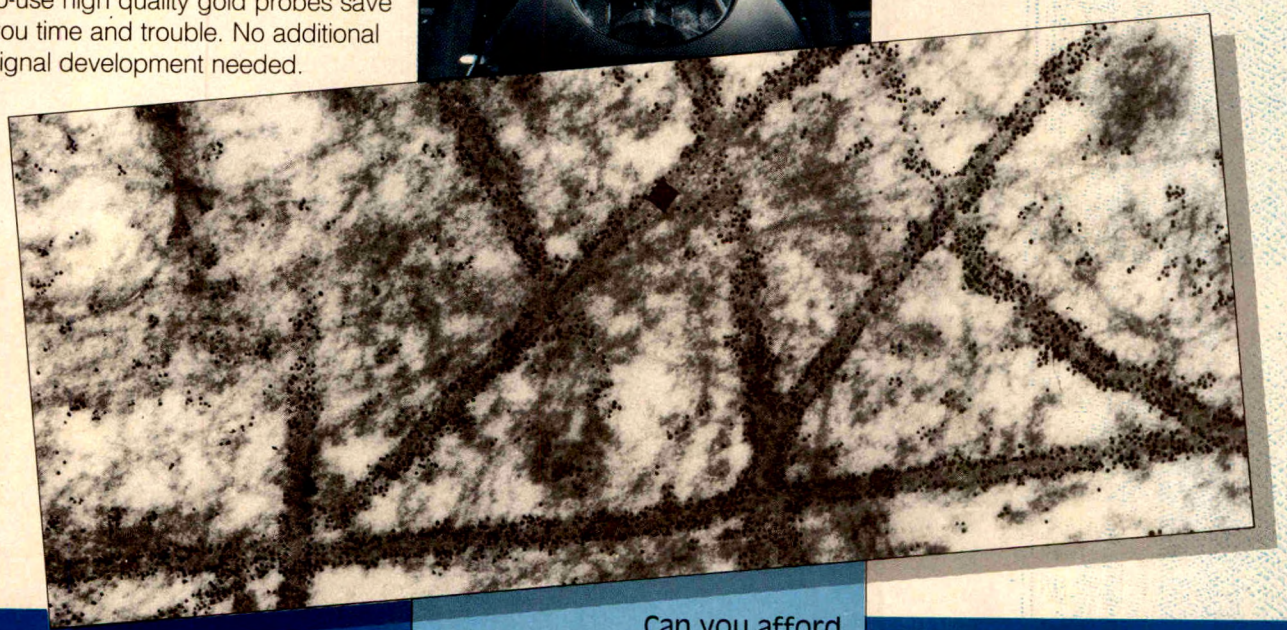
Clearly the label of choice in electron microscopy

Gold particles cannot be confounded with biological structures, since they are electron-dense and spherical. They provide quantifiable results and generate secondary and back-scattered electrons making the technique as useful in SEM as in TEM.

• **Double labelling:** Premium quality gold probes with narrow non-overlapping size distribution provide an excellent tool for double labelling.

• **Consistent quality:** Janssen Life Sciences Products guarantees batch-to-batch consistency. Each vial comes with a detailed morphometric quality analysis sheet.

• **Time and trouble saving:** Ready-to-use high quality gold probes save you time and trouble. No additional signal development needed.



• **Choice:** Available with secondary antibodies, protein A and streptavidin.

• **Stability:** Gold probes prepared by our own proprietary processing are stable for one year from the date of production.

• **No hazardous reagents:** The use of DAB and other possible carcinogens is completely avoided.

• **Detailed instructions:** Comprehensive instructions are supplied with each order.

Ultrastructural immunocytochemical localization of tubulin using specific tubulin antibody and AuroProbe EM GAR G5. Labelled microtubules are seen of a microtubule network of a PtK_2 interphase cell.

pioneers in gold probe technology

Auto-hydrolysis. The cornerstone of automated amino acid analysis.

Until now, "automated" amino acid analysis began with the hydrolyzed sample. The protein/peptide was hydrolyzed in a manual, multi-step procedure. The hydrolysate was extracted and transferred to the analyzer.

All this is changing with the Model 420A Amino Acid Analyzer, the first complete system to integrate hydrolysis, derivatization, chromatography and data analysis in one fully automated procedure.

Accurate, reproducible results become routine with automation and precise control of every step in the process. On-line auto-hydrolysis provides a solid foundation for higher sample recovery. Hands-off operation replaces manual sample handling, reducing the risk of contamination and sample loss during transfers. Throughput is higher. Once the first analysis is complete, the Model 420A reports the results on subsequent samples every 45 minutes.

Auto-hydrolysis. The systems approach to automated amino acid analysis requires it. Protein chemistry demands it. Contact Applied Biosystems for more information on the Model 420A today.

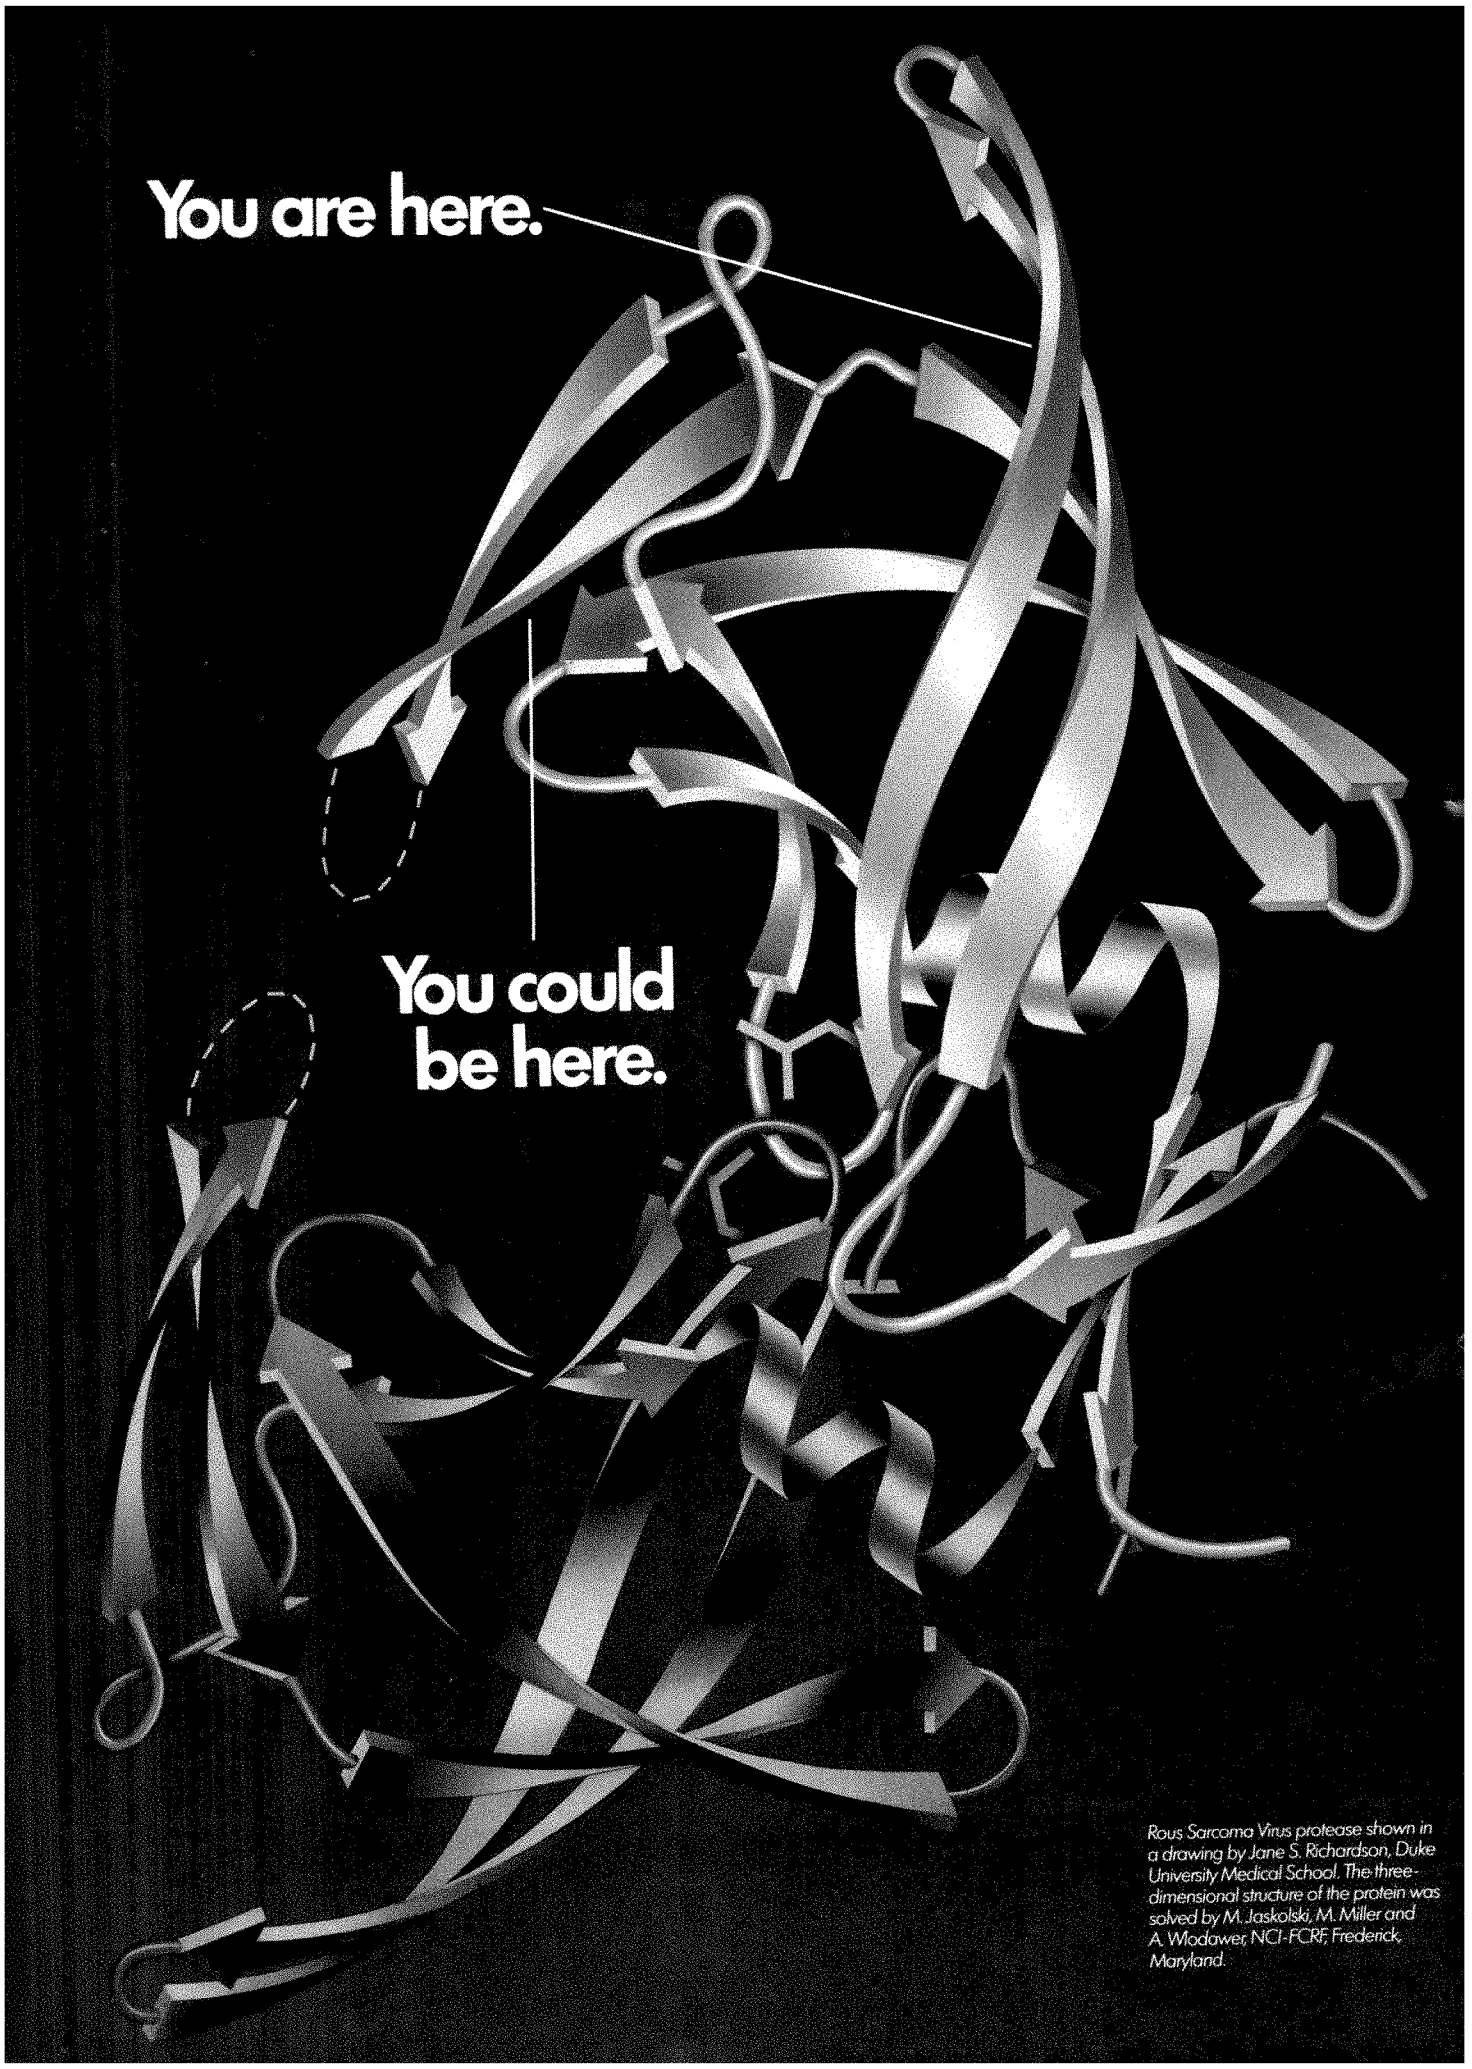
SCIENCE NEEDS SCIENCE

SINCE THE ADVENT OF THE HOURGLASS, SCIENTIFIC CREATIVITY HAS CONCENTRATED ON FINDING NEW WAYS OF SAVING TIME AND INCREASING RELIABILITY IN ALL FIELDS.

THE MOST RECENT SCIENTIFIC DISCOVERIES HAVE ALWAYS BEEN APPLIED TO DEVELOPING MORE ACCURATE AND RELIABLE RESEARCH TOOLS, WHICH IN TURN WILL PROMOTE SCIENTIFIC PROGRESS.

FOR OVER 30 YEARS, IN THE CONTINUING TRANSFER BETWEEN RESEARCH AND TECHNOLOGY BIO-RAD HAS BUILT ITS REPUTATION THROUGH:

- THE DESIGN, MANUFACTURE AND MARKETING OF INNOVATIVE SYSTEMS
- THE HIGH RELIABILITY OF ITS PRODUCTS ACKNOWLEDGED BY THE SCIENTIFIC COMMUNITY



BIO-RAD IS ACTIVE IN 6 MAJOR DISCIPLINES OF SCIENTIFIC AND MEDICAL RESEARCH:

- ◊ **FINE BIOCHEMICALS**
- ◊ **CHROMATOGRAPHY & ELECTROPHORESIS**
- ◊ **CLINICAL DIAGNOSTICS**
- ◊ **CONFOCAL LASER MICROSCOPY**
- ◊ **SEMICONDUCTOR MEASUREMENT SYSTEMS**
- ◊ **FOURIER TRANSFORM INFRARED SPECTROMETERS**

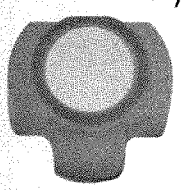
JPSA

Rous Sarcoma Virus protease shown in a drawing by Jane S. Richardson, Duke University Medical School. The three-dimensional structure of the protein was solved by M. Jaskolski, M. Miller and A. Wlodawer, NCI-FCRF, Frederick, Maryland.

Introducing new Covalent Sequencing technology from MilliGen/Biosearch.



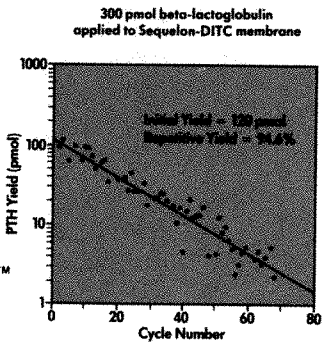
Every protein investigator knows, you can sequence more residues by covalently attaching protein samples than by simple adsorption.

Covalently immobilizing a protein or peptide allows you to use polar solvents to wash away excess reagent and reaction by-products, providing cleaner chromatograms, enhanced sensitivity and extended sequence runs.

Unfortunately, finding something to attach the protein to has been a nightmare. Early methods used glass beads. But handling them required too much finesse and took too much time.

New attachment chemistry makes sample preparation fast and easy. At MilliGen/Biosearch, we've developed a way to covalently attach protein samples to a DITC derivatized PVDF membrane, eliminating sample wash-out, and allowing researchers to use smaller amounts of material.

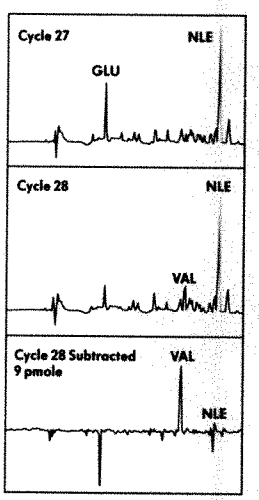
For peptides, we modify a Millipore PVDF membrane with aryl amine. This functionalization allows for covalent linkage with the C-terminal and side-chain carboxyl groups.



Covalent attachment of proteins and peptides to special Sequelon™ membranes prevents extractive losses during sequencing. (Photo is 1.5 times actual size.)

Electroblotted proteins are bound by our unique SequeNet™ process. With this new method, a polyamine polymer and protein amine groups are cross-linked with DITC. The resulting thin polymer network conforms closely to the membrane surface, covalently entrapping the molecule for sequencing.

In any case, the attachment protocol requires just 15-20 minutes of simple benchtop chemistry. And, if you're performing electroblot purification, the SequeNet process lets you sequence directly from Millipore's Immobilon™–P membrane.

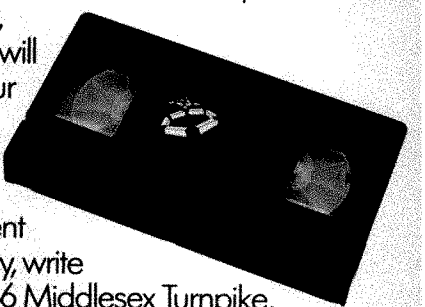


Taking the "hard" out of hardware. Everything is automated, from sequencing through sequence printout. On-line HPLC provides PTH amino acid analysis with 100% injection of PTH derivatives. PTH-Maxima™ software automatically compares cycles, eliminating carry-over effects and system artifacts. So you get a difference trace with easily identifiable peaks for fast, accurate interpretation.

From a sample of a few hundred picomoles, Covalent Sequencing makes it possible to obtain sequence information beyond 60 cycles, with repetitive yields around 95%.

MilliGen/Biosearch ProSequencer™ systems use conventional Edman degradation chemistry. But they're also compatible with emerging multi-reagent protocols, and will be especially suited for use with new detection methods now in development.

You have a question? We have the answer. When you call us with a question, you won't be bounced from person to person looking for an answer. You'll talk directly with some of the most knowledgeable people in the business.



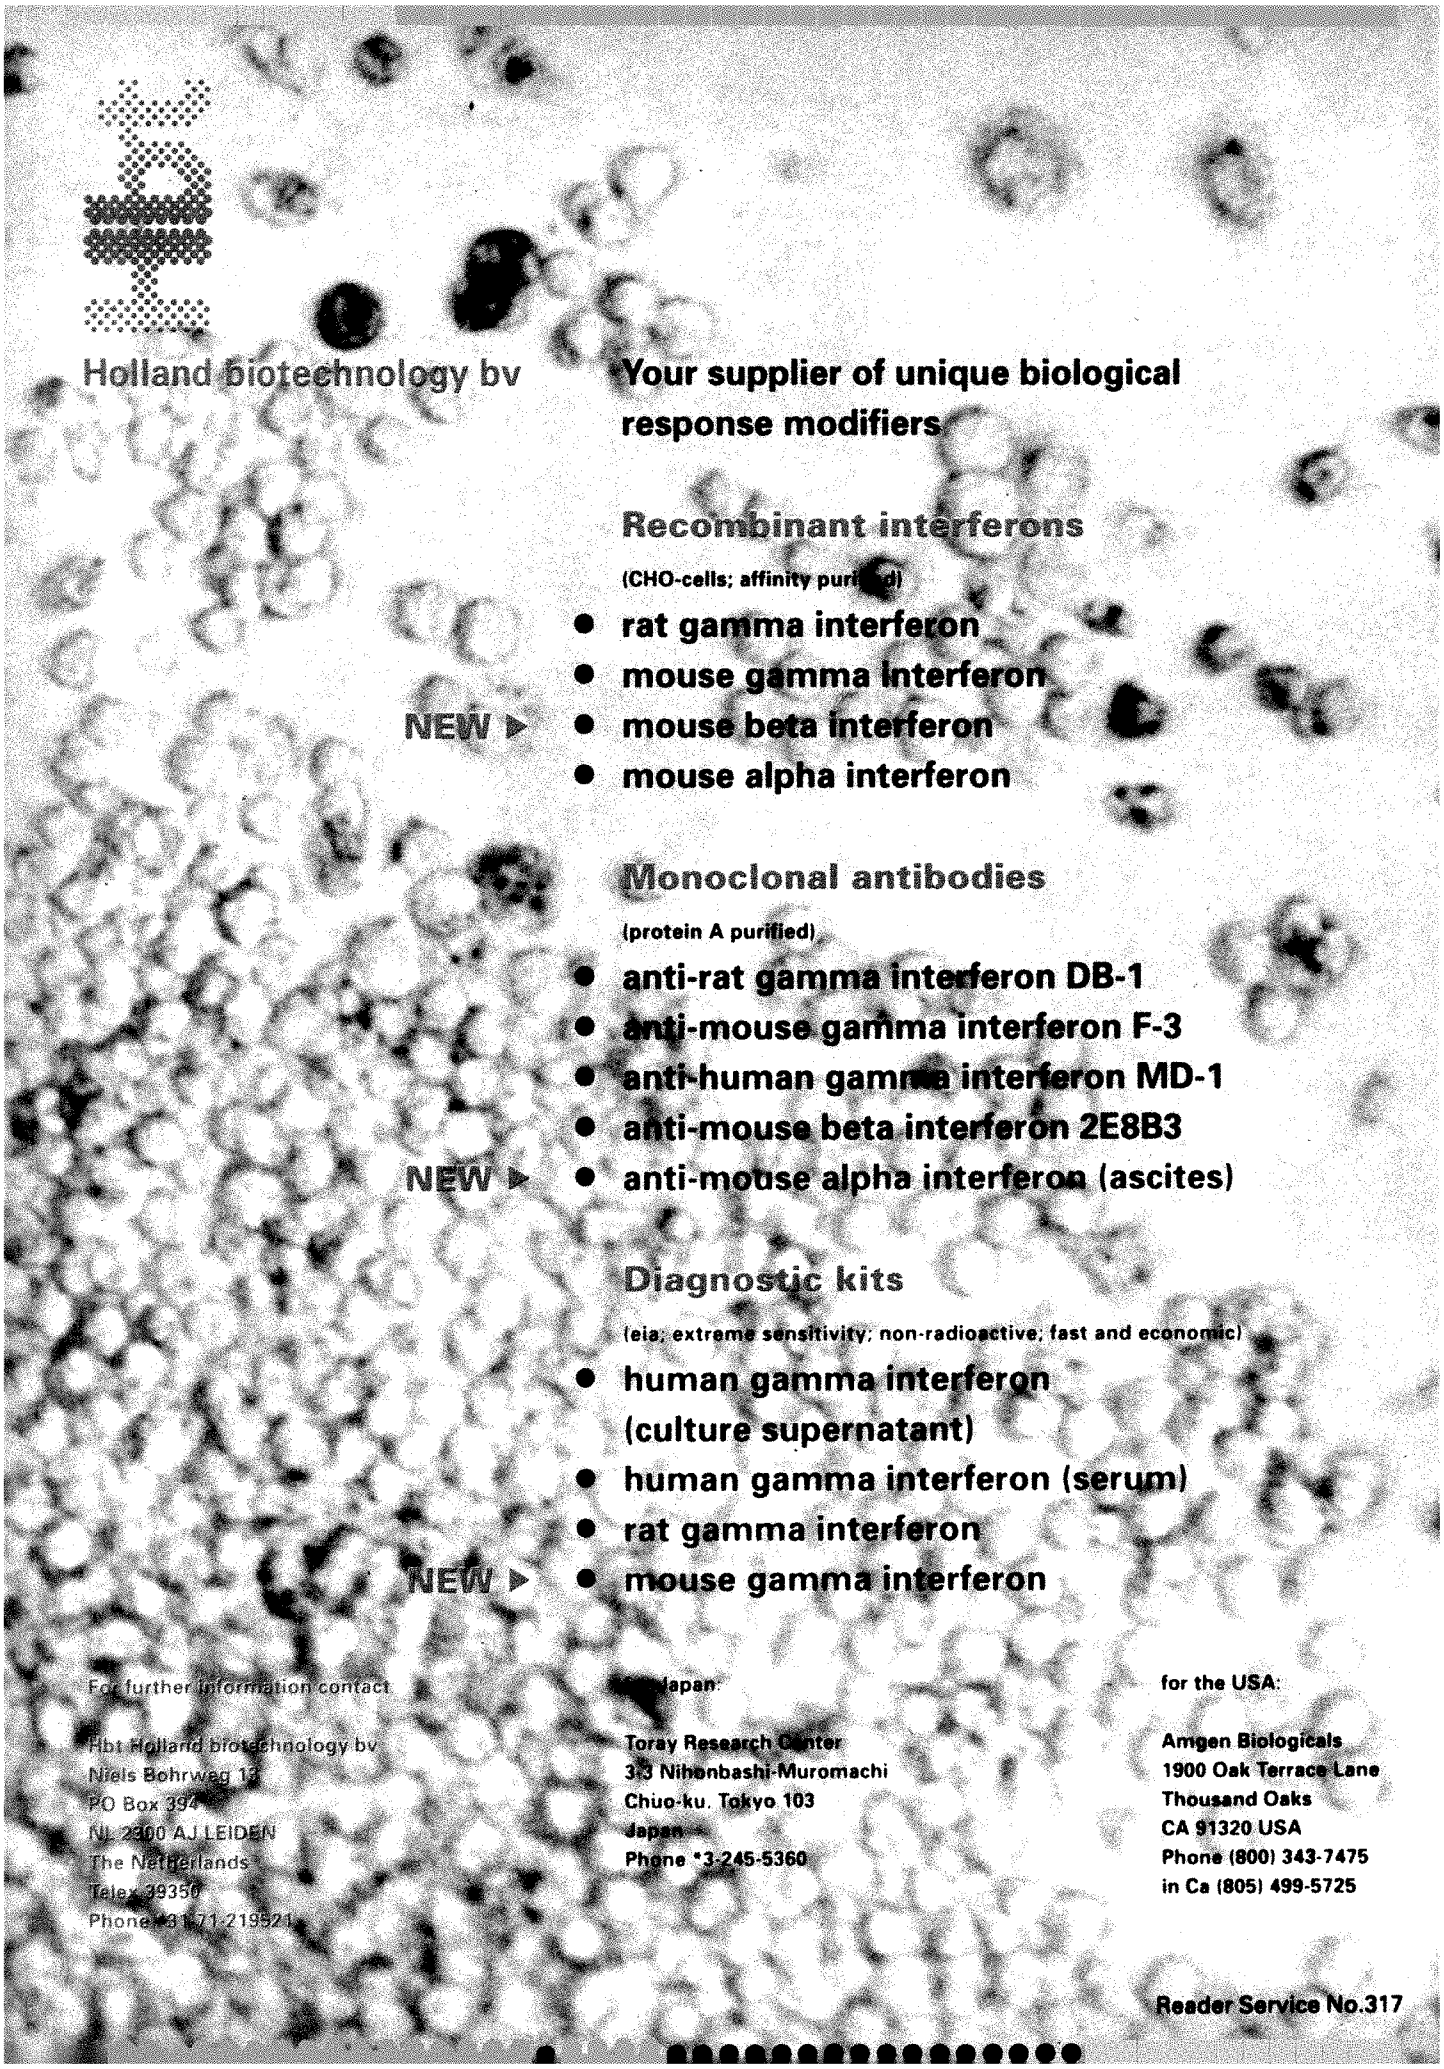
Special software automatically subtracts previous runs from new ones, producing clear, accurate readings.

Our technical support team is staffed by men and women who've run core facilities, and others who've spent their lives working with proteins. At places like Harvard, The University of Leeds and The Howard Hughes Institute.

And, on the off chance we can't give you an answer on the spot, you don't have to call us back—we'll call you. Usually, within the hour.

Combined effort makes it possible. By pooling our expertise in bioinstrumentation with the knowledge and resources of Millipore and Waters, we solved a problem that's plagued researchers for nearly 25 years. And it couldn't have come at a better time.

Many protein chemists believe adsorptive technology has come as far as it can—that its potential is "maxed out." But now, Covalent Sequencing will help take you, and your research, further.



For more information, including a free video detailing Covalent Sequencing technology, write MilliGen/Biosearch, 186 Middlesex Turnpike, Burlington, MA 01803. Or call 800-872-0071 (in MA: 617-229-2870). We can also be reached by calling France: 30.45.70.00; Japan: 471-7191; U.K.: 923 816375; or W. Germany: (06196) 494-0.

We promise if you stick with us, you'll go places.

TECHNE

FULLY PROGRAMMABLE DRI-BLOCK® TEMPERATURE CYCLER PHC-2

This latest programmable Dri-Block® temperature cycler PHC-2 has a powerful microprocessor programming capability yet is designed for simplicity of operation. It is now possible to link programmes, hold temperatures for long periods choose four ramp rates up and down and recall temperatures and times from the PHC-2 memory. Two models are available for use with either 0.5 ml or 1.5 ml microcentrifuge tubes.

- Temperature range 0°C–99°C
- Fast temperature change
- Wide and variable number of segments, programmes and cycles – limited only by memory capacity.
- Four user selectable up/down ramp rates
- 99 hour maximum hold time
- Remote sensor in dummy tube to read sample temperature and initiate programme timing.
- Block uniformity 3°C
- RS232 outlet/centronics printer output
- 54×0.5 ml or 24×1.5 ml microcentrifuge tubes
- Water cooled with separate connection for end of programme below ambient cooling
- Temperatures and times held in memory for recall to screen or printer

PHC–1

For less sophisticated programming requirements the alternative model PHC-1 is a simple to use heat/cool unit providing a repeatable cycle of up to three independent temperatures and dwell times. A standard aluminium block will accept up to 54×0.5 ml capped microcentrifuge tubes.

WHERE THE KNOWS COUNT

We can offer you the **most complete line of Endothelins** because we are *always a nose ahead* of the competition.

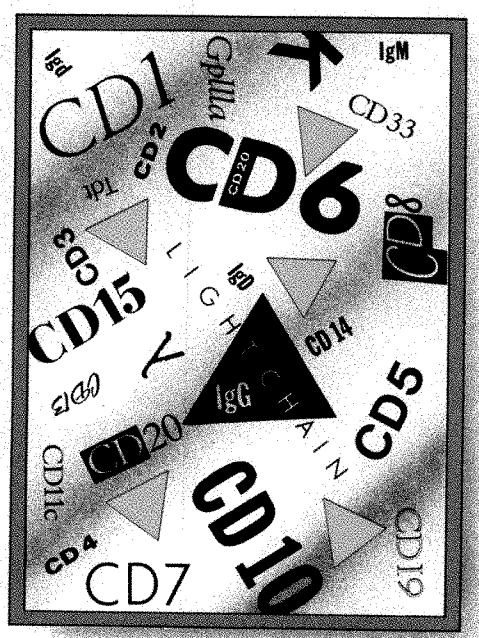
Call your best source for *Endothelins:*

- *human Big ET (1-38)*
- *porcine Big ET (1-39)*
- *human, porcine ET-1*
- *human ET-2*
- *human, rat ET-3*
- *human Big ET (22-38)*
- *porcine Big ET (22-39)*
- *mouse ET (V.I.C.)*

All of them on stock in practically unlimited amount.

We are your best source for *FAST Custom Peptides.*

- APC offers you *solid 98%* quality at the best prices.
- APC delivers custom peptides in *3-4 weeks.*
- APC offers you a *free quote* for any custom peptide.



Call us TODAY
Choose the best in peptides.
You can bet on us!

LEUCOCYTE TYPING

The Complete Picture

VERItype™

Now, for the first time, the full range of high quality, high affinity CD nomenclature antibodies from a single source.
VERItype™ from Sera-Lab. Fully tested in routinely used assay techniques, *VERItype*™ monoclonal antibodies to human leucocytes antigens enable you to have complete confidence in your results. And with maximum convenience. The range of matched reagents comes in kits and individual vials (25 and 100 test sizes) complete with antibody profile and methodology booklet.

VERItype™ – *comprehensive, convenient . . . used with confidence.*
SEND FOR FURTHER INFORMATION NOW.

WANTED
BY
COSMO BIO CO., LTD.
MANUFACTURERS

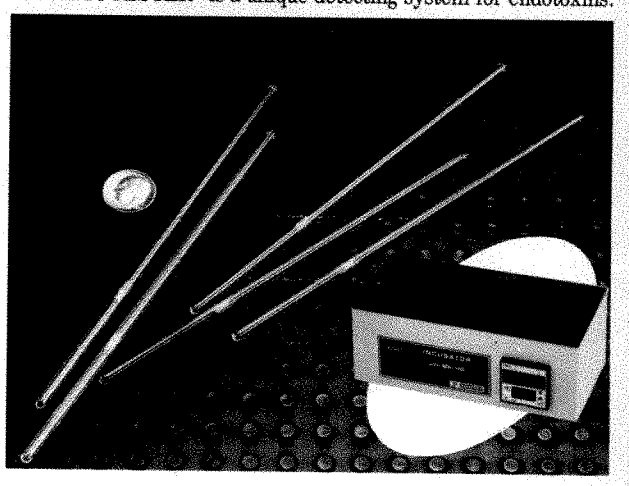
YOU are a manufacturer in the fields of;
(1) Research Reagents (Immunology, Genetic Engineering, Tissue Culture...)
(2) Clinical Diagnostics
(3) Laboratory Instrumentation

WITH quality products

AND are committed to entering the Japanese market

WE are backed by the experience of over a decade in both distribution and the provision of related technical assistance of the highest order

WITH the backing (100%-owned) of the third-largest integrated oil company in Japan, COSMO OIL CO., LTD.



AND are committed to future success with you

Contact;
COSMO BIO CO., LTD.
Mr M. Shimizu and Mr N. Yamaguchi

LIMUTESTER®

The LIMUTESTER® is a unique detecting system for endotoxins.

CHARACTERISTICS :

* Simple handling – can detect endotoxins anywhere without preparing special tools.
* Excellent reproducibility and sensitivity (0.06–0.10 ng/ml).
* Low cost.

A special INCUBATOR for LIMUTESTER® is also available.

For more information contact : **Reader Service No.11**

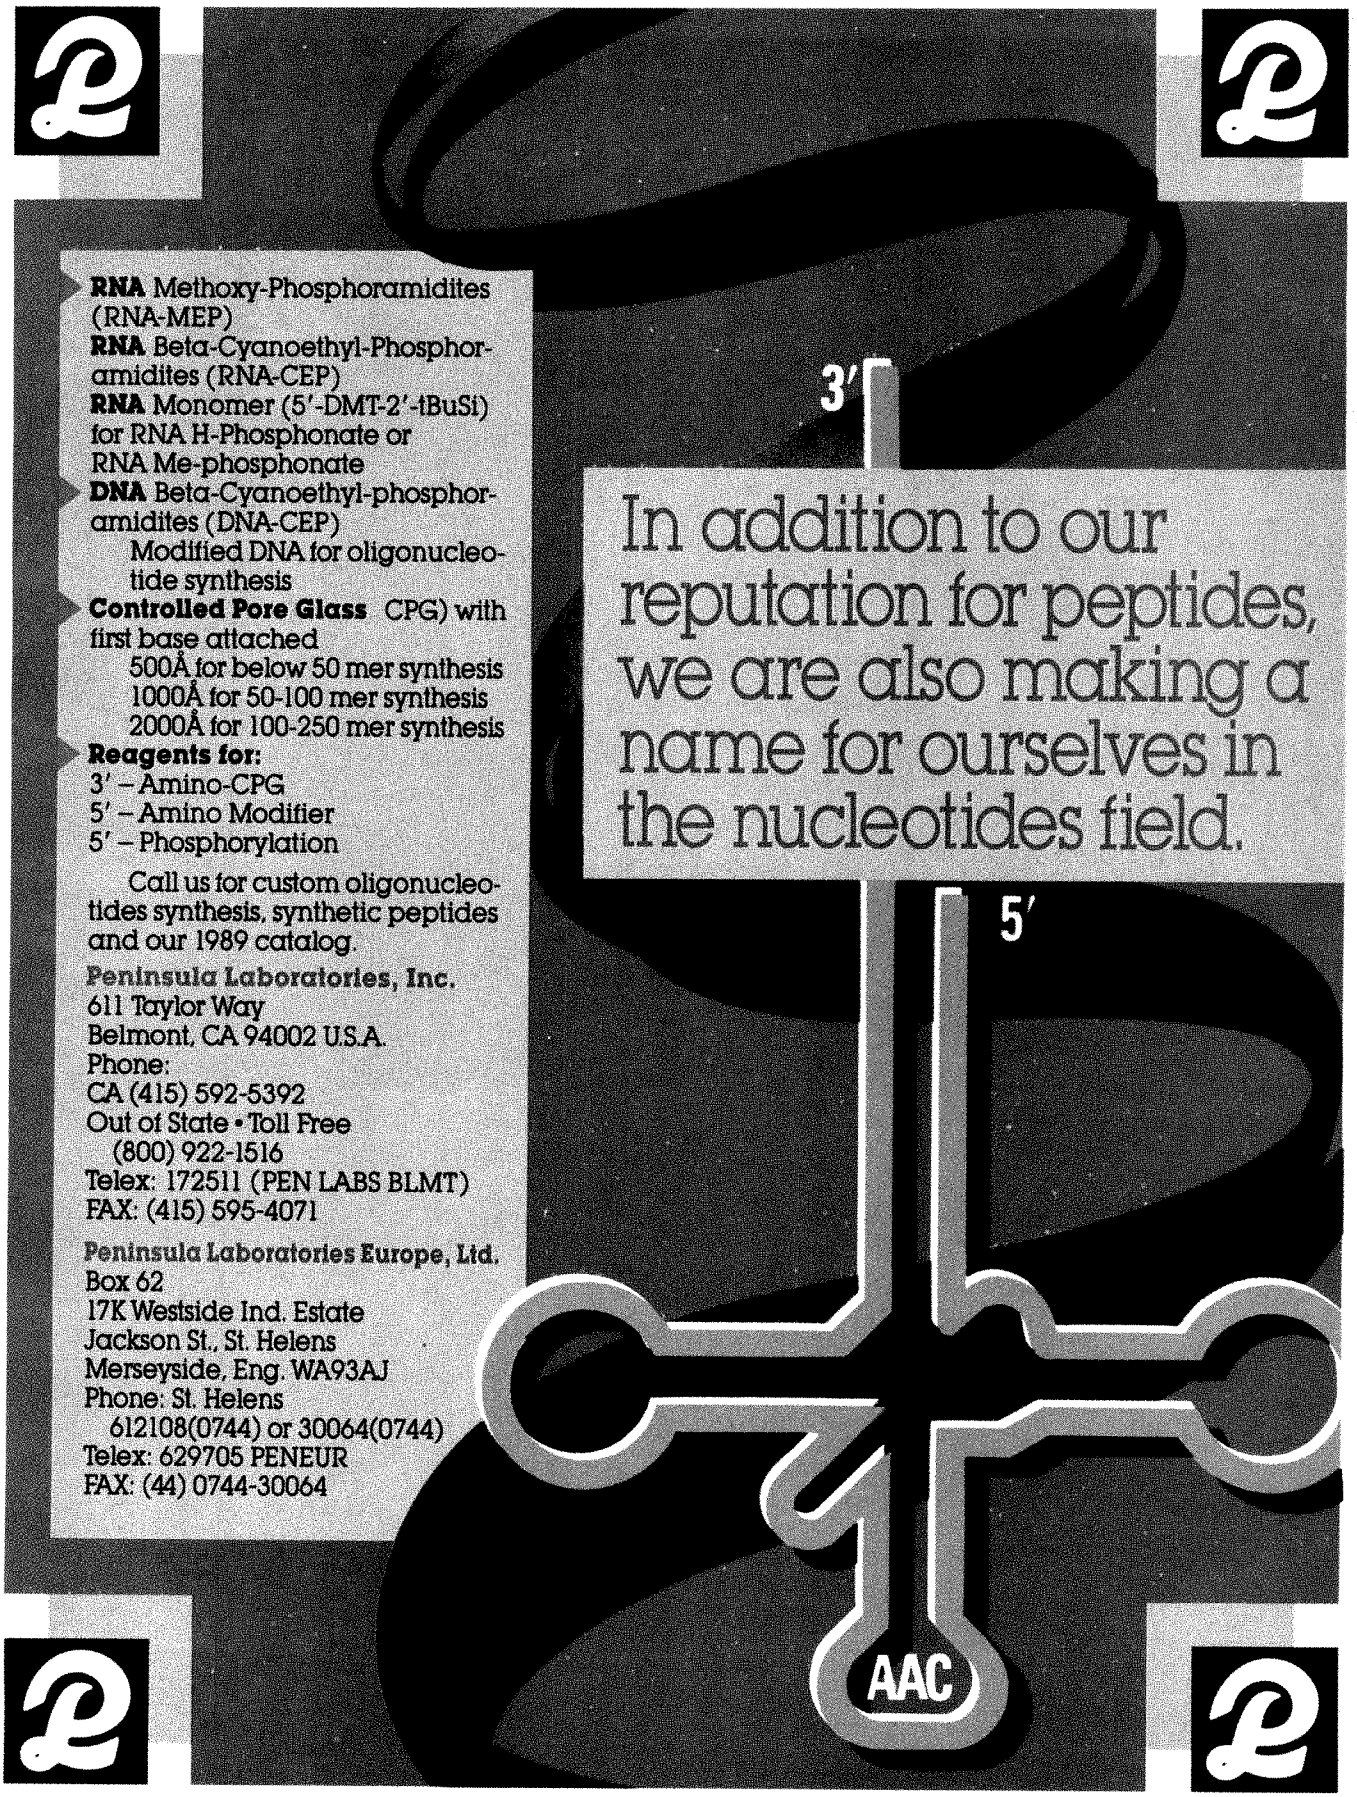
Tools For The Molecular Biologist 1989/1990

Oncogene Analysis by GeneAmp™ PCR†

BE THE FIRST TO GET THE FIRST

Call today for your 1989/1990 CLONTECH catalog:

Tools for the Molecular Biologist



- **The first** with **CLIK™** immunoscreening kits
- **The first** with custom DNA library construction
- **The first** with cDNA and genomic libraries —Libraries are our Turf!
- **The first** with poly(A)⁺ RNAs and genomic DNAs
- **The first** with custom gene expression blots and 50-900kb lambda markers
- **The first** with **CHROMO-BLOT™** chromosomal markers
- **The first** with longest arm Biotin-21-dUTP
- **The first** with **AminoModifiers™** and 3' **Amine-ON CPG™**
- **The first** with custom gene isolation —the **GENE-TEAM™**
- **The first** with **DI-HYBRIDIZER™** gel wafers for direct gel hybridization
- **The first** with **ZOO-BLOTS™**
- **The first** with **MEGA-Rose™** for megabase DNA separation
- **The first** with **ONCO-LYZER™ GeneAmp™ PCR†** kits for research Oncogene Screening

The DNA DIPSTICK™

Makes Quantification Fast & Simple!

Invitrogen Introduces a Fast, Simple, Non Radioactive Method For Quantification of Nucleic Acids with The DNA DIPSTICK.

- Quantitates Nucleic Acids at Concentrations as Low as one Nanogram per Microliter

Quantification Doesn't Get any Easier

- Provides a Permanent Record of Results
- Is More Consistent Than Conventional Techniques
- Requires no Special Equipment for Fast Inexpensive Results
- Ideal for Quantification of single or double stranded DNA, RNA or oligonucleotides

Now you can have fast, accurate nucleic acid measurements which are critical for PCR Amplification, Subcloning, DNA sequencing, and cDNA or Genomic DNA Library Construction.

Because time and accuracy are very important in today's rapidly changing world, Invitrogen is committed to providing DNA Technology that is as advanced as it is simple.

To order, ask for catalog #K5632-01.

YOUR SINGLE SOURCE FOR SCORES OF ANTIBODIES.

Monoclonal antibodies to leukocytes.

Immunotech and its U.S. subsidiary AMAC offer a complete line of over 60 reagents for leukocyte analysis, from unique specificities to routine markers. Some are specificities that are very difficult to obtain, such as CD23, CD32, LFA I, ICAM, intestinal lymphocyte, and FcIgE receptor. Our IOTEST® panel of reagents is designed specifically for use with flow cytometry. We also have a full line of routine markers. All are well-characterized and convenient to use. For more information, call or write the monoclonal antibody specialists.

The reasons for making your own peptides are right in front of you.

f your research can't wait or weeks while you wait for peptides, take a look at the new Excell™ Automated Peptide Synthesizer from MilliGen/Biosearch.

With the Excell system, you don't have to be an expert to synthesize high-quality, biologically active peptides. Simply enter your sequence, add prepack-aged reagents, amino acid cartridges and reaction column, push "Start Synthesis," and walk away.

Using proven Fmoc/BOP + HOBt protocols (no HF), Excell achieves yields > 99% and cycle times < 1 hour.

Excell system Expert™ software recommends the best protocol for your sequence, automatically assigns coupling strategies, calculates reagent amounts, and verifies the sequence. Self-prompting menus guide you through each step, while a real-time synthesis report documents them.

And since it's priced within the reach of most facilities, there's no reason to wait another day. For more information call 800-872-0071; in MA, 617-229-2870.

RE PROUD OF OUR PACKAGING.

LOOK LIKE MUCH TO YOU BUT... A USED BOX TO YOU MEANS 20,000 FEWER TO A LANDFILL.

England Biolabs, Inc., we are concerned about the environment and want to promote sound ecological practices. too, to take a small but important step. For 14 years we have asked customers to "recycle" our styrofoam sing a box as many as 10 times, we keep more than 20,000 styrofoam boxes, per year, out of landfills and Stacked solid, that's the volume of a livable house!)

make return easier, all NEB boxes are delivered with a return postage paid sticker. Just tape the box closed the U.S. mail — ice packs and all. The cost of recovering our box through the mail is actually greater than new box, but the savings are environmental. So, thanks for sending the boxes back.

THE SPECIALISTS IN RESTRICTION ENDONUCLEASES

Now, a system for assaying gene regulatory elements

Send in the CAT

TLC analysis of CAT activity in extracts prepared from cells transfected with the following plasmids:

1. pCAT™-Basic
2. pCAT™-Enhancer
3. pCAT™-Promoter
4. pCAT™-Control

Introducing the new CAT reporter systems for the direct assay of your gene regulatory elements by measuring chloramphenicol acetyltransferase (CAT) activity.

CAT Assay System

- Simple Assays—buffer and cofactor provided
- Choice—TLC or liquid scintillation counting (LSC) analysis
- LSC Analysis
  - Quick—30 minutes assay
  - Sensitive and quantitative—detects broad range of enzyme activity (3 orders of magnitude)

Complete Set of Plasmids

- No Background—low endogenous CAT expression
- Identical Plasmid Contexts—related plasmid set allow quantitative comparisons
- Test Your Gene Regulatory Elements as a Unit or Sep
  - pCAT™-Basic Plasmid—no SV40 promoter or enha
  - pCAT™-Enhancer Plasmid—only the SV40 enhance present; test your promoter strength
  - pCAT™-Promoter Plasmid—only the SV40 promote present; test your enhancer activity
  - pCAT™-Control Plasmid—provides high levels of C activity; control for transfection efficiencies and fo comparing promoter and enhancer strengths

DH ESSENTIAL SCIENCE • BDH ESSENTIAL SCIENCE • BDH ESSENTIAL SCIENC

Everything you want – without the things you don't want.

A NEW RANGE OF REAGENTS, CREATED FOR MOLECULAR BIOLOGISTS.

Why take risks.

By taking care to only use reagents that are free of contaminating DNase, RNase and Protease enzymes you'll have an additional safeguard for your work and its integrity.

Vital results can so easily be compromised and your valuable time and research efforts wasted.

You want results. You want them fast. So think carefully when it comes to selecting reagents; this is an area where you shouldn't be taking chances.

The new range of BDH molecular biology grade reagents meets stringent requirements, assuring freedom from DNase, RNase and Protease enzymes.

Special test methods have been developed in the BDH Research Department at Poole, Dorset.

The high sensitivity of these new BDH tests and our manufacturing skills now make a major contribution to progress through provision of a significant and expanding range of reagents, all of which will be found of value in modern molecular biology work.

New reagents and testing methods are fully outlined for you in a special Product Information Sheet which is available now on request.

So please contact the address below for all the information you need.

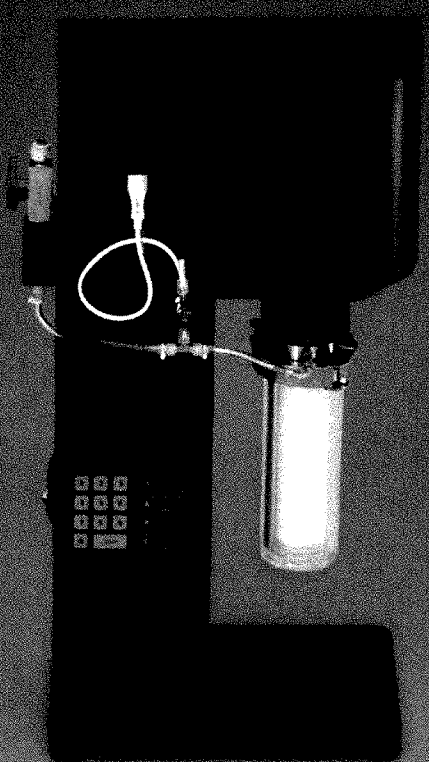
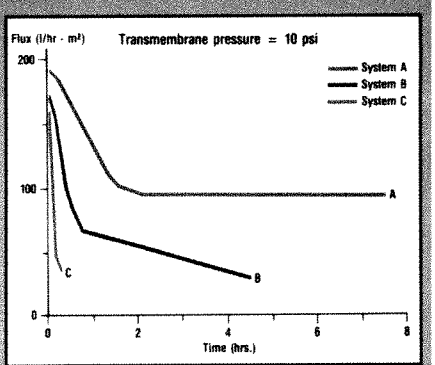
A Revolutionary Advance in Laboratory Separations



The newest, most efficient separation technology available today. The Benchmark System easily and effectively handles a wide range of biological separations, from crude upstream broths, to downstream protein purifications. All with one, high performance membrane - based system. Now, you can expect better results with:

- Higher product recoveries
- Faster, more stable flow rates
- Simple and convenient operating features
- A single system for multiple step separations

An advanced system that surpasses conventional separation methods. The Benchmark System represents a new approach that combines unique UltraFilic™ Membranes with innovative rotary separation technology. It will let you effectively replace multiple separation technologies in your lab such as: centrifugation, chemical precipitation and dialysis, as well as stirred cell, tangential flow and dead-end filtration. Use the system for concentration, clarification, diafiltration and fractionation of soluble and insoluble proteins and other complex biomolecules, or for cell harvesting and washing.



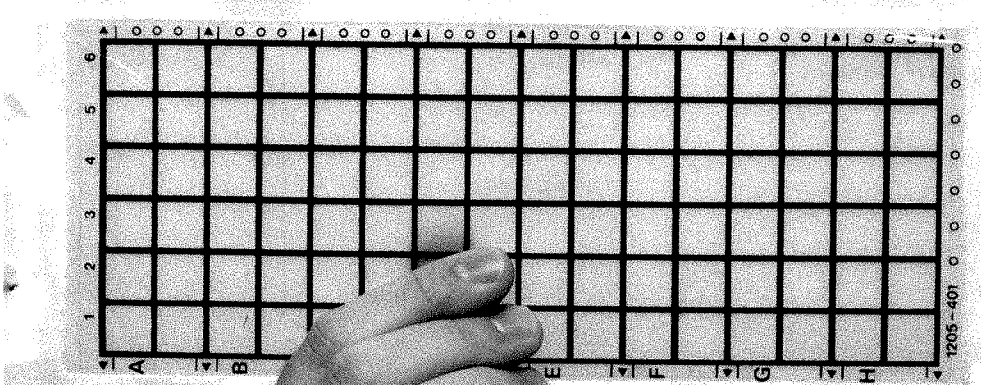
Meet all the critical demands for today's laboratory separations. Benchmark utilizes the most hydrophilic membranes and advanced fluid dynamics available to minimize non-specific binding and membrane fouling providing the highest possible product recovery. And, Benchmark's gentle and efficient processing provides a low shear environment for better results in processing mammalian cells and other shear sensitive products.

Easily set-up, and even easier to use. Benchmark is available in several configurations for processing volumes ranging from 10 ml to 10 liters and greater. The system can be set up in minutes and all key operating parameters are easily controlled and monitored from the system's digital display. Plug-on membrane cartridges enable easy membrane changeover for rapidly performing multiple step separations.

Higher, more stable flow rates. The Benchmark System's non-fouling capabilities allow it to consistently deliver flux rates 2 to 5 times higher than other membrane filtration systems. You can also achieve higher product concentrations faster than ever before, stable flow rates are maintained, even with extremely high protein or cell concentrations. Remarkably durable, UltraFilic Membranes withstand repeated cleaning - even autoclaving - to provide unsurpassed flux recovery for excellent separation reproducibility.

Comparison of flux over time with Benchmark rotary system (A), using either a 0.45 µm polysulfone membrane or a 100K UltraFilic Membrane, vs. tangential flow devices (New Brunswick TM -100 (B) and Millipore Pellicon® (C), both using 0.2 µm PVDF membranes) for the concentration of a 1% (dry weight) yeast broth.

Benchmark maintained stable flux for more than 7 hours and achieved a 25 fold concentration. Neither tangential flow device was able to achieve a stable flux and both clogged before completion of the run.



Revolutionize your laboratory; system prices start at $7,500.00. The Benchmark System is sold and supported by MEMBREX, a new and growing force in separations technology. A fully staffed applications lab is continuously developing and supporting Benchmark applications. For more information, circle Reader Service No. **250**

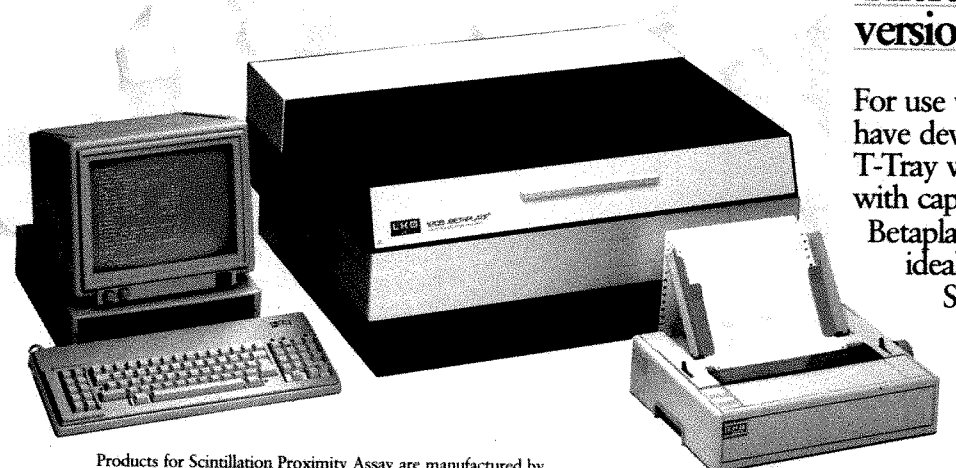
Before you drown in vials...



With the Betaplate liquid scintillation counter you can handle 96 samples as easily as one

The 1205 Betaplate™ liquid scintillation counter allows savings in time, work and c sumables. For all application involving samples which ha to be harvested onto filterm or spotted onto membranes you no longer need to labo with vials. You don't have t punch out and place every single sample in a vial, label add cocktail, and load it int a rack. Instead, to eliminate this work, you can load the whole filtermat with up to 9 samples into the Betaplate counter.

There's now an SP version of Betaplate

For use with Betaplate, we have developed a special T-Tray with 96 wells each with capacity 400μL.

Betaplate with T-Tray is ideal for homogeneous Scintillation Proximity Assay (SPA) as well as many other potential applications.

The high throughput Betaplate™ has six detectors and total capacity 20 counting casettes or 1920 samples

Products for Scintillation Proximity Assay are manufactured by Amersham International plc.

Stay on top with the latest developments in IMMUNOLOGY

P. Ivanyi, Amsterdam (Ed.)

Realm of Tolerance

1989. XIX, 314 pp. 72 figs. Hardcover
DM 64,- ISBN 3-540-51056-7

In this book dedicated to the memory of Milan Hašek, former director of the Prague Institute of Experimental Biology and Genetics, the contributions cover topics ranging from tolerance, immune network and immunogenetics to the immunology of bacterial and viral infections.

P. Ivanyi, Amsterdam (Ed.)

MHC + X

Complex Formation and Antibody Induction

1988. XXII, 247 pp. 63 figs. 47 tabs. Hardcover DM 165,- ISBN 3-540-50247-5

This is the first book devoted completely to Complex Formation by Histocompatibility Antigens (MHC+X). The contributions stem from a broad panel of researchers from various countries, their views show the very different aspects of MHC function.

A. L. Notkins, Bethesda, MD;
M. B. A. Oldstone, La Jolla, CA (Eds.)

Concepts in Viral Pathogenesis III

1989 XIX, 389 pp. 60 figs. Hardcover
DM 148,- ISBN 3-540-96974-8

Up-to-date information in this volume contains contributions by leading authorities on structure-function relationships, gene regulation, cell biology of viral infections, transgenic mice, expression of viral genes, retroviruses, and evolving concepts in viral diseases.

K. Rother, University of Heidelberg;
G. O. Till, University of Michigan (Eds.)

The Complement System

1988. XV, 535 pp 70 figs. Hardcover
DM 180,- ISBN 3-540-18205-5

The serum complement system plays an essential part in understanding inflammation processes and body defense mechanisms. This excellent book offers the only broad coverage of the field and integrates in separate chapters the physiochemical and biological aspects of the complement system

S. Ferrone, Valhalla, NY (Ed.)

Human Melanoma

From Basic Research to Clinical Application

1989. Approx. 500 pp. 123 figs. Hardcover
DM 348,- ISBN 3-540-50814-7

This is a ready source of information on melanoma, spanning from basic research to clinical investigations. Special emphasis is placed on immunology and molecular biology, and results derived from the application of biotechnology to melanoma are reviewed

B. Dupont, Cornell University (Ed.)

Immunobiology of HLA

Part 1: Histocompatibility Testing 1987

Part 2: Immunogenetics and Histocompatibility

1989. XLVIII, 1701 pp. 550 figs. (in two vols., not available separately). Hardcover DM 690,- ISBN 3-540-96826-1

This excellent two-volume set is a comprehensive summary of the most recent findings in HLA research, drawn from the results of the Tenth International Histocompatibility Workshop and Conference.

D. J. Bibel, Oakland, CA

Milestones in Immunology

A Historical Exploration

With a Foreword by A. M Silverstein

1988. XIX, 330 pp Hardcover DM 64,-
ISBN 3-540-19345-6

This unique book breaks the traditional boundaries of history in providing the first overview of the history of immunology from its origin to the exciting developments of recent years, going beyond the usually described development of vaccines

The State-of-the-Art PCR Laboratory Manual!

PCR Protocols

A Guide to Methods and Applications

edited by

Michael A. Innis, David H. Gelfand, John J. Sninsky, and Thomas J. White

Designed for use at the laboratory bench, this is the most comprehensive manual on PCR available today. Over 50 chapters provide precise instructions on procedures, with advice on primer design. All of the techniques described, from amplification and direct sequencing of genomic DNA through cDNA cloning and quantitation of mRNA, are tested, current, and supplemented with helpful notes and illustrations.

You'll also learn how to:

- ◆ Optimize novel applications
- ◆ Avoid many cumbersome molecular biological techniques
- ◆ Set up the laboratory to avoid contamination

Affordable, well written, and self-contained—all biological scientists using PCR will find this comb-bound volume indispensable.

CONTENTS (Section Headings): Part I: Basic Methodology. Part II: Research Applications. Part III: Genetics and Evolution. Part IV: Diagnostics and Forensics. Part V: Instrumentation and Supplies.

Comb bound: $39.95 (tentative)/ISBN: 0-12-372181-4
Casebound: $69.50 (tentative)/ISBN: 0-12-372180-6

Stirred but not damaged.

Techne biological stirrers provide a controlled stirring for delicate mammalian and plant cells. The gentle movement causes a spiralling mixing which ordinary spinner flasks find hard to achieve. Growing conditions have therefore proven to be ideal for cells grown in suspension or on microcarrier beads and for production of monoclonal antibodies. Important features include.

- Unique SOFTSTART stirring action to prevent cell damage.
- Calibrated speed control and interval stirring.
- Virtually heatless operation for incubator use.
- Special patented vessel and stirrer rod ensures good Thompson flow with vertical and horizontal circulation
- Vessels contain no bearings or mechanical parts and the borisolicate siliconised glassware is easily autoclavable.
- Six culture vessel sizes from 125ml to 5000ml.
- Maximum size unit now takes four 5 litre vessels.

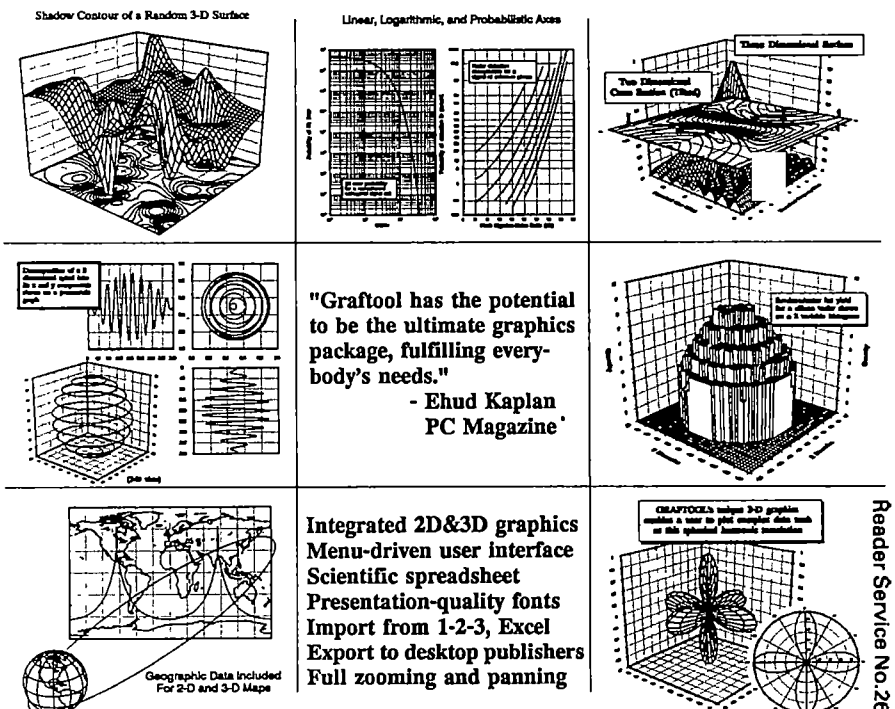
Genetics of Neuropsychiatric Diseases

Edited by ***Lennart Wetterberg***
Department of Psychiatry,
St Goran's Hospital, Stockholm, Sweden

In the search for genetic links to schizophrenia and other etiologically unclear neuropsychiatric diseases, it is useful to learn how genes have already been mapped and genetic defects discovered in some related diseases. **Genetics of Neuropsychiatric Diseases** includes examples of both.



Also included are a gene map of neuropsychiatric disorders and diseases, enzymes and proteins of neuropsychiatric interest, as well as reports on DNA techniques and DNA linkage, and chromosomal aberrations as tools for gene mapping.

The book also discusses the research findings and clinical practice of several diseases. New techniques and the recent finding of a gene segment linked to schizophrenia are reviewed.

Biotechnology Serving Medicine

Medica Dusseldorf, the unique combination of international trade fair and scientific congress will provide an opportunity to examine latest developments in biotechnology and gene technology. For medical diagnosis and therapy. In addition, innovations in medical technology, pharmacy and information technology in medicine. More than 1,000 exhibitors from 24 countries, more than 800 delegates representing all specialisations and almost 100,000 qualified visitors from all over the world

Exhibitor seminars offering practical advice.

New this year: Medica Juristica offering information about current legal issues affecting medical practitioners. Medica Doctors' Club, a centre for professional communication.

Mikhail Gorbachev is back

The pre-winter equinox is a time for getting back to serious business. Mr Gorbachev and his counterparts in the West have a great deal to do before they let the northern winter take over.

MR Mikhail Gorbachev's return from his annual summer vacation is fast becoming an annual global catharsis. When he is away, Moscow is filled with dark rumours and the mutterings now allowed by *glasnost*, while the rest of the world acts as if it has been unsettled. Then he comes back. Sometimes (as two years ago), he announces that he has written a book. On other occasions, as last week, he contrives confidently to sound as if insoluble problems are also the only problems with which it is worth bothering. Russia would not be the driving force in the Soviet Union if there were not an infinity of insoluble problems, but some, even so, are conspicuous.

There is, for example, what is called the ethnic problem, about which Gorbachev would appear to his predecessors (and does to his contemporary conservative opponents) to be curiously indifferent. Hungary plans to follow Poland, in the autumn, with a kind of free election, the three Baltic states behave as if they wish they could be up in arms, there is discontent throughout the southern republics and Moldavia would reunite with Romania if only that were congenial, but meanwhile demands the right to speak Romanian. The difficulty, for the Soviet republics, is that there are too many of them to cut much ice. Their friends elsewhere are mostly remittance men. In due course, it may be different, but many other things will by then have changed the world.

Second, there is the problem of the Soviet economy, which is bankrupt. The Soviet people cannot feed, or clothe or adequately house themselves. Gorbachev has railed against Stalin as energetically as anybody in his position could, but he has not yet spelled out what needs most simply to be said: that Stalin's exercise of his unchallenged right to squander half a century's investment of the Soviet people's enthusiasm on misguided enterprises is a more serious offence than his better-documented misdemeanours. Yet that is where the truth lies. Nobody asks that the Soviet people should repudiate the past half century, or even pretend that it never happened, but merely that Gorbachev, back from his vacation, should refer to the difficulty from time to time, by way of explanation of why that old enthusiasm has mostly been nugatory.

Third, there is the ideological problem. Gorbachev's licence as president of the Soviet Union is that of a leninist — the right to run a government on marxist lines. If the rules were different, he might have to apply for another licence; nobody can be sure what the outcome of that would be. The unspoken question at Gorbachev's return from his summer vacation is that the unspoken disloyal ideological question may now be unavoidable. If that were indeed the case, of course, everything would change. Gorbachev would probably retire, or take a post as president of a prosperous university in the West. It would be convenient for us all if that issue could be postponed for another year.

So what happens, or should happen, as the long winter closes in on the Soviet Union? First, there needs to be a recognition in the West that, of all the crises in the world, that in the Soviet Union should command the most attention. It is, after all, the most important potential crisis. If, this winter, there should be famine in the Ural district or somewhere else, there will be another Western-looking Dostoevsky, or perhaps several, on the West's back for the rest of time. Second, the outside world (not necessarily coextensive with the West) needs some kind of emergency plan. Third, quite soon, the US administration needs to settle on a plan for arms-control; Washington professes to be preoccupied with schemes for winning advantages from the present hiatus: why does it not offer a test-ban treaty (virtually completed nine years ago) as a gambit, knowing that there can hardly be a more secure agreement? □

No news is bad news

Impatience and intemperance may have persuaded the British government to cancel a timely project.

SQUEAMISHNESS is not one of the qualities on which the British government of the past decade prides itself. On the contrary, the government boasts (and even boasts about) qualities at the other end of the spectrum, toughmindedness for example. Yet Mrs Margaret Thatcher, the prime minister, has now used her considerable influence to stifle at birth a research programme meant to help understand the mechanism of the spread of AIDS in Britain. The objective is a social survey of contemporary adult behaviour, sexual behaviour included. The prime minister's office says that she considers that the study would have been "too intrusive" to be supported with public funds. Thatcher may be embarrassed to think of

20,000 of her electors answering questions she might prefer not to be asked herself, or she may fear for the consequences on the same respondents' voting behaviour. Either way, it is squeamish.

And worse. The survey now stopped in its tracks has been in gestation for the past two years. A large group of British AIDS researchers has devised not merely a list of questions to be asked, but methods by which they could be asked unobtrusively. A random sample of people (chosen from the Post Office Small Users' List) would have been invited to participate, but would have been free to refuse. The questionnaire would have been 'self-completed' in the argot of the social science trade: respondents would have completed the questionnaire themselves, sealing it into an envelope provided, referring to the survey official delivering the questionnaire only in case of ambiguity. Two pilot surveys, with 2,000 and 5,000 people respectively, have shown that the response is good and complaints a mere trickle. Arbitrarily calling a halt to such a careful project is a slap in the face for the whole of British science.

But it is worse than that. The titularly autonomous Economic and Social Research Council (ESRC), the most obvious British backer, approved the final version of the proposal as long ago as February, promising a contractual commitment within the week. Because its own budget is only meagre, ESRC had by then recruited the Health Education Authority and the Department of Health as co-subscribers to the estimated cost of £510,000; plainly the council had an obligation to consult the bigger money-bags, but equally plainly it had cause to believe that agreement would be a formality, both partners having been fully consulted along the way. But that week and about 30 more came and went with nothing happening — except that the Health Education Authority at one stage decided not to continue paying for the cost of the second pilot study it had agreed to share. Letters to ministers (one from a House of Commons select committee) went unacknowledged. Even a parliamentary question was somehow overlooked. Maladministration is the polite name for muddle of that kind, but there is squeamishness as well. Even if the prime minister's colleagues had weakly passed the buck to her, it was squeamish of them to let last week's decision be so long delayed.

Worse still, this arbitrary decision will damage the chances that AIDS will be rationally managed in Britain. First recognized eight years ago, AIDS is still an emerging scourge. That so much has been learned so quickly about the mechanism of infection by the human immunodeficiency virus (HIV) and its palliation may be remarkable, but it remains an open question whether AIDS will be contained within the groups it now predominantly afflicts (homosexual and bisexual men, intravenous drug users and the recipients of blood transfusions) or will spread more widely, especially among heterosexuals. In the widely accepted terminology of Anderson and May (*Nature* **333**, 514; 1988), the crucial parameters are the likelihood that an infected person will infect a sexual partner and the rate at which people acquire new sexual partners. As drugs such as AZT are more widely used as palliatives of overt and (now) cryptic AIDS, the infectivity of people carrying HIV at different stages will also become important. Social surveys of the kind now planned are the only routes to understanding. By intemperately saying "No", Thatcher has denied her fellow-citizens both a basis for telling how widely AIDS will spread and — ironically — an incentive to mend their behaviour in prudent ways. □

A new beginning?

The British Association's stirring manifesto from Sheffield would be more compelling if it were more immediate.

THE British Association for the Advancement of Science, widely regarded as moribund, has managed to organize a second successful annual meeting in a row. This year, at Sheffield, the association has even issued a "Charter for Science", pleading for a more deliberate approach to the revivification of British science. The association and the distinguished signatories of its charter are of course right to say that the new effort should begin in the schools: where else? They are neglectful in not asking why it should be necessary to begin again, when only a few years ago it seemed as if other beginnings had matured into success. Good manners notwithstanding, it now makes very little sense that the distinguished survivors from a distinguished tradition should urge their fellow-taxpayers that if only more attention were paid to the quality and character of secondary education, Britain might yet recreate a Newton or a Darwin (neither of whom won a Nobel prize — they were injudiciously precocious). A little anger would have been more appropriate.

The truth about British science is that it has been made to serve as the living proof that it takes only a few minutes to get rid of something whose survival depends on the quality of people's spirits: the mechanism is simply to make them depressed. In Britain, the process has been sustained for the best part of a quarter of a century, but the demands of the past decade have been unnaturally cruel. University departments have been robbed of staff, research councils (while their budgets have been protected against inflation) have been told how to spend their money on wealth-creating projects and often, in their anxiety to please, have tried unsuccessfully to second-guess their sponsors (witness present official discontent with the practice, as distinct from the principle, of interdisciplinary research centres). The charter for science would have been more compelling if fewer of its signatories had been (or were still) party to the calamitous decisions of the past few years.

What is to be done? The British Association is right to say that it would be best to begin again in the schools, but even if that were feasible, could Britain (or any other

second-rank power) afford to wait that long? Another couple of decades, perhaps? Of course not. The effort in the schools to which the British Association would dedicate itself is essential, but is a long-term project. The immediate need is to find a way of helping researchers now in post to believe cheerfully in their work, even when the prospect that they will earn substantial royalty fees from industry is small. Maybe, the British prime minister's decision on the AIDS survey notwithstanding, the British Association will find an answer by next year. □

More funny money

The only solution of Europe's money problem is to require European states to accept ECUs as legal tender.

Mr Nigel Lawson, the British chancellor of the exchequer, is in a curious dilemma. Last week, which he spent at Antibes in the company of other finance ministers of the 12 members of the European Community, he argued vigorously (as is his wont) against the notion that there should be a common European currency and a central bank to go wth it. But next weekend he will be in the United States, arguing that Britain should remain the second largest subscriber to the International Monetary Fund, which is a perfectly respectable international central bank. Why the contradiction?

The puzzle is most easily explained by supposing that what Lawson said last weekend at Antibes was a kind of joke. Faced with the job (for which he volunteered at Madrid in June) of devising alternatives to Europe's plan for a common currency, he appears to have offered the notion that all European currencies should be considered equal, coupled with the hope that some in due course would come to seem more equal than others. Lawson appears not to have committed his plan to paper, so that it is not certain what he meant. That may not matter much, given that critics of the plan (among whom Lawson may be included) are unlikely to give it an easy passage.

But there is a need for a European currency. Otherwise the banks will be the only winners from the single market. But at this late stage in history, it can make no sense to devise some non-monetary substitute for a currency — germanium, or even palladium, would not suit. Notions that the commodity called energy would make the basis for the ideal unit of currency are of course mistaken; if currencies must be linked with commodities, the commodities must be otherwise useless, as gold used to be.

Nor can it make sense that there should be a kind of competition between national currencies, as Lawson proposes. the optimists may believe that good currencies will take precedence, but will it not still be advantageous to pay for good and services in the cheapest, not the most expensive currency, thus verifying Gresham's Law .... The obvious solution is to have two legal currencies everywhere — the national currency and the European Currency Unit. Then you feel your way. □

End of *apartheid*?

The South African election last week must be demonstrated to have been a hopeful sign or it will be the last.

White South Africa, which re-elected its Nationalist government last week with a reduced majority, has a nasty job to tackle next: it has to persuade its new government, elected on the basis of "moderate reform", that there is no such thing. Reform is either radical — of or pertaining to the root — or it is not reform. South Africa's immediate problem is that its new government, having survived an election marked by brutality against non-whites, unjustifiable even by the calculation that its performance would otherwise have been even worse, and the opposition more wedded to *apartheid*, may still be preoccupied with electoral arithmetic. The government must be made to understand that it is unique among elected governments in being the one whose success will hang on whether it can create the conditions in which there will be another election of any kind by which its successor can be legitimized

The article on page 96 by Dr Stuart John Saunders, the vice-chancellor of the University of Cape Town, and his colleagues typifies the process of persuasion that must be begun. Neither readers of this journal nor the government of South Africa should be lulled into complacency by the simplicity of what they have to say. It will be noted, for example, that Saunders *et al.* use the word "post-apartheid" often, especially towards the end of their article What does that mean? Simply, it means that they believe there will be a time when *apartheid* has disappeared, and when the need to provide secondary schooling for those whom white South Africans now constitutionally set apart will be so great that even traditionally proud universities may have to reset their sights at more practical goals than those of excellence. The comfort, for Saunders and his colleagues and the rest of us, is that they are by no means alone.

Mr F.W de Klerk, this week's new state president of South Africa, is strangely more isolated. His difficulty may no longer be electoral, but he has assiduously sought (and won) the sufferance of people outside South Africa (in Zambia as well as Western Europe) by his assurances that reform means the root-and-branch stuff. If his election last week had passed off peacefully, he might have had some time in which to demonstrate that he meant what he said. As things are, there is less time — indeed, there is very little. The release of Nelson Mandela is at the top of every reformer's list, but should be a formality Abolishing the Group Areas Act, or something like it, by the end of the month would be more to the point. But the enduring need is to find the funds with which to educate all South Africans. If de Klerk does not hurry in that direction, others elsewhere should take on the burden. Whatever happens, people will be keeping a close eye on South Africa. □

New York State leads on genetic fingerprinting

■First attempt at regulation
■New labs and databank proposed

Albany, New York

The first attempt in the United States to regulate the forensic use of 'genetic fingerprinting' was announced last week by the director of justice for New York state, John Poklemba. According to a plan likely to be approved and implemented next year, the state would establish a committee to set and monitor standards, and a scientific board to examine the accuracy of test results before they could be presented in court.

There is at present no federal or state legislation regulating DNA testing in private or public laboratories. Although the need for some kind of monitoring is widely acknowledged, there is much dispute over who should do it. And the dispute will grow hotter as more state forensic laboratories carry out DNA testing.

Only one of the nearly 300 forensic laboratories in the United States now does DNA testing, according to a survey carried out by the Congressional Office of Technology Assessment (OTA), but a draft OTA report on the forensic use of DNA tests says that interest has "skyrocketed" in the past two years, and that most laboratories have plans to start testing in the next two years.

The report also warns that if no national regulatory action is taken, "continued case-by-case examination of proper technical and operational standards could slow full implementation of forensic analysis using DNA typing".

The Federal Bureau of Investigation (FBI), a leader in forensic DNA analysis, is holding a series of meetings with researchers and laboratory representatives aimed at reaching a consensus on technical standards. The group is said to be close to agreement on the main issues, and next month's meeting may be the last.

But there are objections to the leading role of the FBI, an investigative and law enforcement body, in setting standards.

Next month, the National Academy of Sciences will begin a comprehensive study of the technical, legal and ethical issues involved in the forensic use of DNA analysis, having obtained promises of funds from a variety of sources including the FBI, the National Institute of Justice and the National Institutes of Health. A report is expected in late 1990

The regulations proposed for New York have been warmly welcomed by researchers and lawyers grappling with the problems created by the transfer of the techniques of DNA analysis to the courtroom. Peter Neufeld, a lawyer on the panel that produced the plan, said they would have prevented some of the problems that surfaced in the recent New York double-murder trial (see *Nature* **340**, 582; 24 August 1989). And Eric Lander, of the Whitehead Institute for Biomedical Research, who was an expert witness at the trial, called the plan "fabulous".

Among its recommendations is a proposal for at least three new state-run laboratories. According to the New York panel, "questions about the quality of the work being done by the private laboratories have not been satisfactorily answered, and the laboratories' adherence to accepted scientific procedures has not been demonstrated". It says that "sweeping claims of accuracy, stating that the probability of error is one in a million, or in some cases one in a billion" are "suspect". And it criticizes the laboratories for being "reluctant" to share information about their procedures If DNA testing results are to be accepted as evidence in courts, the techniques must be generally accepted as reliable in the scientific community. But the panel says that "it is difficult to reconcile the practice of cloaking a methodology in secrecy with the claim that the methodology is widely accepted".

The DNA analyses carried out by the state laboratories, expected to cost about $500,000 to set up, would be equally available to defence and prosecution and the costs would be apportioned by some mechanism other than on a per-case basis. "Decisions on whether DNA analysis will be applied in a given case should be made on the merits of the case, not on whether there is sufficient money in the budget to pay for the analysis", says the panel. And in order to generate population statistics, all data generated should be kept but should not contain information traceable to an individual

According to OTA, resources for training forensic laboratory staff are "woefully inadequate". At a meeting of the OTA advisory panel last week, chairman Thomas Caskey of Baylor College of Medicine said that the United States is lagging behind the United Kingdom in the forensic application of DNA analyses and more funds for training are needed. He also said a committee should be formed to set national guidelines on quality assurance.

Under the New York plan, private laboratories could still perform DNA testing, but would have to be accredited by the state; this would require independent validation of the methods used and participation in state proficiency testing programmes. Approval by a scientific review board, which would set minimum scientific controls and examine the tests used, would be necessary before the results could be presented in court. The panel says that the usual method of determining whether a technique is generally accepted in the scientific community, by publication in peer-reviewed journals, is "inappropriate and unrealistic" in the case of DNA analyses in forensic work.

The panel also recommends the creation of a DNA databank, provided there are regulations to prevent use of the databank for any purpose other than identification of suspected criminals.

Only a computerized code allowing identification would be stored, and a match should not be the sole basis for making an arrest.

This strikes "an appropriate balance between competing privacy and legitimate law enforcement interests", says the panel. It also strongly urges the establishment of national standards for all testing procedures, analysis, interpretation and coding of data so that databases can be shared as well as quality controls to be carried out nationally. The FBI is due later this year to release a report on the establishment of a national database.

Several states have already enacted legislation that requires DNA testing of convicted sex offenders, and legislation is under consideration in others. But no state has yet established a databank.

Christine McGourty

SPACE

Japanese success

Tokyo

OFFICIALS of Japan's National Space Development Agency (NASDA) last week breathed a sigh of relief as an H-1 rocket successfully carried a meteorological satellite (GMS-4) into orbit. An attempt to launch the satellite a month ago failed because the first stage of the H-1 rocket did not fully ignite (*Nature* 340, 493; 17 August 1989).

There were fears that NASDA might have to postpone the launch until next year because launches from NASDA's space centre on Tanegashima island base are limited to particular periods by an agreement with local fishermen. A large sea area close to the base has to be cleared before each launch. The satellite, named Himawari (Sunflower) No. 4 will be moved to a geostationary orbit in about a month and is expected to provide meteorological data for the western Pacific region for five years starting in mid-December.

David Swinbanks

JAPANESE BUDGET

Space science is a winner

Tokyo

JAPAN's space scientists and astronomers find favour in the 1990 budget request just submitted by the Ministry of Education, Science and Culture (MESC) to the Ministry of Finance. Although total funds for space science are reduced, the budget is full of small but significant requests for 'seed money' to begin major new projects in space science and astronomy. Global environment research also gets a boost.

The ministry's budget will not be finalized until the end of the year but is likely to pass the Ministry of Finance without major amendments.

One of the most significant items in the budget is a tiny request of ¥14 million ($100,000) in preparatory funds for a 7.5-metre infrared telescope to be built at Mauna Kea in Hawaii by the National Astronomical Observatory. The observatory, which until recently was part of Tokyo University, has been trying to win support for the telescope for years (see *Nature*, **311**, 5; 1984).

1980 Science budget request for Ministry of Education, Science and Culture

	thousand million yen	(% change from 1989)
Grants-in-aid of research	56.0	(+ 6 4)
Government/Industry research	11 4	(+10 7)
Donations from Industry	39.2	(+18 0)
Research fellowships	2.2	(+14 1)
Nuclear fusion	9.0	(+ 4 8)
Accelerator physics (TRISTAN)	16 4	(+ 3 2)
Space science	18 3	(−12 3)
Astronomy	0 9	—
Environment	4 0	(+32 2)
Earth Science	2.3	(+ 8 8)
Antarctic research	5 1	(+73.1)
International exchange	6.6	(+12 4)

The telescope will have a very high resolving power (about 0.1 arc seconds) and wide field of view, making it ideal for the study of the processes of formation of stars, planets and galaxies. The total cost of the telescope and related facilities is expected to be about ¥45,000 million ($312 million), more than twice the amount estimated in 1984 when plans for the telescope were first made public.

Also hidden away in the budget request is a small allocation for the development of a new solid fuel rocket for the Institute of Space and Astronautical Science (ISAS) The rocket will have about three times the power of the institute's present biggest rocket the MU-3SII and will cost about $150 million to develop. One of its first missions will be to launch a radio-telescope satellite (see page 92). And the budget for space science will rise after 1990 as development costs of the rocket and satellite increase.

Radioastronomy gets another big boost with a request for ¥845 million ($6 million) to build a heliograph at the Nobeyama Radio Observatory of the National Astronomical Observatory The heliograph will consist of a T-shaped array of 76 80-cm parabolic antennas. It will be completed in two years at a total cost of about ¥1,900 million ($13 million) and will observe solar flares during the next solar maximum in conjunction with the solar observation satellite Solar-A, which is scheduled to be launched by ISAS in 1991.

The global environment features prominently in MESC's budget request as it did in the already-released budget requests of other government ministries and agencies (see *Nature* **341**, 4; 1989). And, similarly, some of the money is to be used to establish new research centres.

The Research Institute of Atmospherics at Nagoya University will be reorganized into an institute provisionally named the Solar Earth Environment Research Institute at a cost of $1 million (¥136 million). The institute will study the inflow and outflow of energy and materials from the Earth and Sun and the effect of these fluxes on the global environment

A similar amount (¥224 million) is requested to reorganize and rename the Sand Dune Research Institute of the University of Tottori. The revamped institute will broaden its horizons from the study of local sand dunes to research on the deserts of the world. And ¥26 million is requested to establish an Arctic research centre at the National Institute of Polar Research.

Funds for joint international research on the global environment rise 10 per cent above this year's level to ¥3,239 million ($22.5 million). Extra backing goes to joint research on the Arctic environment in collaboration with the United States, Norway and other countries Antarctic research also receives a huge increase (73 per cent) to ¥5,069 million ($35 million) but much of the extra money is a one-time allocation for the purchase of a ship-borne helicopter. **David Swinbanks**

■ "DONATIONS from industry", one of the biggest items in the budget request, are funds donated under a scheme established by MESC in 1983 Such donations are the fastest growing source of support for university researchers and are expected to reach nearly ¥40,000 million ($280 million) in fiscal 1990. The government's contribution — ¥11,400 million ($80 million) in fiscal 1990 ("government/industry research" in table) — has also grown rapidly, and the total budget for the scheme now almost matches MESC's budget for research grants. □

GENETIC SCREENING

UK physicians demand action

London

ADVANCES in methods for genetic screening and prenatal diagnosis should be available to all couples wishing to have children, the British Royal College of Physicians (RCP) has recommended. Education about genetics should begin at school, should be a part of the medical school curriculum and should also become a part of clinical practice.

In a report published on 7 September, the RCP claims that many British couples are denied access to up-to-date screening techniques and prenatal diagnosis and that the availability of these tests varies four-fold between different health authorities, the administrative organs of the National Health Service. The report says that the test for spina bifida, available since the 1970s, is offered to only 70 per cent of women at risk, while amniocentesis for Down's syndrome is available at only 12 hospitals in Britain.

The report recommends that a nationwide screening and prenatal diagnosis scheme should be established, which would become an intrinsic part of maternal health care. Professor Martin Bobrow, a clinical geneticist at Guy's Hospital Medical School who helped to write the report, said a comprehensive screening and back-up system of diagnosis could prevent the birth of 2,000 severely handicapped babies a year. The RCP concludes, after a cost-benefit analysis of the scheme, that "if the costs of the whole programme were aggregated, it is cheaper to screen and counsel the whole population than it is to treat affected childen who would otherwise be born to unprepared couples". The cost of a test is a few pounds, the cost of caring for a severely handicapped child is about £10,000 a year. Dr Margaret Turner-Warwick, RCP president, said short-term budgetary considerations meant that health authorities did not think in terms of long-term saving.

Sir Raymond Hoffenberg, a past RCP president and a member of the working party, said an integral part of the plan was to improve education. Many women were not offered tests simply because general practitioners and hospital consultants were unaware of what was available. The report says a designated co-ordinator should be responsible for organizing delivery of both specialist and community genetic services in each region.

A code of practice should be drawn up to tackle the inevitable ethical problems involved. Bobrow said prenatal diagnosis would not be used for positive eugenic policy, but to enable individuals to make informed decisions about their lives based on the fullest possible knowledge.

BIOTECHNOLOGY LICENSING

Greens oppose EPO plant

Munich

OPPONENTS of genetic engineering from all over West Germany descended on the sleepy university town of Marburg last week to present a wide assortment of objections to a biotechnology plant for the production of the drug erythropoietin (EPO), which stimulates the creation of red blood cells in patients with kidney failure. In protesting against the plant, the opponents, led by the Green party, took advantage of a long-awaited opportunity: the first public licensing hearing in West German history for a gene-technology facility.

The licensing battle is an important test case for the future of industrial genetic engineering in West Germany. It could affect the 'framework law' for genetic engineering scheduled to be debated in parliament this fall. Other companies, including BASF AG, are facing similar hearings in the next few months.

Both Behringwerke AG, which owns the plant, and the Greens expect the plant to be licensed despite the protest, and both expect a legal battle to follow Behringwerke had applied to produce EPO in 1988 but submitted its application again after the law was changed to require a public hearing (see *Nature* **335**, 199; 1988).

The licensing authority, which in this case is the regional government in Giessen, announced that it would rule on the application by the end of the year.

The Greens made an impressive showing at the hearing both in the volume and the content of their objections. There were nearly 2,000 written objections to the plant, many of which concerned the moral and ethical aspects of genetic engineering. But the Greens also raised technical objections that they claim Behringwerke had not been expecting.

For example, Regine Kollek of the Greens objected to the genetic vector used to transform mouse cells in culture and induce them to produce EPO Kollek claimed that bovine papilloma virus 1 (BPV 1) is present in the cells in its entirety and that a single virus particle might cause harm to humans.

The Greens called for data on the genetic lineage of the mouse whose cells will be used for the cultures, in order to determine if the mouse carries viruses such as mouse mammary tumour virus (MMTV) that might increase the chances of recombination, with unforeseen genetic consequences.

Behringwerke responded that these charges are "scientifically irrelevant." For instance, Behringwerke denied that BPV 1 might appear in either the cells or the EPO itself. The company reported that the cell line in question has been used for 15 years without any evidence that endogenous retroviruses might be activated. But Behringwerke spokesman Wolfgang Faust said that the company expects to be asked for further documentation before a license is granted.

Marina Steindor, spokeswoman for the national Green party working group on gene technology, said the Greens made "great progress" at the hearing. Steindor said that public hearings should be a part of the licensing procedure for all biotechnology products.

In the proposed genetic engineering law, hearings would not be required for some production processes involving "harmless" strains.

The issues raised at the licensing hearing would sound familiar to those United States companies that first won permission a decade ago or more to use genetic engineering for the production of drugs. But whereas the US debate came to be dominated by pragmatism, the German debate is marked by the opposition's almost religious adherence to the belief that all genetic engineering is hazardous and should not be allowed anywhere. Those concerned seem prepared to resort to any legal means to prevent companies from using this technology.

Behringwerke must leap more hurdles, for instance in obtaining a licence to sell EPO, even if the production licence is granted.

But despite all the difficulties, Behringwerke is not considering pulling out of West Germany. "We're a Marburg company," said Faust. "We've invested DM10 million [$6 million] in the plant already. It would be senseless if we could not use it."

Steven Dickman

RADIOASTRONOMY

Japan plans a space VLBI

Tokyo

JAPANESE scientists hope to be the first to launch into orbit a satellite that can be linked to radiotelescopes on Earth to form a huge VLBI (very-long-baseline interferometry) network.

The VLBI Space Observatory Programme (VSOP) is being promoted by the Institute of Space and Astronautical Science (ISAS) in collaboration with researchers at the Nobeyama Radio Observatory of the National Astronomical Observatory and the Communication Research Laboratory, and was described at an international symposium in Tokyo at the end of last month. A recent decision by the Space Activities Commission to allow ISAS to build a larger solid fuel rocket (*Nature* **340**, 8; 6 June 1989) has given a boost to VSOP, and preliminary funds for the project are included in the budget request for fiscal year 1990 just submitted by the Ministry of Education, Science and Culture (see page 92).

ISAS hopes to launch the VLBI satellite in early 1995. Its closest competitor was the European Space Agency (ESA)'s VLBI- satellite QUASAT But ESA cancelled the project last year, leaving only Japan and the Soviet Union in the field, given that the United States has no plans for a VLBI satellite The Soviet Union hopes to launch the Radioastron satellite in 1993 but Japanese scientists involved in VSOP think it is likely to be delayed.

The orbit of the VSOP satellite will have an apogee of 20,000 km and, when linked to radiotelescopes on Earth, will create a VLBI radiotelescope network with an effective diameter of 30,000 km — about three times the size and resolution of the biggest networks on Earth.

Radiotelescopes in the United States, Europe, Australia and Japan will participate in the programme. Discussions are under way with the Soviet Union according to Haruto Hirosawa, professor of remote-sensing engineering at ISAS. The structure of the central cores of quasars, active galactic nuclei and other compact radio sources will be studied and their relative positions and motions obtained with "unsurpassed accuracy" ISAS scientists say.

Under an earlier plan, the antenna of the satellite would have been limited to a diameter of 5 metres because of the small lift capacity of ISAS's biggest rocket, the MU-3SII. But the Space Activities Commission in June approved a proposal by ISAS to develop a solid-fuel rocket with three times the power of the MU-3SII which has allowed ISAS scientists to double the planned size of the antenna to 10 metres, says Hirosawa.

Various ingenious designs for the antenna were presented by companies at the symposium last month, including an inflatable antenna design put forward by Kawasaki Heavy Industries and a mesh antenna design by Toshiba. But ISAS has decided to give the contract to Mitsubishi Electric Corporation for a tension truss design. NEC will handle the rest of the satellite and communications.

The total cost of the satellite is not yet certain but, according to Jun Nishimura, director general of ISAS, it will not be much more than that of previous ISAS satellites. They typically cost a few tens of millions of dollars, while the larger rocket for the launch will cost about ¥5,000 million ($35 million).

ANTARCTIC ENVIRONMENT

Keeping the South Pole clean

Washington

A SERIES of accidents in the Antarctic this year, coming on top of accusations that US research bases are polluting the Antarctic environment, is causing increasing concern over US Antarctic policy. At a Senate hearing last week to assess the progress of the National Science Foundation's (NSF) clean-up operation, the debate widened into general discussion of how to protect the Antarctic environment. Next month, the Senate must decide whether to ratify the Convention on the Regulation of Antarctic Mineral Resource Activities (CRAMRA), which would in principle allow commercial mineral exploration and extraction to begin.

Even with less than a thousand researchers and a few thousand tourists in the area, damaging accidents have occurred. Peter E. Wilkniss, director of Polar Programs at NSF, told the Senate Committee on Commerce, Science and Transportation that the Argentinian vessel wrecked in January off Palmer station (*Nature* **337**, 495; 1989) still contains 60,000 of diesel oil, which is slowly leaking into the ocean. James N. Barnes of the Antarctica Project said that two other accidents took place in February, involving the Peruvian ship *BIC Humboldt* and the British resupply vessel HMS *Endurance*. Although both accidents went largely unreported, either could have caused serious marine pollution.

The diesel spill occurred in a dangerous offshore channel near Palmer station despite warnings from US personnel. According to Barnes, Antarctic navigation is made more difficult by the lack of a single set of accepted charts.

The frequency of accidents and lack of international cooperation increases concern over what might happen if Antarctica is opened up to commercial mineral exploration. At present even prospecting is banned, although seismic surveys have been conducted for 'research' purposes. The ban was agreed as a temporary measure while CRAMRA was being negotiated If ratified by 16 of the 22 member states, CRAMRA would allow mineral exploration and development, although each project would have to be approved by all members and strict environmental standards would be imposed.

Both Australia and France have expressed opposition to the convention, and a number of other Antarctic Treaty member nations are thought to be ambivalent. Australia favours a permanent ban on mineral development, but R. Tucker Scully, director of Marine Science and Polar Affairs at the State Department, said this would be not only undesirable but also politically impossible, because a consensus of nations would be required.

Most independent environmental organizations oppose CRAMRA; Barnes argued that CRAMRA's mere existence would spur commercial competition and accelerate development. But the Ocean Resources Institute takes a different view. Its director, Lee Kimball, feels that "international laws are more durable than political bans" and sees the regulations of the convention as necessary protection in the unwelcome but not unlikely event that mineral prospecting will take place.

Of more immediate concern to both environmental groups and the US government is the mess created by 30 years of research activities. Reports produced last summer by environmental groups (*Nature* **334**, 643; 1988 and **337**, 399; 1989) have accused NSF of polluting the unspoilt polar environment, and NSF has admitted that corrective action is needed. One problem is not knowing what has been dumped or released into the environment in the past: Wilkniss says that divers have stumbled upon bulldozers of which there is no record. Some progress has been made in cleaning up old buildings, outdoor storage areas and re-landscaping landfill dumps, but open burning of rubbish continues in contravention of applicable international law and raw sewage is still discharged into the sea. The NSF is requesting $10 million in 1990 as the first increment in a $180-million, five-year environmental health and safety initiative for it's Antarctic Program.

Environmental issues will be high on the agenda when Antarctic Treaty states meet in Paris next month. Australia has proposed a "comprehensive environmental protection" convention, and the United States has suggested a more permanent infra-structure, in the form of a secretariat that could take responsibility for ensuring compliance with the regulations that exist.

Penelope Austin

CERN

Finland to join

London

FINLAND **is to start negotiations with the European Laboratory for High-Energy Physics (CERN) with the aim of becoming the fifteenth member of the organization by 1991, it was announced in Helsinki on 29 August. Finland expects there to be a transition period after full membership during which its membership fee will gradually increase to its full contribution, calculated at almost 2 per cent of the CERN budget on the basis of spending figures for 1989. CERN welcomes the development, saying that it completes the geographical participation of Western European countries.**

Ben Webb

SPACE STATION

ESA tries to change NASA's mind

Paris

SENIOR **representatives of the European Space Agency (ESA) are this week returning to Washington in a further effort to persuade the US National Aeronautics and Space Administration (NASA) to abandon proposals to cut back on its Freedom space station (see *Nature* 341, 3; 7 September 1989). The plans, which could involve both an extension of the construction timetable and reductions in engineering specifications for Freedom, are unacceptable to both Japan and ESA and discussions in Washington last week failed to produce a solution.**

Dr Frederick Engström, ESA's director of space station and platforms, does not rule out the possibility of changing construction schedules and is optimistic that an "equitable" agreement can be reached "if everybody is willing". But, he says, "the situation is much deeper than this".

The current proposals, which include a halving of available power, would, he says, mean that "there are really no resources available to operate anything but a US lab" and fears that there would be "no technical way to get these resources back within an acceptable time". Rescheduling, he says, would make the Columbus attached laboratory and free flying laboratory "like an appendix" to the main schedule and, from an engineering point of view, "unwelcome".

Among alternative cost-cutting proposals being tabled by ESA are the possibility that, if only one attached laboratory is feasible, this should be built by the partners (ESA and Japan) and not NASA. Also, the US flight tele-robotic servicer could be deferred and its functions performed by the Canadian-built robotic arm until the space station reaches its original specification.

Common mechanisms for decision-making exist between ESA and NASA and, says Engström, decisions should be based on consensus. But NASA does have the ability to make decisions unilaterally if no consensus is reached. Memoranda of understanding (MOU) signed between ESA and NASA should have ruled out the possibility of the proposed change in schedule and specifications. "We will have to look at these MOUs", says Engström, "but above all, we have an international governmental agreement which has been signed and ratified. We will have to see whether these agreements have to be adjusted or not."

NASA is expected to reach a decision by the end of this month. Meanwhile, ESA legal experts are looking at the implications of changes in the agreements. The new proposals will be high on the agenda at ESA's science programme committee meeting on 20 September.

Peter Coles

GLASNOST IN PUBLICATIONS

Who's hiding primary data?

Washington

THE International Union of Crystallography (IUC) this month published a policy statement urging scientific journals to ensure that when researchers publish analyses of proteins, nucleic-acid and virus structures, they simultaneously make the primary data available, to allow independent verification of the results.

Increasing delays in the disclosure of primary data are causing heated debate in the crystallographic community and giving rise to accusations ranging from sheer sloth to unjustified suppression of data obtained through publicly funded research.

The standard way to provide the primary data is through the deposition of the structure's atomic coordinates in the protein databank at Brookhaven National Laboratory. Many researchers believe that journals have a role to play in encouraging faster deposition of coordinates

Last year, Frank Richards of Yale University wrote to several journals on behalf of almost 200 crystallographers urging them to "adopt and enforce" rules to make data more easily available. This would "ensure the preservation of important and expensively determined data which otherwise are likely to be lost". To satisfy researchers reluctant to release the data immediately, the databank could be instructed not to release the information until a specified date.

But the issue divides journals. The editor of *Science*, Daniel E. Koshland, Jr, is willing to agree to these guidelines, but advocates a coordinated effort by all the relevant journals. The *Journal of Biological Chemistry* has strengthened its guide to authors to encourage deposition strongly Others believe journals cannot act as 'watchdogs'. *Nature*'s line is that there should be as few obstacles as possible between an author and publication. Some journals argue that granting agencies, for example, could require appropriate disclosure of data.

Even if journals agreed to require deposition of data in databanks, whether this should be done at the same time as publication of a paper is controversial. Some researchers argue that it takes several years of refinement before a structure is ready to be entered into a databank: Ken Holmes, of the Max-Planck Institute for Medicine, says it is "general practice to withhold coordinates . . and up to a point this is legitimate".

But Tom Steitz, of Yale University, sides with those who believe that if a structure is ready for publication, there must be data which can be released.

Steitz says the difficulty will be in finding some middle ground between those who call for immediate deposition of all data, even those not included in publications, and those who advocate a five- to ten-year time lapse while the structure is defined.

Rumours are now circulating in the crystallography community that researchers are selling coordinates to private companies instead of making them publicly available. Graham Derby of Wellcome says the debate is fuelled by a changing atmosphere in research, in which academics "are being encouraged to profit from anything that is potentially valuable".

Christine McGourty

GERMAN UNIVERSITIES

Green light for plan for young researchers

Munich

A PLAN to keep talented young researchers at universities received preliminary approval in West Germany last week.

Representatives of federal and *Länder* governments gave tentative approval to the plan, which would require an investment of DM6,000 million (about $3,060 million) over ten years.

The plan, announced by Education Minister Jürgen Möllemann in May, is meant to prepare for an expected wave of retirements of university professors in the years 1995 to 2005 (see *Nature* 340, 252; 1989). Möllemann also plans to make funds specifically available to women in universities, where they have traditionally been under-represented.

As many as 5,000 young people would be supported in the programme's first year, and up to 50,000 would be supported at the end of the plan, said an Education Ministry spokesman.

Final approval will have to wait. A meeting originally scheduled for 21 September between Chancellor Kohl and the heads of the *Länder* at which the plan was to be discussed has been postponed because of Kohl's poor health. Steven Dickman

BRITISH COUNTRYSIDE

Row ahead on conservation

London

A ROW is brewing between the British government and conservation organizations over plans to split the the Nature Conservancy Council (NCC) across the national boundaries of England, Scotland and Wales. The proposals first surfaced in the summer, when Nicholas Ridley, then Secretary of State for the Environment, said the proposals were designed to "improve the way we handle conservation of wild fauna and flora and the countryside".

Ridley said that the "circumstances and needs" of England, Scotland and Wales are very different and that the present system of nature conservation are inadequate. The responsibilities of the NCC, which looks after nature conservation throughout Great Britain, and the two Countryside Commissions (CC), one covering England and Wales, the other Scotland, would be altered The CCs are responsible for enhancing the natural beauty of the countryside.

The functions of the three bodies will be "exercised in future by separate bodies for England, Scotland and Wales", Ridley said "The conservation and countryside functions should be the responsibility of a single body in each country." But the government intends that because of the density of population and the greater pressure on land in England, the NCC and CC there will be retained as separate bodies The changes "require legislation which we shall bring forward at the earliest opportunity", Ridley added.

One of the more contentious issues will be the future of the scheme for designating and conserving "sites of special scientific interest", at present the responsibility of NCC; these range from habitats for valued animal and plants species to sites of geological or archaeological interest. Among other means of conservation, NCC administers a scheme for paying compensation to landowners for restraint in land exploitation, but more often the scheme has been resented (and even resisted) by those seeking to develop land.

The forthcoming debate will be an occasion when the British government will have further to define its plans for encouraging farmers to pay more attention to environmental considerations. But it is unlikely, at this late stage, that even those opposing the government's proposed reorganization will seek to put back the clock to when NCC had a research capability of its own, long since transferred to the Natural Environment Research Council.

But Sir William Wilkinson, chairman of NCC, says that the plans could "damage" the cause of conservation. He said conservation in Britain faces "complex challenges" and "mounting financial restraints" and that the proposals do nothing to help. "Wildlife issues are no respector of geographical or political boundaries", he said, while the separation would "undermine" the scientific capability of the NCC and "prevent effective policy advice being provided to government". In their present form the proposals would "weaken" the NCC's capacity to play a "co-ordinated and positive role" **Ben Webb**

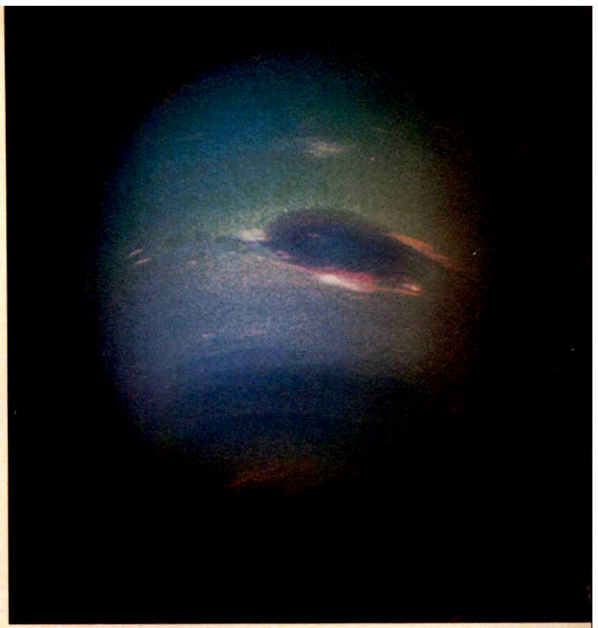
Considered view of Neptune

Washington

THE spectacular shot, shown below, of Neptune's ring system was taken by Voyager 2 as it looked back towards the planet. In sunlight reflected at a glancing angle, the fainter rings and dust bands are clearly visible, but a comparison with pictures of the rings taken as Voyager approached Neptune (see *Nature* of 31 August) shows an intriguing difference: the outermost ring, significantly brighter on the approach shots, shows up here a little fainter than the prominent inner ring.

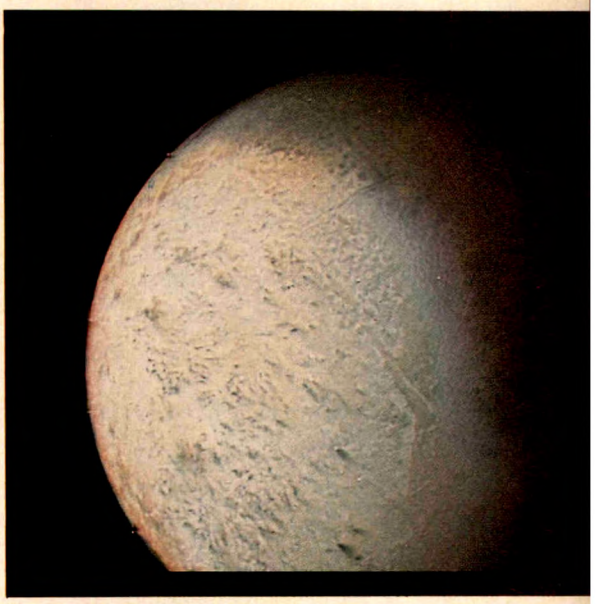
The difference is a clue to the composition of the rings. Particles bigger than the wavelength of light, about half a micrometre, scatter most of the radiation incident upon them directly backwards, towards the light source; smaller particles scatter more light forwards than backwards. Thus most of the ring and disk material around Neptune, except for the outer ring, is 'dust' — although a more apt comparison for the size of the particles would be 'smoke'.

An extended disk of fine material was presaged by another Voyager experiment. The plasma-wave detector, two long antennas arranged in a V, also acts as a dust detector. As Voyager 2 speeds on at several miles a second, any dust particles it encounters vaporize on impact: the ionized shock front from this tiny explosion carries a characteristic burst of radio noise, which the plasma antenna picks up.

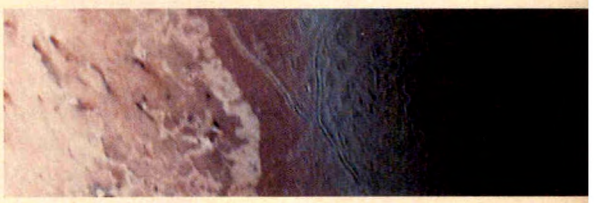


Because the frequency of the radio noise from the dust impacts is in the kilohertz range, it can be replayed directly as an audio signal: this led to a moment of drama in the Neptune encounter. As Voyager 2 passed through the equatorial plane on its way to closest approach, at about twice the radial distance of the outer ring, the hissing and crashing of the dust was played live through loudspeakers at the Jet Propulsion Laboratory. As the noise reached a maximum, it abruptly ceased; Voyager's radio signal was lost behind Neptune, to be recovered 45 minutes later.

Calculations of the encounter rate with dust around Neptune's equator suggested a maximum density of 0.003 particles per cubic metre. This is more dust than found around Uranus, and its presence, along with the 'clumpy' outer ring, reinforces the idea that Neptune has had a more interesting recent history than its sister planet. Explaining the denser segments in the outer ring will be the hardest task: two theories already on the books both seem to be misses. In the first, two guiding satellites, one at the same orbital radius as the ring and one just inside, create perturbations to the gravitational field that allow material to reside stably in restricted arcs; at Neptune, none of the four new satellites near the ring is in the right place. In the second theory, a satellite with an orbit inclined to the ring plane creates similar perturbations, and 1989N6 is indeed in a circular orbit tilted at 5 degrees. But it seems too small for its gravitational influence to be able to stabilize the dense ring segments.



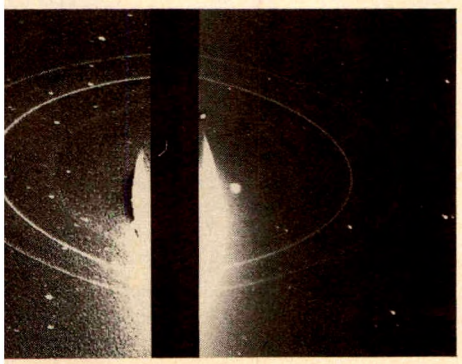
In another respect, Neptune and Uranus are twins: both have magnetic fields whose axis is tilted, at about 50 and 60 degrees respectively, markedly from the rotation axis. This presumably has something to do with the internal structure of the planet. Unlike Earth, which has a hot, semiliquid core whose internal motions generate the terrestrial magnetic field, the rocky cores of the giant planets are small, cold and inert. Outside this core there is probably a thick layer of liquid water existing, because of the huge pressure, in an ionized phase. The dynamo for these planets may reside in this turgid but mobile region.



The tilted magnetic field complicates Neptune's magnetosphere, and its interaction with the solar wind. Detectors on Voyager found evidence for charged particles trapped by the magnetic field, but the density was unexpectedly low. The magnetosphere, whose geometry is controlled by a tilted magnetic pole rotating about a planetary axis itself tilted with respect to the plane of the Solar System, may not be permanently isolated from the solar wind: from time to time, particles trapped within it can be swept out into interplanetary space.

David Lindley

A false-colour composite of UV, violet and green reveals the altitude of Neptune's clouds. The bright pink cirrus clouds are above most of the atmosphere, which absorbs UV radiation and darkens the deeper clouds. The Great Dark Spot appears blue; it lies at an intermediate height from which blue light, but not UV, can escape.



A false-colour view of Triton, taken on Voyager's approach. The pink hue approximates to the real colour of methane ice, but the blue represents UV light: sadly, Triton is not a blue moon. The strip below, a composite of several shots, shows the variation in terrain. The feeble heat of Triton's summer is thought to sublimate surface ices, breaking up the smooth surface into the blotchy covering at left.

The largest of Neptune's 'new' moons, 1989N1, turned out to be oddly shaped. At about 250 km in radius, and thought to be made of deep-frozen water ice, it could not be any bigger without its own gravity forcing it into a spherical shape. Below, the rings in their full splendour, seen as Voyager looked backwards after passing by Neptune.

Towards the day of hard choices

Jon File, Annamia van den Heever and Stuart John Saunders

When apartheid breaks down (as it must), South Africa will need a new, non-racial educational system. Moves to that end are already afoot.

LAST week the National Party was returned to power in South Africa. Although the party has promised reform, most South Africans expect that the essentials of the system of apartheid that divides South Africa from the rest of the world, and its people from one another, will not be fundamentally changed.

Since 1953, when Hendrik Verwoerd first enshrined racially divided education in the Bantu Education Act, education policy has been the cornerstone of 'separate development'. Rejection of apartheid education sparked the Soweto student uprising of 1976 and the ensuing 13-year-old crisis that shows no signs of ending. For several months now many schools have been closed. Police are regularly in school playgrounds and some university campuses have at times been occupied by security forces. F. W. de Klerk (himself until this month Minister of National Education) and his incoming adminstration have inherited this legacy — for them, as for their predecessors, educational issues will continue to be central as apartheid continues to disintegrate in the face of internal and external pressure.

Background

The National Party's policy makers, who codified the principles of apartheid into legislation from 1948 onwards, were quite clear about their intentions. White, coloured, Indian and African* were to live apart, and whites were to retain political and economic dominance. In consequence, education should be to the appropriate level. Verwoerd was explicit that, for Africans, this meant no more than the minimum training required for manual labour. Whites, on the other hand, had to be educated to lead and, in the case of Afrikaners, to preserve the Afrikaner heritage. 'Christian National Education' was based on the view that Afrikaners were a distinct Christian nation, with a language, history and culture of their own. The language of apartheid may be more sophisticated now than it was 40 years ago, and some changes have occurred, but racially segregated education remains the foundation of South Africa's education structure.

* In this article we use the term 'black' to refer collectively to all those denied full political rights by the system of apartheid. The racial designations 'white', 'coloured', 'Indian' and 'African' are those used by the state in administering apartheid.

Under the philosophy of Christian National Education, the school system is governed by a multiplicity of education departments, each with its own examination system, syllabuses and standards. A common feature is authoritarian control. The same philosophy has also divided the universities. Although some tertiary institutions were founded specifically to service apartheid, the four English-speaking open universities (Cape Town, Natal, Rhodes and Witwatersrand), as well as the University of the Western Cape, have vigorously opposed the imposition of apartheid framework. The Extension of University Education Act (1959), which introduced a 'permit system' for black students wishing to study at universities designated 'white' by the government, was vigorously fought. Legislation in 1983, which replaced the notorious permit with a ministerially determined 'racial quota', was also resisted, with the result that although the provision is on the Statute Book no quota has ever been enforced.

Table 1 Comparative statistics for South African schools, 1987

	White education	African education
Pupil:teacher ratio	16:1	41:1
Underqualified teachers (less than standard 10 plus a 3-year teacher's certificate)	2%	87%
Per capita expenditure	R 2,508	R 477
Standard 10 pass rate	94%	56%

R, South African Rand
Source: J Hofmeyr & R. Spence *Bridges to the Future* in *Optima* Vol. 37, No. 1 (1987).

These five universities have consistently opposed the encroachment on academic freedom and freedom in general: from the imposition of successive states of emergency, banning and detention without trial, censorship and restrictions of the press, to restrictions and bannings of individuals and organizations. In 1987 the Universities of Cape Town, Western Cape and Natal successfully challenged, in the Supreme Court, a government attempt to link state subsidy to the control of political activities on university campuses. The five universities have usually stood alone, although staff and students at other universities, particularly the predominantly black universities, have not been silent.

Those tertiary institutions that have made a principled stand against apartheid remain inexorably bound to the wider crisis in education. Black students at the open universities are tremendously disadvantaged, and academic support programmes are essential. Black candidates for university admission often require full bursary support if they are not to be denied further education for purely economic reasons. Political conflicts often erupt in the pockets of relative freedom on the open campuses. For these and other reasons, educational issues in South Africa have to be seen on a broad canvas.

Schools

A recurrent feature of popular uprisings since 1976 has been school boycotts by black pupils protesting against the iniquities of apartheid, including the education they receive. Although the state response to such boycotts in 1976, 1981 and 1984–1985 was to increase further the already harsh restrictions, the government announced in 1986 its intention to achieve parity in education according to a Ten Year Plan. This would have increased expenditure on education by 4.1 per cent per annum in real terms. But this year the Minister of Education stated that this goal could not be achieved. "As far as education is concerned we are in a tight spot", he told parliament, citing the main reason as the low growth in the economy, due partly to sanctions and disinvestment (*Hansard*, No. 11, cols 5555–5559; 1989). Thus although there have been some improvements in recent years (particularly in the greatly increased financial provision for black education which has expressed itself in better qualifications and salaries of black teachers and facilities for black schools), huge disparities remain. Table 1 shows the stark differences between white and African schools in pupil:teacher ratios, teacher qualifications, per capita expenditure and pass rates. At the same time, the white school-going population will decline from 954,000 in 1987 to 899,000 in the year 2020, while projections for the African school-going population show that it could more than double from 6,645,000 in 1987 to 14,977,000 in 2020. (Figures from E. Dorstal's *Notebook on Educational Trends and Perspectives*, Institute of Futures Research, University of Stellenbosch; 1988.)

More than a decade of instability coupled with inadequate resources has led to a situation in urban black schools today in which very little education is taking place.

Drop-out rates are high. Teachers, caught between the administrators of apartheid and their own communities, are demoralized. Pupils lack the will to learn. Parents have little control and discipline has almost completely broken down. Illiteracy in South Africa is estimated to be as high as 50 per cent.

Universities

A sustained crisis in secondary education obviously has severe effects on tertiary education. These effects and the response to them vary, and are modulated by the place of individual institutions within the framework of apartheid education.

Some 420,000 students are currently enrolled at higher-education institutions: 300,000 at universities, 68,000 at technikons and 53,000 at teacher-training colleges. These figures are part of a trend of rapid increase: in 1966 70,000 students were registered in South Africa's universities, while over the past three years alone an additional 60,000 students have been awarded places. Over the next ten to fifteen years the expected three-fold increase in the number of matriculants, the great majority of whom will be African, will continue this exponential demand for university places. But rather than challenging the structure of separate education, the increases in enrolment are having little effect on the system of racial segregation and discrimination.

Despite the abolition three years ago of the permit system, which restricted access to universities on the basis of race, the effect of apartheid is still starkly evident (Table 2). Ninety-eight per cent of students at universities designated African in the original structure of apartheid education are African, and 96 per cent of students at Afrikaans or dual-medium universities, are white (the University of South Africa, or UNISA, is a non-residential, distance-learning university that has always been open). Looked at another way, although slightly more than a third of current university students are African, 51 per cent of them are at the eight African universities, 39 per cent of them are studying by correspondence through UNISA, 2 per cent of African students are at the University of Durban Westville (originally an 'Indian' university), a further 2 per cent are at the University of the Western Cape (intended as a 'coloured' university) and 5 per cent are at historically 'white' universities (almost all of them at the English-speaking universities). These figures must be set against South Africa's demographic structure: there are over 30 students per thousand of the white population and fewer than three students per thousand of the African population (see *Macroaspects of the University within the Context of Tertiary Education in the RSA*, Committee of University Principals; 1987). It is difficult to escape the conclusion that, despite changes in legislation, Verwoerd's vision of separate education has been successfully realized in the university system as well as in the schools.

Additional biases are less immediately evident, but are of crucial importance. With the exception of Medunsa (a medical university established for blacks), the natural sciences are best developed at the 'white' universities. Together with the low standards of mathematics and science education in African schools, this has meant that Africans have mostly studied the humanities, social sciences and education and, to a lesser extent, law and commerce. Similarly, postgraduate study is concentrated at the 'white' universities: only 5 per cent of South African masters and doctoral students are African. It is not surprising that 91 per cent of the permanently appointed academic staff in South Africa in 1986 (the most recent year for which comparative figures are available) were white and less than 5 per cent African.

As with the schools, the present basis of financing is not sufficient to allow universities to do much about these inequalities. While the South African government allocates a respectable 20 per cent of public expenditure to education, and universities receive a sizeable 15 per cent of this, the joint consequences of past neglect and future demand have created a financial crisis. Thus the government has cut back its intended support for universities by some 25 per cent. Per capita income to universities is increasing at about half the rate of inflation. Government budgetary planning is based, at most, on annual increases of 1–2 per cent in real terms. Government policy is to rationalize the university system and to limit growth through the exclusion of marginally qualified entrants.

Although these forces act in concert upon the university system their effects vary from institution to institution. The educational challenges arising from inadequate schooling are faced primarily by the black universities, and on a lesser but perhaps more complex scale by the four English-speaking open universities given the wide range of educational backgrounds of their first-year students. Acute demand for university places is faced only by those universities committed to improving access for African students. The financial situation is worsened for these same universities. South Africa has no national student financial aid programme. The costs of a year of study at a residential metropolitan university exceed even the minimum annual wage levels negotiated by strong Trade Unions with more enlightened employers. In this context, universities committed to increasing African access have had to invest heavily in financial aid programmes, and to give them precious fund-raising priority.

Current debates

The crisis in South African education has aptly been described by Hartshorne as an interregnum in which (following Gramsci) "the old authority is dying and the new cannot be born" and where, as a result, "a great variety of morbid symptoms appear" (*Post-Apartheid Education*, to be included in *Critical Choices for South African Society*, Oxford University Press; 1989). The South African government has consistently repressed organizations working towards a non-racial future. Hundreds of people involved in education have in recent years been detained without trial or have had severe restrictions imposed upon them. Nevertheless, there has been a great deal of debate about alternatives to apartheid education.

At school level the debate has centred on fundamental issues. Among them are the extent to which education should serve the individual, society and the state, the nature of a 'relevant' curriculum and who should determine relevance, and the question (given that South Africa is multilingual) of whether students should receive mother-tongue education and for how long. When in a school career should a common language (which one?) be used as the medium of instruction? Given the demographic realities of South Africa, is mass formal education possible? Who should pay for it — the state, private enterprise or both? Where does authority end and authoritarianism begin?

Both Christian National Education and Western-style liberal education are under scrutiny. Liberal education is viewed by some as fostering élitism and competitiveness, and entrenching capitalism, and as a vestige of colonialism. An emerging, alternative philosophy is 'People's Education', which can be regarded as a set of proposals which flesh out the educational principles contained in the Freedom Charter (a declaration of political aspirations and intent formulated during the Congress of the People, organized by the African National Congress at Kliptown in 1955). The structures envisaged in People's Education are unitary and non-racial, and organized so that all parties involved in education — students, parents, teachers, workers — have a part in its management.

These debates are echoed at the university level. Questions are being raised about how the curriculum and research priorities should reflect South Africa as a part of Africa; the role of the curriculum and the university in reproducing inequalities, not just by race, but also by gender and class; the balance between research generated by disciplinary interests and that initiated in response to national needs; the extent to which teaching and research should concentrate on the needs of government and big business at the expense of those of the broader community; links between universities and the

military and the armaments industry; and the democratization of university power structures and many other issues.

A wide range of educational programmes has developed in parallel with this broad debate. The English-speaking open universities and the University of the Western Cape are islands in a hostile environment, but it has still been possible to initiate imaginative projects in educational development, academic support for educationally disadvantaged students, and devising appropriate selection criteria. Large investments in personnel and in time have been made in order to build a non-racial ethos and appropriate industrial-relations practices. Financial-aid programmes have been introduced. Student residences were fully integrated in spite of the Group Areas Act.

There are also encouraging developments outside the universities. Within the state school system there have been calls for open schools from white-teacher organizations and white parents, and there are moves towards teacher unity on a non-racial basis. Some white-parent organizations, and business, have been questioning the relevance of the education white pupils are receiving. Innovative programmes are being negotiated and adopted elsewhere, in private non-racial schools, in organizations involved in informal, adult and worker education, in literacy programmes, in upgrading programmes for teachers, to name but a few. Attention is also being focused on the education departments in the non-independent 'homelands' and 'independent' states where 70 per cent of African pupils are at school. It is now recognized that the 'homelands' cannot be wished away and that their peripheral nature to the central system could offer opportunities.

Characteristic of the innovations taking place are painstaking attempts at community consultation in order to legitimize not only the programmes but the process used to derive them.

Underlying all of this activity is the explicit recognition that political transformation is a pre-condition for any real educational solution. The government's Ten Year Plan for education, its funding formula for universities and the noticeable lack of effect that changes in legislation have had on enrolment patterns across the university system all show that apartheid education cannot be reformed. Any real solution must be a post-apartheid solution.

Along with this political transformation will come hard policy choices. Should increased education expenditure take priority over programmes addressing health care, agricultural development, housing, water and sanitation, and energy and electrification? Post-apartheid South Africa, even with an improved economy and savings from reduced defence expenditure and the scrapping of separate systems of adminstration, is unlikely to be able to afford a university system that allows access at the rates currently enjoyed by white students, or a school system funded at the same level as white schools. What relative priority should literacy and numeracy programmes, pre-primary, primary and secondary education, adult and worker education, technikons and universities receive within the education budget? The issues are complex, the answers as yet unknown. What is clear, however, is that difficult choices are inevitable, and that the process by which such choices are made will need wide support and legitimacy if there is to be success.

Table 2 University enrolment in South Africa

Intended population group in terms of government policy	Number of universities	Total enrolment April 1989 (nearest 1,000)	Enrolment by population group (%)			
			White	Coloured	Indian	African
White						
(a) English medium	4*	47,000	74	5	9	11
(b) Afrikaans or dual medium	6†	67,000	96	2	<1	1
Coloured	1‡	12,000	2	77	4	18
Indian	1§	7,000	4	2	61	33
African	8‖	54,000	<1	<1	<1	98
UNISA	1¶	113,000	50	5	9	37
Total	21	300,000	52	6	6	35

* Cape Town, Natal, Witwaterstrand and Rhodes. † Orange Free State, Port Elizabeth, Potchefstroom, Pretoria, Rand Afrikaans and Stellenbosch. ‡ Western Cape (UWC). § Durban Westville (UDW). ‖ Medical University of South Africa (Medunsa), North, Zululand, Bophuthatswana**, Transkei**, Venda**, Fort Hare**, Vista. (** 1988 figures are used. These universities are situated in 'independent states'.) ¶ UNISA, although administered by the white education department, has traditionally been open to all. Source: Department of National Education.
In 1986 the South African Institute of Race Relations estimated the population of South Africa, based on the 1985 census but adjusted for undercount, to be: African 24,901,139 (74.1%); Indian 878,300 (2%); coloured 2,881,362 (8.6%); white 4,961,062 (14.7%).

Such support and legitimacy will be facilitated if those sectors of South African society that are currently excluded from policy debates and decision-making structures are drawn into them. Although the tempo of immediate political struggle often lowers the priority given to future-orientated projects, their importance needs to be emphasized. All concerned with education have to begin to address the questions of how the universities will deal with national personpower, with research and development needs, with ensuring an indigenous scientific technological and professional base, with contributing to the formation of a new South African nation, and with redressing the historical inequities of access across all universities and at all academic levels.

Competing social priorities in post-apartheid South Africa will probably mean that growth in university places is restricted, or even reduced. In higher education, preference may need to be given to the expansion of technikons, and to the natural sciences in both technikons and universities. Given that full-time student enrolment may be limited, increasing emphasis on distance education, part-time study, continuing and adult education, and increased access to universities through the wide dissemination of research results and a broader availability of university expertise through consultancy and community projects may all become priorities. These issues need careful research and discussion before the day of hard choices dawns.

Conclusion

Although the government received a white mandate for reform in last week's election, the struggle for a non-racial, democratic South Africa will be a long one. The "old authority is dying" and there are indeed many "morbid symptoms", but there are also the signs of new life, a common culture on which a strong education system can be built.

Those within the South African educational system who have grasped the opportunity to begin to anticipate the future need help. Among the institutions and sectors involved are emerging non-racial schools, future-directed literacy and education programmes, the English-speaking open universities (of Cape Town, Natal, Rhodes and Witwatersrand) and the University of the Western Cape, and staff groups at the black universities who take the brunt of the challenge and work with most of South Africa's African students. Financial aid for black students is a key priority if lack of money is not to become the main inhibitor of black access to university. Carefully selected support for these and other areas will hasten the day when a unitary non-racial education system, that serves the needs of the new South African nation, will be achieved. □

Jon File, Annamia van den Heever and Stuart John Saunders are at the University of Cape Town, Rondebosch 7700, South Africa.

ACKNOWLEDGEMENTS. We thank colleagues involved in South African education for helpful discussions, and particularly Martin Hall for his editorial advice.

Policing animal experiments

SIR—A letter from Mr Clive Hollands appeared in *Nature* (**339**, 248; 1989) stating that experiments published in this journal earlier in the year (**337**, 265; 1989) would have been illegal had they been carried out in the United Kingdom. It took two weeks for *Nature* to point out that this was an expression of opinion and not legal fact (**339**, 407; 1989). Your error in publishing the letter without proper consideration was compounded by the inappropriate and emotive heading for your leading article ("Beastly experiments") the following week. This headline puts *Nature* in the same category as *The Sun* and *Sunday Mirror*. The antivivisection campaign of the *Sunday Mirror* against Professor Colin Blakemore was recently investigated by the Press Council, which found that the basis of the campaign was false and required the publication of that adjudication.

Unfortunately, much of the subsequent correspondence (for example *Nature* **340**, 180; 1989) seems to have taken more notice of Hollands' incorrect assertion than of your belated article setting out the correct position. It is important that your readers, whatever their personal opinions about the use of animals for research, should know that in the United Kingdom there is a new Animals (Scientific Procedures) Act (1986) which controls the use of such animals. All scientists in the United Kingdom using animals for research must hold a personal licence and be covered by a separate project licence, both issued by the Home Secretary after appropriate application and consideration. Section 5(4) of the Animals (Scientific Procedures) Act (1986) states: "In determining whether and on what terms to grant a project licence the Secretary of State shall weigh the likely adverse effects on the animals concerned against the benefit likely to accrue as a result of the programme to be specified in the licence". The experiments Hollands complains of have not been put to the Home Secretary and therefore it is not known whether they would be allowed in the United Kingdom. Hollands is a member of the Animal Procedures Committee that advises the Home Secretary on matters relating to the licensing of scientists to carry out animal experiments. He therefore knows or should know what the law states. There is good reason to believe that Hollands was advised before sending his letter to *Nature* that it would be inappropriate for him to claim that these experiments would be illegal in the United Kingdom.

Nature has done a great disservice to biomedical research in this country. You should attempt to repair the damage by a proper apology to the French scientists whose work you have effectively repudiated and by a discussion of the likely adverse effects on both medical and fundamental research of your too ready acceptance of an antivivisectionist's minority viewpoint. Blakemore has been and still is the subject of an aggressive personal attack by antivivisectionists. This attack now appears to be spreading to his colleagues around the world. Their work on the development of the visual system is of the highest order and has led to important advances in the understanding of both basic mechanisms and clinical problems that may arise in the young. It is high time that Blakemore and those other scientists, who have been pilloried for their work by a tiny but aggressive minority, were properly and publicly supported by international organs of communication such as *Nature*, and by government and charitable organizations that provide much of the financial support for research involving animals.

Reprints' function

SIR—In spite of the plethora of letters to *Nature* regarding the pros and cons of honouring reprint requests, a major point seems to have been missed by those against. Gone are the days when a scientist could make a leisurely trip to the library, leaf through the three or four journals of interest to him/her, and photocopy the few articles of interest. There has been a tremendous 'information explosion' in both the number of journals in any particular field and the number of articles. To a scientist who wishes to maintain any breadth of knowledge, even within a highly restricted field, this is simply no longer possible. It would require two or three days each week of exclusive library work.

That increasing numbers of scientists are making use of commercial computer searches and associated reprint requests is a reflection of this change within the scientific community. It is neither a reflection of laziness nor of selfishness on the part of the reprint requesters, as suggested by Peter Johnson (*Nature* **339**, 170; 1989). Rather, it is a reflection of time economy, combined with a desire to keep up with the literature.

On the other hand, some scientists, according to Johnson, apparently resent the "throwing [of] the burden of time and cost onto the author". The time taken to mail reprints is considerably less than in searching out an article and mailing it, especially as most requests are accompanied by easily used return addresses. Thus the real problem appears to be the cost. This seems to me to be a predictable cost that granting agencies are willing to accept as an appropriate item on a budget. For those without grants, it could be an item for negotiation with their departments as an administrative cost as essential to any science department as writing paper or secretarial support.

Scientific endeavours are meaningless if not communicated to others in the appropriate scientific community. Given the nature of contemporary science, the problem of this communication (of which the honouring of reprint requests is an important element) is not a trivial issue. Perhaps it is time for the recognition of the necessity of the dissemination of scientific information, and a general agreement as to whose shoulders the responsibility for this dissemination should fall upon.

No to South Africa

SIR—I am one of those who have stuck their necks out and said "No" to science from South Africa. I have done it because I believe that the inviolateness of the practice of science is not absolute; its precedence is relative and must be judged against the enormity of the racial injustice in that country. Racial injustice is being practised in many countries, but it is the scale of it in South Africa that stands out. One of the arguments against boycotting South African science is that it harms innocent scientists. I would weigh this against the harm being suffered by millions of innocent blacks at the hands of a much smaller number of whites. If the black leaders believe that sanctions and boycotts will help to change their situation for the better, then I will support them in this way. Who else should we listen to but the victims?

JOHN ORMEROD

Does the Earth really move?

SIR—John Durant (Britain's first Professor of the Public Understanding of Science) *et al.* (*Nature* **340,** 11–14; 1989) complain that "only 34 per cent of Britons and 45 per cent of Americans ... were able to state correctly both that the Earth goes round the Sun and that it takes a year to do so". They clearly implied that the 30 per cent of Britons who responded that the Sun goes round the Earth are mistaken, and they actually stated that "most of the public appear not to have caught up with Nicholas Copernicus and Galileo Galilei". But look what Albert Einstein and Leopold Infeld wrote in their book *The Evolution of Physics* (Cambridge University Press, 1938, p. 224):

> Can we formulate physical laws so that they are valid for all coordinate systems (cs), not only those moving uniformly, but also those moving quite arbitrarily, relative to each other? If this can be done, our difficulties will be over. We shall then be able to apply the laws of nature to any cs. The struggle, so violent in the early days of science, between the views of Ptolemy and Copernicus would then be quite meaningless. Either cs could be used with equal justification. The two sentences, "the sun is at rest and the earth moves", or "the sun moves and the earth is at rest", would simply mean two different conventions concerning two different cs. Could we build a real relativistic physics valid in all cs; a physics in which there would be no place for absolute, but only for relative motion? This is indeed possible!

This important lengthy passage is quoted in full lest the incredulous reader might not trust this writer's word. Most of the public may not have caught up with Copernicus and Galilei, but it appears that most of the professors have not caught up with Einstein. Should not the public expect professors of the public understanding of science to be acquainted with the most basic facts of science before they complain that most of the public are ignorant of scientific matters?

Reasonable doubt

SIR—Eric S. Lander's Commentary and your accompanying leading article (*Nature* **339,** 491 and 501; 1989) raise the question of reconciling scientific and legal thinking. However, while the mere fact of the appearance of these publications demonstrates that science is pursuing its usual practice of self-criticism, I have seen no evidence that the law is doing anything to modify its practices in the light of scientific advance.

I wish to raise here two issues involving probability, which figures in both the contributions referred to. While most would agree that someone cannot be "60 per cent guilty", it is quite possible that there may be an x per cent probability of guilt. In some cases the probability can be quantified with some exactness, and the question then arises — what probability represents the 'reasonable doubt' beloved of the legal profession?

In my experience, lawyers do not want to address this question, perhaps because it takes the matter out of their hands and puts it in the hands of scientists. But surely a legal consensus should exist, and be known to all members of the profession.

A second issue (which crops up quite frequently in the courts) is where death rates due to a given illness in a particular cohort are raised above the normal level by local external circumstances. When the arguments are purely statistical, we may know that $n+m$ individuals have died instead of the expected n, but it is impossible to determine whether any particular individual is one of the m or one of the n. In other words, it is impossible to say in any individual case whether the external circumstances were or were not the cause of death. I have never heard of this argument being raised in any of the large number of cases involving this type of circumstances that have been or are being tried.

It will be interesting to see whether lawyers are prepared to exercise the same sort of self-criticism as do scientists, and review their attitudes to circumstances such as those described above (there are many others) where science is at present either ignored or distorted.

Complications

SIR—In a News and Views article (*Nature* **338,** 457; 1989), John Maddox uses the word "complicated", but I think "complex" is the right word. The word 'complex' is now a technical term used by physicists and computer scientists. A non-living static structure can be very complicated, but it need not be complex. Complexity results from dynamics. If a structure can, in principle, be described completely, it is not complex. Complicated non-living static structures are not complex because they can be described with sufficient accuracy in a finite time.

Complexity of dynamic systems is connected with unpredictability. In classical mechanics, it is assumed that the entire future is predictable in a deterministic system. But this is true only for linear deterministic systems.

Linear systems are those that can be divided into parts, and each part can be studied in isolation. Not much information is lost when the system is divided. The Solar System can be linearized in the sense that Earth–Sun, Earth–Moon, Sun–Jupiter subsystems of the Solar System can be studied in isolation without significant loss in the accuracy of the results. That the eclipses can be predicted so accurately exemplifies that linear systems are not complex.

Nonlinear deterministic systems, on the other hand, are complex. "Deterministic chaos" (Gleick, J. *Chaos*, Heinemann, London, 1988) is an example of a complex system. A chaotic system can be modelled with simplistic deterministic equations, yet the model cannot be used to predict the long-term time evolution of the system. It can be proved rigorously that the equations of the model can predict the entire future of the system exactly and uniquely *if we can specify the initial conditions exactly*. In practice, however, we can never determine the initial conditions exactly in real systems.

The crucial difference between chaotic and ordinary dynamic evolution is the effect initial error has on predictability. In ordinary evolution, errors grow linearly and they can be corrected by subsequent observation. In chaotic evolution, errors grow exponentially rapidly and cannot be corrected. Chaotic systems are thus complex. This is so in spite of the fact that they can be specified by simple equations.

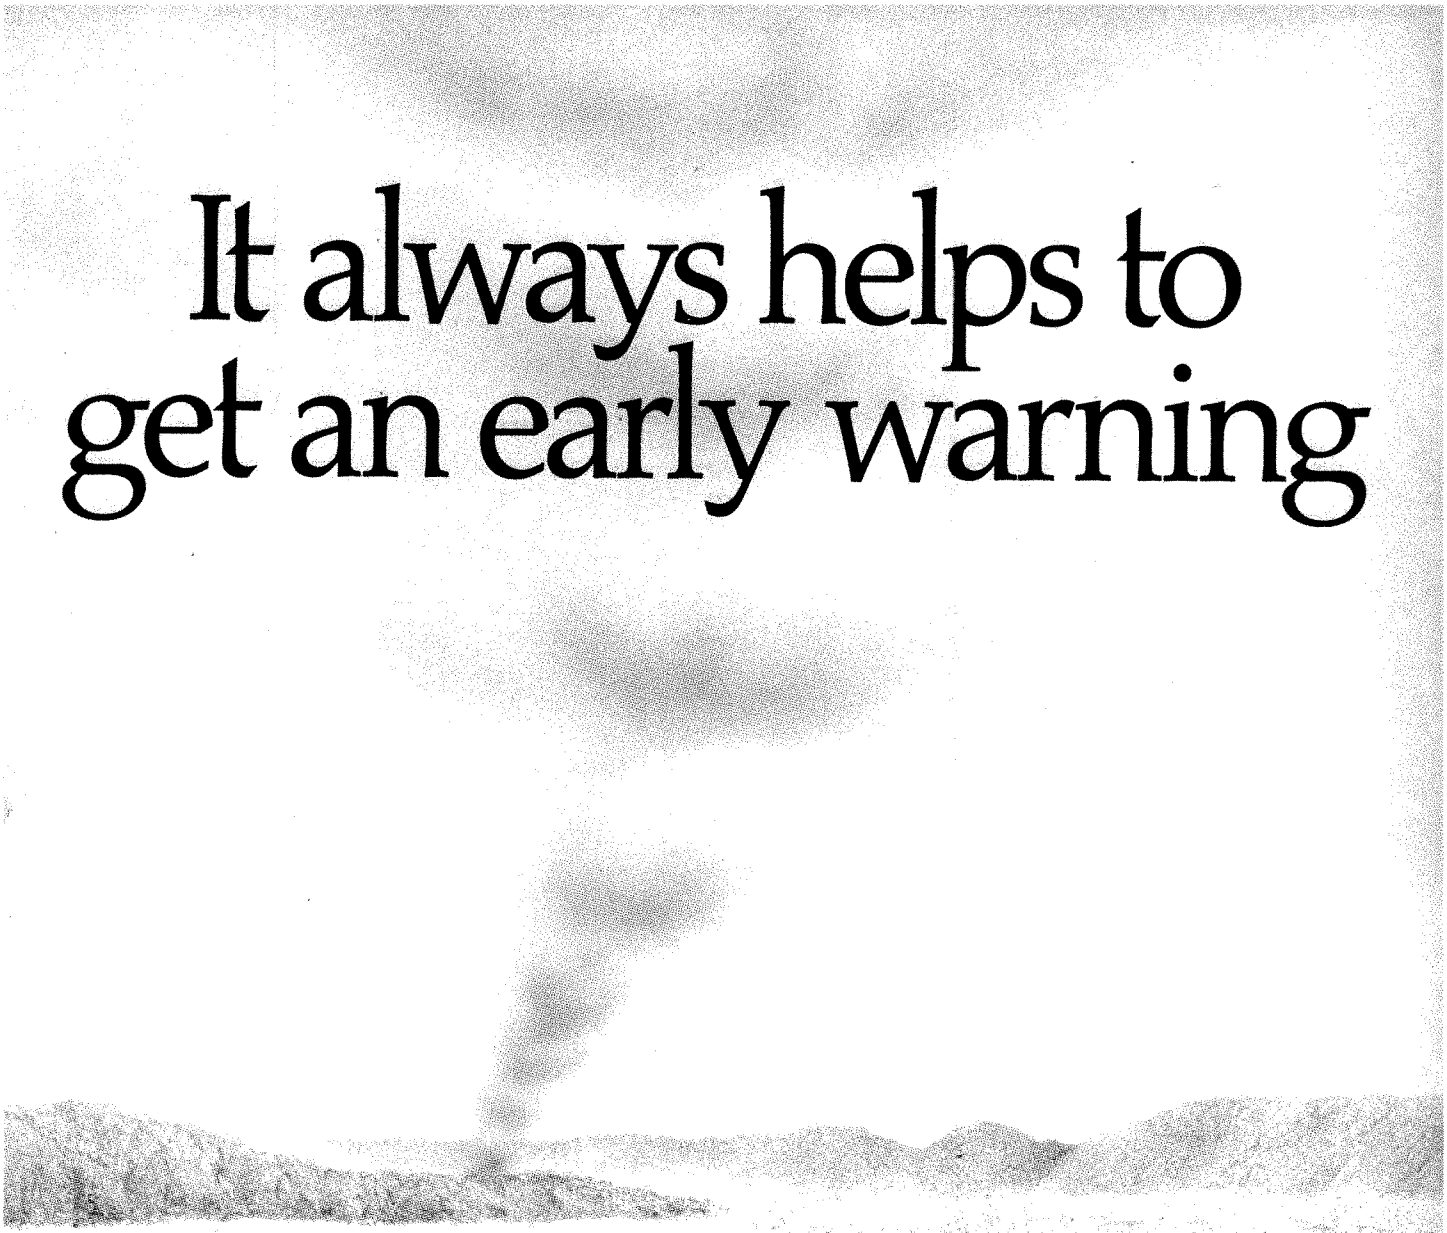
Before the event



SIR—It seems that you are caught on the horns of a philosophical dilemma ("Down with the Big Bang", *Nature* **340,** 425; 1989). You reject an oscillatory view of the Universe at least partly on the grounds that "the ultimate origin of our world cannot be discussed". You therefore reject as unsatisfactory an endless sequence of causes in a time which has no beginning. In the preceding paragraph, you object to the Big Bang because it implies the existence of an instant before which there was no time, and which is not susceptible to discussion of causes preceding the event. Surely this objection applies to any discussion that presumes to account for the "ultimate origin of our world"?

I have always thought it unlikely that a defence of the First Cause would ever appear in your columns. Now, however, I am not so sure.

IT IS NOT WORTH TAKING THE SHOT IF YOU ARE UNCERTAIN ABOUT THE QUALITY OF YOUR PEPTIDES.

You can waste a lot of time, effort and money on your research if you are not sure about the quality of your peptides. At NEOSYSTEM we feel you should not have to make the choice between price and quality. Thanks to our multi-peptide synthesiser developed in house, we are able to produce many different peptides simultaneously. This means we can offer high quality peptides at low costs with short delays. Contact us now to discuss your custom peptide requirements.

3 levels you can choose from :

GOLD	minimum 98 % pure 900 * FF/residue	HPLC profile, amino acid analysis sold by net peptide weight 15-20 mg
SILVER	minimum 85 % pure 650 * FF/residue	HPLC profile, amino acid analysis sold by net peptide weight 25-50 mg
BRONZE	minimum 60 % pure 400 * FF/residue	1 step purification , 200-300 mg

* all prices +/- 20% depending on sequence and amount required.

HIV RESEARCHERS: ALL THE TOOLS YOU NEED

TO FIND OUT WHAT MAKES IT TICK

British Bio-technology announces a wide range of research tools to help you defuse the AIDS time bomb.

Designer Genes for HIV-1

Transactivator protein	(TAT)
Virion Infectivity Factor	(VIF)
Negative Factor	(NEF)
Regulator of Expression of Virion proteins	(REV)
Protease	

All Designer Genes can be used to express proteins for function studies and for the production of antibodies, whilst VIF, NEF and REV can be used to produce DNA probes.

Amplification Primers

Three pairs of primers to different regions of the HIV-1 virus are now available.

Gene	Primer	Fragment b.p.
POL	T/S →	604
POL	B/S ←	
p24	T/S →	620
p24	B/S ←	
p17	T/S →	396
p17	B/S ←	

T/S → Top strand sequence priming in rightward direction (forward primer)
B/S ← Bottom strand sequence priming in leftward direction (reverse primer)

Amplification primers are designed for use with most common strains of HIV-1 but please enquire for strain specific primers.

TAQ Polymerase

A thermostable enzyme, free of contaminating nuclease activities.

TAQ can be used with amplification primers and for DNA sequencing, and is supplied with full data outlining quality control and optimum conditions for use.

For further information on Designer Genes, Amplification primers or TAQ polymerase write or phone today.

British Bio-technology the arms dealers in the battle against HIV.

British Bio-technology Limited

British Bio-technology Ltd., Watlington Road, Cowley, Oxford. OX4 5LY. Tel: (0865) 781045. Fax: (0865) 717598. Telex: 838083 BIOTEC G.

Reader Service No.201

Racemization rationalized

Do chiral partner molecules crystallize together as racemic crystals or as separate enantiomers? There is no general rule, but now at last there are the beginnings of a working model.

ONE of the heroic true legends of our time is that Pasteur demonstrated that asymmetrical carbon-based molecules are optically active by sifting through the small crystals obtained from a solution of a racemic mixture, putting those with gross left-handed symmetry to one side and those with right-handed symmetry to the other. That was the first proof that molecules that are chiral (mirror images of each other at a centre of asymmetry) are physically distinct, but it also shows that in Pasteur's case, the enantiomers crystallize separately. That is not a general rule. Just as often, the enantiomers crystallize into a racemic crystal with equal numbers of asymmetrical molecules.

All that is, of course, the familiar stuff of the elementary textbooks, providing telling illustrations of the value of Gibbs' phase rule and of much else in physical chemistry; small proportions of one enantiomer will indeed depress the melting point of the other, for example But how to calculate the behaviour of particular pairs of enantiomers? Will enantiomers preferentially crystallize separately or together, for example? The phase diagram for the first case is the simpler; whichever enantiomer is in excess will be the first to crystallize from the melt, driving the remaining liquid towards 50:50 composition. If, on the other hand, a racemic crystal can exist, racemic crystals will appear directly from cooling melt with a composition centred on equality, and there will be two eutectic points on either side of 50:50 composition at which the solid that appears will be a mixture of racemic crystals and those of the enantiomer. Can the details of this behaviour be predicted?

Plainly that is not a simple question. Something needs to be known of the energy of interaction between enantiomorphic pairs in various conformations and then, usually still more difficult, of the way in which they will be ordered in a crystal. Now David Andelman, of Tel Aviv University and the Collège de France, has made a start on the problem by constructing a model of how enantiomeric pairs may behave in two dimensions (*J. Am. Chem. Soc.* **111**, 6536; 1989)

Andelman explains that the two-dimensional version of the problem is not without interest in its own right. Membranes in biological systems are, for example, loaded with chiral phospholipids, while the inter-molecular interactions controlling the properties of, say, a two-dimensional Langmuir–Blodgett film will at least be a sub-set of those effective in three dimensions. Indeed, two-dimensional studies should make it possible to define the interaction energy as a function of intermolecular distance. Andelman offers a model which is a neat way of ordering ideas likely also to stimulate further work

Andelman uses the simplest possible model of a chiral molecule, centred on a tetrahedral carbon atom linked to four distinct groups, of which three are supposed to be anchored by their chemical affinity to a two-dimensional layer (think of it as a membrane) while the third (visualized as, say, a long aliphatic tail) sticks out perpendicular to the surface. If the three groups bound to the layer are A, B and C, one enantiomer is represented by molecules in which A, B and C appear in alphabetical order reading, say, clockwise around the triangle; the other is the set of molecules in which the order appears as A, C and then B After suitable rotation of this 'tripod' molecule, the 'foot' of one molecule in the layer is a mirror image of the other.

It is not disparaging of Andelman's work to say that he has constructed what must be the simplest model there could be of an aggregation of such simple molecules: even that is difficult enough. The triangular feet of the molecules are supposed to interact only when two triangular faces are opposed to each other, which implies that only three orientations of the feet, differing by $2\pi/3$, are allowed. This has the consequence that the symmetry of any two-dimensional crystal that may be formed is hexagonal. The next step in the simplification process is to allow only for the interaction between groups in the triangular feet which are directly opposed to each other; interactions between next-nearest and more distant pairs of neighbours are neglected. Then the trick is to construct a partition function and derive the thermodynamic properties of the system from that.

Remarkably, some provoking generalizations (for the two-dimensional case) nevertheless appear to be possible. The parameters of the problem are the energies of interaction between the nine possible pairs of closely opposed groups, of which only six are independent (BC equals CB, for example) Andelman finds that, if all these interactions are due to Van der Waals forces, chiral segregation is energetically less favoured than the formation of the two-dimensional versions of racemic crystals. Or, at least, that is how it seems. In this case, the six independent parameters are reducible to three because the pairwise interactions may be expressed in terms of the polarizability of the three distinct groups, although Andelman has not been able to prove the result for all cases. If one of the three groups is electrically charged, the same result is likely, but strong interactions between oppositely charged groups bias the energetics towards chiral segregation in the crystal form.

The calculation of the phase diagrams is necessarily more difficult. To make the model correspond with some degree of realism to the case of molecules pinned to a two-dimensional layer but occupying what may be only a small part of it, while keeping the simplifying assumption that only three orientations of the tripod are allowed, Andelman is driven to a kind of lattice-gas model in which the vertices in a two-dimensional lattice are occupied by one of the enantiomers or by a vacancy.

Formally, this treatment is exactly like that of the simplest models of the adsorption of gases on the surfaces of solids. Despite continuing argument about the degree to which a two-dimensional structure, however well-ordered, can accurately represent a three-dimensional solid, two-dimensional lattice-gas models have at least the virtue of being exactly soluble.

The result is that Andelman is able to construct two generic phase diagrams, one each for the cases in which chiral segregation is preferred or not The general shape of the diagrams resembles that of those for the sublimation of enantiomeric solids, whether racemic crystals or not, but there is a tendency for racemic crystals not to appear, but to be replaced by pure enantiomer, when the composition is too far from equality. Differences between this behaviour and that of real solids are not too disconcerting: two-dimensional structures are not solids, after all

Part of Andelman's interest is to argue for the design of tripod molecules that could be studied in Langmuir–Blodgett films; it would certainly be interesting to know more about the structure of domains of chiral order. But there is probably still a lot of useful work to do in the elaboration of what seems to be a most useful model.

John Maddox

CYSTIC FIBROSIS

Steady steps lead to the gene

P. N. Goodfellow

IT WOULD be difficult to overstate the importance of the cloning of the cystic fibrosis gene (*CF*) which was reported in a series of papers last week in *Science*[1-3], and which is the successful culmination of a collaboration between the laboratories of L.-C. Tsui at the Hospital for Sick Children, Toronto, F.S. Collins at the University of Michigan and J.R. Riordan, at the University of Toronto.

Cystic fibrosis is a genetic disease that drastically reduces the quality of life and curtails life expectancy In caucasian populations, 1 individual in 20 is a carrier of the defective gene. Consequently, in Britain, the birth incidence for this recessive disease is about 1 in 2,000. Afflicted individuals produce large amounts of thick mucus in their lung epithelia. This blocks the airways and promotes bacterial infection Over the years, chronic lung infection results in gradual lung destruction and death is usually from this cause. Abnormal mucus production by epithelia elsewhere in the body may also cause complications, including the blockage of exocrine secretion. Treatments are designed to ameliorate symptoms and to prevent lung infection, cure is not possible[4].

At the cellular level, previous research has identified an abnormality in ion transport in epithelial cells of cystic fibrosis patients[5]. The relationship between the ion transport defect and the underlying cause of cystic fibrosis is not known, nor is it clear what the relationship is between the ion-transport abnormalities and the production of thick mucus.

Two general strategies have been applied to isolating the *CF* gene. Theoretically, it should be possible to use physiological, pharmacological and biochemical methods to identify the defective protein in cells of cystic fibrosis patients. While making steady progress, this approach has been hindered by a general paucity of information about the structure and regulation of ion channels and associated molecules. The second strategy was to prove more fruitful; several groups, including the Tsui–Collins collaboration, have applied the package of molecular genetic techniques commonly referred to as reverse genetics. The principles are simple and have been propounded in these columns previously[6]. In brief, the target gene is first located on a chromosome by linkage analysis in family studies. Further genetic markers are sought that closely flank the target gene on both sides. Sequentially cloning all the sequences between flanking markers, a process known as chromosomal walking, must result in the cloning of the required gene. This leaves the final problem, which is to recognize the target gene in the cloned sequences. The cloning of the *CF* gene closely followed this pathway.

In 1985, the first linkage between the *CF* gene and a genetic marker was found. Unfortunately, this linkage was to a gene (*PON*, encoding the polymorphic enzyme paraoxonase) that itself had not been located in the genome[7]. Soon afterwards, Tsui *et al* localized *CF* to chromosome 7 by establishing linkage between *CF* and the random DNA segment *D7S15* derived from that chromosome[8]. The position on chromosome 7 was further refined by the discovery of the closely linked markers *MET* and *D7S8*, described by the groups of R. White and R. Williamson, respectively[9,10] Fortunately, *MET* and *D7S8* flanked the *CF* gene, thus defining a target region of approximately $1–2\times10^6$ base pairs in which it must lie A chromosomal walk of this size is a massive undertaking. Therefore an attempt was made further to reduce the target size by screening for additional markers that mapped between *MET* and *D7S8*. Two were found — *D78S122* and *D7S340*. A third marker, *IRP*, isolated by Estivill *et al.* was originally proposed to be a candidate for the *CF* gene[11]. But although it mapped very close to the *CF* gene, it became clear that it is distinct.

Armed with these probes, Tsui, Collins and colleagues initiated a series of bi-directional chromosome walks by isolating clones containing overlapping sequences derived from the target region. The efficiency of the walk was boosted by using chromosome jumping, a technique pioneered by Collins. Jumping serves two purposes it allows the rapid production of additional starting points for chromosomal walks and prevents the walks from being stalled by unclonable sequences.

In all, about $2–3\times10^5$ base pairs of genomic sequence were cloned before the (5′) end of the candidate *CF* gene was found. Several walks of this magnitude have been reported previously; nevertheless, few groups yet have the capacity for performing such a walk, and it is not easy — as testified by the description by Rommens *et al.*[1] of several unstable and unclonable sequences. As sequences were accumulated in the target region the end game was reached: it remained to identify the *CF* gene and to prove its causality for cystic fibrosis.

As Rommens *et al.* comment, there is no single or guaranteed route to gene identification. Experience gained from isolating other human genes, however, suggests that cross-species hybridization is a powerful approach. This provided the first clue for the existence of the candidate *CF* gene; fortunately, although the cross-hybridization to rodent DNA was weak, bovine DNA proved better. Eventually, after screening seven different libraries with the bovine cross-reacting genomic clone, a single cDNA clone was isolated. Even at this point the problems were not over, Riordan *et al.*[2] had to isolate over 20 cDNA clones to assemble a complete open reading frame and many of these clones contained extraneous sequences or unspliced introns. Finally, it was necessary to use anchored polymerase chain reaction techniques to clone the untranslated sequences at either end of the coding sequence. These clones provided the tools to check the tissue distribution of the mRNA and to obtain the deduced amino-acid sequence of the candidate gene.

Was it the genuine *CF* gene? The tissue distribution of its mRNA was consistent with that predicted by the pathogenesis of cystic fibrosis. Also consistent was that the deduced amino-acid sequence indicated that the gene product is related to membrane transport proteins — for more on which, see opposite. This, and the need to avoid confusion with previous candidate *CF* genes, leads Riordan *et al.* to suggest that the protein is called cystic fibrosis transmembrane regulator (CFTR); it is to be hoped that the name has predicted the true function.

The best evidence that the *CF* gene had been isolated was obtained from correlating sequence data with genetic analysis[2,3]. The major difficulty here was that there is strong linkage disequilibrium across the region where the *CF* gene is located. This means that it is difficult to distinguish between *CF* mutations and polymorphic variation showing very strong allelic association with the *CF* mutation. Nevertheless, about 70 per cent of the mutations in cystic fibrosis patients were associated with a deletion of a specific phenylalanine residue (ΔF_{508}) Moreover, this deletion was not found on chromosomes that did not carry a defective *CF* gene, even if they carried the same allele distribution as those that did The allelic associations of the 30 per cent of mutations not due to ΔF_{508} suggests they are a heterogeneous group[3]. Final proof that the gene for CFTR corresponds to the *CF* gene will come if it can be shown in cell physiology experiments that the gene restores normal function to cystic fibrosis cells; the same system could be used to test the ΔF_{508} deletion.

The implications of this research are profound; there will be large spin offs in basic biology, especially in cell physiology, but the largest impact will be medical. A rough estimate would suggest that worldwide about 5,000 people die each year of cystic fibrosis. If the ΔF_{508} mutation alone is the major cause of the disease, detection of the 1 in 20 members of the population that carry the mutation could contribute

to the prevention of many of these deaths in the future. At present, prenatal diagnosis contributes to the avoidance of new cases of cystic fibrosis in families with the disease; the detection of carriers would make it possible to avoid the conception or birth of many currently unavoidable cases. I disagree with the sentiments of Kerem *et al.*[1], who suggest waiting until all the mutations have been identified — carrier testing is worthwhile now.

Finally, there is the hope that knowledge of the structure and function of CFTR will lead to the design of rational approaches for treating cystic fibrosis. That hope, however, should be tempered with the lesson of sickle cell anaemia: molecular advances do not always lead to molecular cures[12]. □

Protein joins transport family

Chris Higgins

OBTAINING a gene sequence is, in itself, not always especially informative. *CF* is clearly an exception[2], its sequence giving a strong indication of the biochemical nature of the cystic fibrosis defect. The CFTR protein that *CF* encodes shares considerable organizational and sequence similarities with a family of ATP-dependent transport systems that have been extensively studied in bacterial cells and which have more recently been shown to have eukaryotic counterparts (see ref. 13). The best characterized members of this family are the bacterial transporters referred to as the periplasmic or binding-protein-dependent transport systems. Over 20 such systems have been identified, each specific for a different substrate (such as an amino acid, sugar, peptide or inorganic ion)[14]. Transport requires the function of a 'periplasmic binding protein' (hence the family name) that delivers substrates to a complex of membrane proteins that mediate substrate translocation across the membrane.

The 'basic' membrane complex consists of four protein subunits (although there are variations on this theme), two of which are highly hydrophobic and span the membrane five or six times, and two of which are hydrophilic and associated with the cytoplasmic face of the membrane. The hydrophilic subunits share considerable amino-acid sequence similarity over much of their length. The conserved sequences include a potential ATP-binding site, and several of the proteins, indeed, bind ATP[15,16]. Although none of the purified proteins has yet been shown to hydrolyse ATP, there seems little doubt that they do and stoichiometric ATP hydrolysis concomitant with transport has been demonstrated[17].

Schematic model of CFTR, modified from ref. 2. The two membrane-spanning subunits are joined by a nucleotide(ATP)-binding fold (NBF) and the large R subunit. The other NBF is at the carboxy(C)-terminus.

Several eukaryotic counterparts to these bacterial transporters have been identified. All differ from the bacterial transporters in that the individual protein subunits are combined into a single multi-domain polypeptide, but the overall organization and amino-acid sequences are strongly conserved. The first eukaryotic example to be found was the MDR protein, or P-glycoprotein, which is responsible for multidrug resistance in tumours. The protein functions as a transporter, pumping drugs out of cells. The CQR protein responsible for chloroquine resistance in the malarial parasite turns out to be closely related to MDR[18], as is the product of the *STE6* locus of yeast, which mediates export of **a**-factor mating pheromone from the cell[19,20].

It is to this widespread group of eukaryotic transporters that CFTR, the product of the *CF* gene, belongs. In its overall structure, CFTR is very similar to the other transport systems, having two hydrophobic domains, which comprise potential membrane-spanning helices, and two ATP-binding domains (see figure). Furthermore, CFTR includes an additional, large cytoplasmic domain (R in the figure) which, based on consensus phosphorylation sites for protein kinase C and cAMP-dependent protein kinase, probably serves a regulatory role. Thus there seems little doubt that CFTR is a transport system, but for what?

It has become clear that cystic fibrosis patients show altered chloride transport across epithelia and that this is the root cause of the most severe clinical symptom — decreased fluid secretion and accumulation of dehydrated mucus in the bronchial tubes. Furthermore, this chloride channel is subject to complex regulation, only now being unravelled. Channel activity is increased by cAMP-dependent protein kinase in normal subjects but not in patients; activation by protein kinase C also seems to be defective in patients[21–24]. Biochemically it is unclear whether the primary defect is in the chloride channel or in another component of the complex regulatory network. The similarity of CFTR to other membrane transporters strongly suggests that it is part of the chloride transporter, and hence it is this pump that is altered in cystic fibrosis patients. But this has yet to be demonstrated. It may be significant that the predicted molecular mass of CFTR is rather different from that of functional chloride channels recently isolated from epithelia[25].

Over 60 per cent of cystic fibrosis patients seem to have the same mutation, a deletion of three nucleotides, removing a single phenylalanine residue from CFTR[2]. This amino acid is in one of the highly conserved ATP-binding domains of the protein but is not one of the supposedly crucial amino acids in the 'core' site[16]. Does the mutation completely destroy the function of the CFTR or is it a specific missense mutation that alters the protein's activity? There is support for the latter view as patients' regulation of chloride flux is altered rather than absent.

If the cystic fibrosis phenotype involves protein misfunction, not loss of function, there is a better chance of devising a corrective treatment for the disease; it would be hard to replace an absent transport protein, but it may be possible to modulate the activity of one that is perturbed. In what way might such a missense mutation affect the activity of the CFTR protein? One possibility is a subtle effect on the coupling of ATP hydrolysis to the transport process. An understanding of this will probably require determination of the three-dimensional structure of these sites, not impossible given recent progress on bacterial transport proteins. Their ATP-binding domains are so similar to CFTR that there is no doubt that they provide an important structural model. □

CLIMATE CHANGE

Wetter clouds dampen global greenhouse warming

Tony Slingo

VARIATIONS in cloudiness can significantly affect the Earth's radiation budget — the absorbed solar energy and the thermal energy radiated back to space[1]. This conclusion is supported by various modelling studies of the 'greenhouse' effects of increased CO_2 concentrations[2–4]. In these studies, the CO_2 forcing induces changes in the cloud coverage and liquid-water content, which alter the radiation budget further and thus modify the original perturbation. On page 132 of this issue[5], Mitchell *et al.* add a new twist to the story, showing how changes in the relative amounts of ice-crystal and water-drop clouds substantially reduce the sensitivity of their model to changes in concentration of CO_2. Indeed, it is becoming apparent that uncertainties in the treatment of clouds severely undermine model prediction of climate.

Mitchell *et al.* used various versions of the UK Meteorological Office atmospheric general circulation model[6] coupled to a 50-m ocean mixed layer[7]. Replacing the standard cloud prediction scheme based on relative humidity by a more sophisticated prescription including liquid water and ice virtually halves the average equilibrium surface warming due to doubled CO_2 — from 5.2 K to 2.7 K. They argue that this spectacular sensitivity to details of the cloud scheme is caused by the replacement of ice clouds by water clouds near the freezing level. In the new cloud scheme, the fall-speed assumed for water drops is much smaller than that for ice crystals, so that liquid-water clouds can dissipate more slowly than ice clouds. According to Mitchell *et al*, this leads to the predicted relative increase in water clouds near the freezing level, which consequently reduces the amount of solar energy absorbed in the system (more is reflected back into space) and hence gives a smaller warming. When, in addition, cloud radiative properties are allowed to depend on the liquid-water content of clouds, the surface warming drops still further, to only 1.9 K.

The strong dependence of the magnitude of cloud feedback in this work on the details of the model parallels results presented recently[8] by a large *ad hoc* group (including Mitchell and myself) led by Robert Cess of the State University of New York. We compared 14 general circulation models and found a three-fold variation in global climate sensitivity, caused largely by differences in the cloud feedbacks. The models disagreed not only as to the magnitude but also the sign of the net cloud feedback. For this reason, it is clear that uncertainty in how to formulate clouds represents a formidable obstacle to reliable climate prediction.

This underlines the continuing need for physical parameterizations to be compared with results from field studies. This is particularly important now that models are becoming increasingly complex. Mitchell *et al* argue that the assumptions in their model are 'at least qualitatively realistic', but if climate change simulations are to be believable, then all parts of a model must be validated quantitatively, and important processes that are ignored must be identified. Of particular relevance to the cloud problem is the FIRE programme (first regional experiment of the international satellite cloud climatology project), both in its stratocumulus[9] and cirrus[10] field phases. Several papers are in preparation that highlight the complexity of the mesoscale dynamical structure of cirrus, so that the fall-speed of ice crystals is only part of the story. It is also interesting that two cases of highly supercooled liquid-water altostratus clouds at temperatures around −30 °C were observed (A.J. Heymsfield *et al.*, personal communication), which suggests that the transition from water to ice clouds is more subtle than Mitchell *et al.* assumed for their model.

The substantial sensitivity of climate models to the details of their formulation, and the fact that 14 models give 14 different answers for the cloud feedback, show that we are far from the goal of accurate predictions of future climate change. Sensitivity studies such as that reported by Mitchell *et al.* and comparisons between models as done by Cess *et al.* are now the bread and butter of climate modelling. But at the present rate of progress, it will be several years before reliable predictions of global and regional climate change are available from the models. That underlines the need for comprehensive monitoring that is capable of unravelling the climate change signal from the noise and of providing enough data on the state of the atmosphere, the Earth's radiation budget and clouds for the feedbacks to be determined by observation. Such an analysis may well yield the fifteenth answer but at least it will have come from the real world and will permit a much needed test of the models. □

ECOLOGY

Just proportions in food webs

Joel E. Cohen

IN FOOD webs of natural communities with varying numbers of species, the number of green plants and other species that consume no prey in the web (basal species) is nearly proportional, on average, to the number of species that have both predators and prey in the web (intermediate species), according to studies reported over the past dozen years[1–4]. Empirical rules[5,6] of that type describe structural or anatomical properties of food webs. An important question in community ecology is whether parallel regularities exist in the way in which food webs function[7,8]. On page 142 of this issue[9], McNaughton *et al.* report remarkable regularities in measures of food web function. Their findings indicate the existence of a physiology of food webs that generalizes across natural communities. Their report opens up the distant, but highly attractive, prospect of linking the previously known structural regularities with new functional patterns.

McNaughton *et al.* show that the biomass, consumption and net secondary productivity (NSP) of herbivores are all related to the net above-ground primary productivity (NAP) of a natural habitat by simple power laws. Particularly striking is that the exponent of the power law that relates NSP to NAP is not significantly different from 1: to a first approximation, NSP and NAP are directly proportional. In effect, the energy converted into herbivores per square metre of surface area per year is, on average, about one-thousandth of the energy that is converted into plants per square metre of surface area per year. The ecological energy pyramid has a much larger base than second storey.

This proportionality would be a triviality if secondary productivity were passively controlled and limited by primary productivity. But this trickle-down view of

community structure ignores evidence that herbivores not only depend on, but strongly influence, the plants they eat. In *The Origin of Species*, Darwin reported that, on a small cleared plot, he "marked all the seedlings of our native weeds as they came up, and out of 357 no less than 295 were destroyed, chiefly by slugs and insects." More recent studies show clearly that the feedback effects of herbivores on plant populations are both negative[10] and positive[11]. In the light of these studies, it is far from an expected finding that the complex interplays between plants and herbivores should yield a simple proportionality between NAP and NSP. Moreover, the constant of proportionality, one-thousandth, is far less than might have been guessed from widely quoted ecological efficiencies of the order of 10–20 per cent. Nor would the trickle-down theory explain why consumption by herbivores rises as the square of net foliage production, as McNaughton *et al.* find.

If studies of food-web structure demonstrate a rough proportionality between the numbers of basal and intermediate species (trophic species, really, since biological species with identical predator species and identical prey species are counted as a single unit), and if future studies of food-web function confirm the finding of McNaughton *et al.* that NSP and NAP are proportional, the next problem, and opportunity, is to relate the two proportionalities. In the 35 studies where NSP and NAP were both measured directly, are the numbers of basal trophic species proportional to the numbers of herbivore trophic species? What is the relation between primary or secondary productivity and the diversity of biological and trophic species in these studies? Stay tuned!

But as Mark Twain advised a young reporter: first get your facts straight, then you can distort 'em. McNaughton *et al.* acknowledge that their findings would be considerably strengthened by more data from tropical forests and other structurally complex systems. At present, their results rely heavily on structurally simple vegetation such as grassland and tundra. Moreover, the wide scatter of the assembled data with respect to the log–log linear regression proposed to describe them brings to mind the statistical maxim that, on log–log coordinates, even an elephant looks like a straight line. The report of McNaughton *et al.* does not have all the answers, but it has some and, better still, it raises important new questions.

Both the structural and the functional proportionalities found in food webs are purely descriptive Though a model exists that explains much of food-web structure[5,12], it too is phenomenological; and there is no hint of a mechanistic explanation for the observed patterns in the report of McNaughton *et al.*. But ecology is a very young science. A backward glance to the early stages of other, now maturer, sciences shows the tremendous power of empirical proportionalities. Joseph Louis Proust proved that elements combine in definite proportions by weight when they form chemical compounds (the law of definite composition), laying a cornerstone of the empirical support for the atomic theory[13]. Gregor Mendel found fixed proportions of different phenotypes in offspring in his experiments on plant breeding; his explanation in terms of genes was phenomenological. Erwin Chargaff's discovery that the concentration of adenine equals that of thymine and that the concentration of guanine equals that of cytosine in DNA from various sources was one of the chief clues to Watson and Crick's solution of DNA structure. Time will reveal the scientific consequences of the new proportionalities in food-web structure and function. The possibilities are exciting. □

ASTRONOMY

Dark secrets of a giant galaxy

M. G. Edmunds

THE discovery of a single exceptional object can radically affect accepted ideas. If a single man more than 60 feet in height were suddenly to be found in, say, Outer Mongolia there would no doubt be an urgent re-examination of current opinion in human genetics. Although the sizes of galaxies span a much greater range than those of people, recently published observations by C. Impey & G. Bothun (*Astrophys. J.* **341**, 89–104; 1989) of an exceptionally large galaxy, suggest a need for careful reappraisal of current opinons on the formation and evolution of spiral galaxies.

The exceptional object is Malin 1, discovered by chance two years ago and named after David Malin, who pioneered the photographic amplification technique crucial in its detection (G. D. Bothun, C. Impey, D. F. Malin & J. R. Mould *Astr. J.* **94**, 23–29; 1987). Amplification was necessary because the surface brightness — the brightness per unit area — of the galaxy on the sky is very small: when fighting against the light of the night sky (which is not nearly as dark as it appears to the naked eye), an extended object of low surface brightness is hard to find Indeed, recognition of Malin 1 was possible only because it has a fairly bright central region (bulge component and nucleus) showing a few weak emission lines. These could be used to measure a redshift, so giving a distance and allowing the precise tuning of radio telescopes to investigate the hydrogen content.

What emerged was a galaxy with over three times as much neutral hydrogen as any galaxy previously reported, and with an extraordinary physical size. The dim disk has an exponential scale length (the length over which the brightness decreases by a factor of e) of at least 55 kiloparsecs (kpc). The total extent in neutral hydrogen is greater than 240 kpc. The exponential scale length should be compared with that of our own Galaxy (5 kpc) and Andromeda (6 kpc), themselves fairly large relative to typical spirals, whose scale lengths are around 2 kpc.

Despite its size, it was the faintness of the disk that had made Malin 1 inconspicuous. Two questions obviously spring to mind. First, what effect does meagre surface brightness — and, by direct implication, low physical density of material — have on the evolution of a galaxy, and second, are there many more such galaxies out there?

The new spectroscopic observations, by Impey and Bothun, of Malin 1 show that the central bulge component is not particularly unusual. It displays the features expected of an old and evolved stellar population, much as one might find in an average spiral, with some evidence of continuing star formation. It is the disk that is unusual. This prompts the authors to raise the question whether the bulge and disk may have been essentially independent of each other since they were formed. The density of the disk is so low that it is near to a theoretical limit for the growth of instabilities which could lead to star formation.

So the disk may have been just sitting there, with little happening, since it formed.

Malin 1 is situated in a region of comparatively empty space, and there may have been no encounters with other galaxies to disturb its fragile, mainly gaseous, disk. Alternatively, the disk could be an addition, perhaps recently accreted by the central galaxy from the intergalactic medium and not yet sufficiently dense to have formed many stars.

The first idea is attractive because it agrees with several speculations about the origin of some of the absorption lines due to the Lyman-α series of hydrogen that are a feature of the measured spectra of some distant quasars (see, for example, A. M. Wolfe, D. A. Turnshek, H. E. Smith & R. D. Cohen *Astrophys. J. Suppl.* **61**, 249–304; 1986). The strength of the absorption lines indicates high column-densities of neutral hydrogen in the absorbing objects lying between us and the quasars. Indeed, the measurements suggest that the properties of those objects match those of disks of low surface brightness, such as Malin 1.

What the quasar measurements show is that absorbing objects with strong Lyman-α lines are reasonably common at redshifts of about 2. If they are indeed disks on the pattern of Malin 1, which is relatively nearby, the implication is that it must be possible for disks of this kind to remain stable for periods of time corresponding to the interval between redshift 2 and (almost) the present. That suggests that large tenuous gas disks may still be fairly numerous — indeed, Impey and Bothun suggest that it would be consistent with their observations that the mass of disks such as Malin 1, still mostly unobserved, might amount to as much as half the mass of the known galaxies.

But that constrains galactic evolution to a fairly tight schedule. If a substantial proportion of the disks have remained unchanged since redshift 2, it is not easy to understand how there could have been time enough for them to have been formed in large numbers by that time Although the interval in which galaxies were formed remains uncertain, it was probably between redshifts 10 and 3. According to Wolfe *et al.*, that implies the disks would only have been between 1,000 and 4,000 million years old by the time they are observed in the quasar absorption spectra at redshift 2. This is the kind of timescale now used in models of the formation of galaxies by the collapse of gas clouds.

It will be important if other extended disks of low-surface brightness like Malin 1 can be found, to show that galaxies *can* have well-developed disks at an early stage. (Such observations would also show that Malin 1 is not just a rare, late developer.) The importance of such objects for theories of the evolution of spiral galaxies would be in increasing the ranges of both the physical size and the evolutionary rates to be explained. They may show that spiral galaxies form quickly as individual gaseous-disk systems, but that the subsequent rate of evolution (as judged by how fast the gas turns into stars) varies much more than prevously realized, depending critically on parameters such as the denisty of material.

Although there are other large galaxies with low surface brightness, Malin 1 is by far the largest known. All have active nuclei, which is probably why they have been identified. It is not easy to predict how many more await discovery, especially if they are inconspicuous without bright centres. Even nearby systems could have escaped notice. Impey and Bothun point out that, because of the characteristics of radio telescopes, Malin 1 might not have been recognized had it been as close as the Virgo Cluster, behind which it was found.

Nearby examples should be eagerly sought It would be invaluable to learn more about their properties, particularly the age and nature of the stellar population in the disks and their total masses and mass distributions from rotation curves. But even for nearby examples, the observational difficulties will be very great because the surface brightness (which is what essentially determines the quality of observations for an extended object) does not change with distance, and it will also be (by definition) low for nearby examples of these galaxies. □

LIPOPROTEIN-REMNANT RECEPTORS

Second receptor verified?

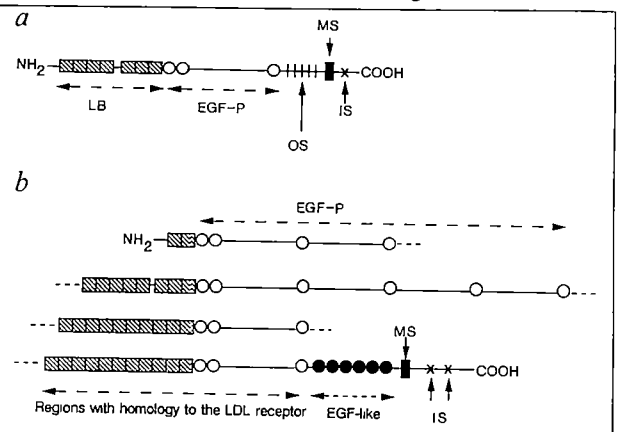
Anne K. Soutar

CHYLOMICRON remnants, the lipoprotein by-products of dietary fat absorption and transport, are rapidly and efficiently cleared from the circulation by a mechanism located exclusively in the liver[1], but how? Although the receptor for low-density lipoprotein (LDL) recognizes chylomicron remnants and could have that function[2], there must be a second genetically distinct mechanism to account for the apparently normal clearance of chylomicron remnants in patients with familial hypercholesterolaemia[3] (FH) and in WHHL rabbits[4], both of which lack functional LDL receptors. Now, two papers, one by Beisiegel *et al.* on page 162 of this issue[5] and another from Brown and Goldstein's laboratory in Dallas[6] go some way to strengthen the belief that the latest candidate for this role — LRP, otherwise LDL-receptor-related protein — may indeed be the second receptor But the issue is not yet settled, and LRP may have other interesting functions as well, or even instead.

The complementary DNA of LRP was found[7] last year by screening a mouse lymphocyte cDNA library for sequences corresponding to the highly conserved cysteine-rich motif of the ligand-binding domain of the LDL receptor, also present in the terminal components of complement. The predicted amino-acid sequence of one selected clone turned out to be quite remarkably similar to that of the LDL receptor[8] (see figure), raising the possibility that it might be the previously elusive chylomicron-remnant receptor. The homology also suggested absorbing questions about its evolutionary relationships with other proteins, notably the LDL receptor[9] itself and the precursor of epidermal growth factor. But it is too soon to conclude that LRP is indeed the chylomicron-remnant receptor molecule.

Uptake experiments *in vivo* and in perfused liver show that there are two functional features that should distinguish the chylomicron-remnant receptor from the LDL receptor: it should recognize lipoproteins that contain apoE, but not those such as LDL that contain only apoB; and its level of expression should not be influenced by intracellular cholesterol accumulation. Otherwise, the receptor should resemble the LDL receptor in its location on the surfaces of liver cells and in its capacity to mediate endocytosis and lysosomal degradation of whole lipoprotein particles.

The new paper by Beisiegel *et al.* is the result of collaboration between the Hamburg group and Herz and Stanley at the EMBL at Heidelberg, who originally cloned LRP It provides fairly convincing evidence that LRP is a cell-surface protein that binds apoE. This they have done by the use of phospholipid liposomes complexed with apoE that has been chemically modified with a crosslinking agent capable of being photoactivated. They have shown that if these liposomes are incubated either with HepG2 cells or with isolated human liver membranes, the crosslinker labels a single-membrane protein of large molecular weight that is immunologically indistinguishable from LRP



But these observations alone do not, of course, establish identity. Because the liposomes used are by no means identical with authentic chylomicron remnants, whose use would have complicated the study because they contain apoB and apoC as well as apoE, it was important for the authors to demonstrate that there is competition for binding sites between the artificial liposomes and native lipoproteins containing apoE. However, they

have not further investigated the specificity of the receptor binding. In particular, they have not applied the essential test of showing that the receptor does not bind LDL, but it would also have been interesting to know whether lactoferrin, which specifically inhibits[10] hepatic uptake of chylomicron remnants but not LDL, interferes with apoE binding to LRP. And not everybody will agree with the authors' claim that the equal affinity for LRP of apoE$_2$ (an isoform of apoE that does not bind to the LDL receptor) and the other isoforms of apoE is further evidence that LRP is the chylomicron-remnant receptor.

Evidence of a different nature, from Brown and Goldstein's group[6] at Dallas (now joined by Herz from Heidelberg), shows that in skin fibroblasts from an FH patient unable to synthesize LDL receptor molecules, LRP mediates the uptake and lysosomal degradation of cholesteryl esters derived from lipoproteins enriched in apoE The authors have not been able to demonstrate that LRP directly determines either the binding or degradation of radiolabelled lipoproteins, but instead have followed changes in the incorporation of ^{14}C-labelled oleate into cholesteryl esters. The assumption is that, if the rate of incorporation is greater when cells are incubated with lipoprotein, the lipoproteins themselves must have been subjected to endocytosis mediated by receptors and to degradation by lysosomes, with the release of free cholesterol.

This argument is not watertight, but the conclusion that lysosomes are involved is supported by the observed inhibition of oleate incorporation by chloroquine. A further difficulty is that it has not been possible to demonstrate these changes in oleate incorporation with native lipoproteins. Although the authors worked with rabbit β-VLDL (very-low-density lipoprotein), which accumulates in the plasma of rabbits fed cholesterol, they were unable to demonstrate LRP-dependent stimulation of oleate incorporation unless they pre-incubated the β-VLDL with exogenous apoE before adding it to the cells. This is surprising, because β-VLDL is already apoE rich and binds with high affinity to the LDL receptor. But changes of oleate incorporation were suppressed by pre-incubating the cells with anti-LRP polyclonal IgG, indicating that intracellular events are influenced by some interaction between apoE and LRP even if the evidence is not compelling that LRP mediates endocytosis of the whole lipoprotein.

Further circumstantial evidence that LRP is indeed the chylomicron-remnant receptor comes from the structure of the gene and its genetic environment. The promoter region of the LRP gene does not contain a sterol regulatory element of the kind associated with the LDL receptor (as well as with the genes of HMG CoA reductase and HMG CoA synthase), which agrees with the observation that the expression of LRP is unaffected by sterols[11]. Yet the most obvious difficulty in equating LRP and the chylomicron-remnant receptor remains its tissue distribution. The protein is expressed in several tissues and is, for example, as abundant in brain and lung as in liver[4]. Yet there is no evidence that chylomicron remnants are degraded anywhere but in the liver. It would be surprising if LRP had no function in other tissues.

Similarity between the predicted structures of *a*, the low-density lipoprotein (LDL) receptor[8], and *b*, the LDL-receptor-related protein[7] (LRP). The ligand-binding domain (LB) of the LDL-receptor protein (*a*) comprises seven copies of a highly conserved cysteine-rich motif that is also found in the terminal complement components. Adjacent to this is a region (EGF-P) with extensive homology to the epidermal-growth-factor precursor that also contains three copies of a second cysteine-rich motif. The linear structure of LRP (*b*) is arranged to demonstrate its homology with the LDL receptor. The predicted amino-acid sequence shows that its extracellular domain contains four copies of the binding and EGF-precursor-homology domains of the LDL-receptor protein, each containing multiple copies of the two types of cysteine-rich motif It also has a membrane-spanning domain (MS), and its cytoplasmic COOH-terminal tail contains two copies of a short sequence of amino acids that have been identified as the signal for internalization (IS) of the LDL-receptor protein[7]. In LRP, the extracellular O-linked sugar domain (OS) adjacent to the membrane-spanning region in the LDL-receptor is replaced by six copies of a third cysteine-rich motif that has high homology to EGF

Meanwhile Stanley, who has moved to the Heart Research Institute in Sydney, has continued to explore other biological functions of LRP as well as its putative role as a remnant receptor. He reported at a recent meeting* that, for such a large molecule, LRP turns over rapidly in cultured cells and that it differs from the LDL receptor in not recycling to the surface after internalization. Interestingly, the short amino-acid sequence in the cytoplasmic tail of the LDL receptor required for clustering and endocytosis[9] serves the same function in LRP. But there is a second copy of this sequence in the cytoplasmic tail of LRP and it has been shown (by substituting the cytoplasmic tail of LRP for the corresponding structure of haemagluttinin A in the influenza virus) that the presence of the second copy is both necessary and sufficient to ensure rapid degradation of the protein. Plainly we shall learn as much about the regulation of intracellular protein traffic from LRP as we have done from the LDL receptor.

But if LRP proves not to be the chylomicron-remnant receptor, what can be its function? Stanley and his colleagues offer[11] as a clue the observation that an early degradation product of LRP is a protein cluster of relative molecular mass of roughly 90,000, which is consistent with the notion that the four LDL-receptor-like domains have been specifically cleaved away, leaving only the membrane-bound fragments of the molecule which, it turns out, are remarkably homologous (see figure) with the precursor of epidermal growth factor. This truncated LRP could thus serve to release growth factors, but Stanley (personal communication) also believes that, because LRP is found chiefly in cells synthesizing apoE[12], its function may be related to the secretion of this lipoprotein. If one also recalls that apoE synthesis is increased in regenerating nerve fibres[12], the prospects are that the functions of LRP will extend far beyond that of simply binding chylomicron remnants □

NATURAL KILLER CELLS

A primitive immune system

Charles A. Janeway

THE first great controversy in immunology pitted Metchnikov and the cellularists against Robert Koch and the humoralists[1]. One consequence of the subsequent humoralist victory was the focus of immunology on the chemistry of antibodies and the abandonment of inquiry into the cells that mediate host defence. Interest in some of these cells was revived by Burnet's clonal selection theory of antibody formation[2] and by Gowans's discovery that lymphocytes mediate all specific immune responses[3]. These milestones in immunology directed attention toward the specificity of antigen recognition, and away from Metchnikov's original interest in primitive host cellular responses to infection.

As our understanding of specific antigen recognition has exploded, culminating in the discovery of seven families of rearranging genes encoding T- and B-lymphocyte receptors[4], one can start to ask a more metchnikovian question: did immunological effector mechanisms evolve after the sophisticated recognition systems that now trigger them, or are the recognition systems recent additions to pre-existing, non-clonal systems of host defence[5]? Natural killer (NK) cells — lymphocytes (non-T, non-B) that can kill certain tumour cells[6,7] — may constitute such a system. In demonstrating the presence of the invariant ζ-chain component of the T-cell receptor in NK cells, the paper of Anderson *et al.* on page 159 of this issue[8], may help to answer the question.

Host defence against infection occurs in three phases in mammals: innate resistance that is not inducible; an early, inducible phase that is largely antigen-non-specific; and a late, T-cell dependent phase that is highly antigen specific and generates immunological memory[9]. NK cells participate in the innate[10] and early, interferon-inducible[11,12] phases of the immune response to viral infection (see table below).

Viruses parasitize host cells, where they replicate and produce new virions that spread the infection. The immune response blocks viral spread by making specific neutralizing antibodies and specific (class I MHC-restricted) cytolytic T cells that kill virus-infected cells. Although NK cells are identified by their ability to kill certain tumour cells without prior immunization[6,7], recent evidence has suggested a more important role of NK cells in host defence against viral infection[13]. This is supported by the discovery of an individual whose only demonstrable immunological defect was the absence of NK cells[10]. The early phases of herpes virus infections were markedly exaggerated in this patient and would have been fatal without anti-viral and supportive therapy, although she ultimately made antibody and cytolytic T-cell responses that cleared the infections.

How does an NK cell that lacks a clonally distributed receptor know which target cell to attack? The answer to this question remains shrouded in mystery; indeed, it may be the wrong question. Rather, a single NK cell may have multiple recognitive mechanisms. Thus, NK cells may function as a back-up defence mechanism for cytolytic T cells by destroying cells that lack class I MHC molecules[14]; they have Fc receptors that allow them to kill antibody-coated target cells[15]; they clearly kill certain virus-infected cells[10,13]; they appear to regulate haemopoiesis (through recognition of structures mapping between H-2S and H-2D in the MHC of mice)[16]; and they can directly kill certain bacteria[17].

That NK cells and cytolytic T cells share cytolytic effector mechanisms suggests that the NK cell is an evolutionary forerunner of the cytolytic T cell, just as the 'alternative' pathway of complement activation is likely to be a forerunner of the 'classical' pathway triggered by specific antibody (note the bias in the naming of the 'classical' pathway by humoralists). It seems likely that the host defence systems of primitive organisms consisted of effector cells like the NK cell with multiple non-clonally distributed recognitive mechanisms. Primitive immune systems would be expected to have had few cells, so the effector cells must have been multi-specific. The acquisition by an NK cell of a clonally distributed receptor capable of fine discrimination between self and non-self might have been sufficient to make it a cytolytic T cell. Clonally distributed receptors allow an immune system to recognize infection by any virus and the development of immunological memory through clonal selection.

But the T-cell receptor is not just an antigen-binding molecule. It is also the ligand-binding domain of a signal-transducing molecular complex that includes the CD3 proteins[18] and a polypeptide known as the ζ-chain[19], which is required for effective signal transduction by the T-cell receptor[20]. Homologous chains are also associated with the signal-transducing Fc_ϵ receptor of the mast cell[21]. Thus ζ-like chains may be a common component of signal transduction mechanisms in cells of haemopoietic origin.

The identification by Anderson *et al.*[8] of NK cell ζ-chains, associated with larger structures that may participate in ligand recognition, supports the idea that cytolytic T cells arose from NK-like cells by acquiring a clonally distributed T-cell receptor. Further support for this notion comes from finding NK-like cytotoxic activity in long-term cultured T-cell lines[22]. Such discoveries should help in understanding the evolution of host defence mechanisms. They could spur a reunification of the metchnikovian interest in innate immunity with the mainstream of specific recognition first championed by the humoralists. It is interesting to wonder whether progress has been speeded by the triumph of the humoralists that led to the solution of the antibody problem more than it has been impeded by the early abandonment of metchnikovian thinking. □

QUANTUM PHYSICS

Topological phase of neutrons

I. J. R. Aitchison

NOVEL experimental tests of supposedly well-understood theories are always well worthwhile, even if a big surprise is unlikely. An excellent recent example[1] is the experiment performed by physicists from the Universities of Melbourne and Missouri to check the Aharonov–Casher effect[2], which directly tests very basic aspects of both quantum mechanics and electrodynamics. This effect is a topological quantum-interference effect, of the type first clearly identified by Yakir Aharonov and David Bohm 30 years ago[3]; indeed, it is closely analogous to the example these authors gave, though there are also interesting differences. One is that the effort is much weaker; thus the new observation represents an experimental *tour de force*.

Under suitable conditions, interference effects can be observed in the scattering of all wave-like disturbances, including light. The quantum wave-like aspects of matter are clearly manifested in the case of microscopic particles such as electrons or neutrons, both of which can exhibit interference effects similar to those seen with light. The classic example is the two-slit interference effect (Fig. 1*a*), in which the lateral position of the characteristic fringes set up by two coherent beams depends only on their phase difference at the detector, and hence on the difference in length between the paths travelled by each beam.

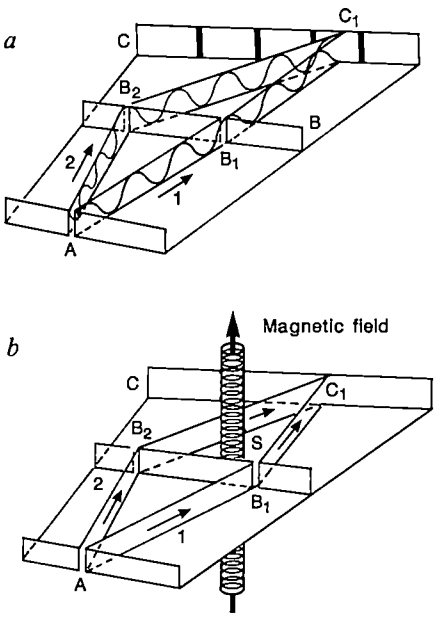

FIG. 1 *a*, The interference between the two components of a coherent wave split by a pair of slits (B_1 and B_2), is a classic demonstration of wave behaviour. The fringe maxima occur where the wave maxima coincide, and the minima occur where crest and trough cancel. Thus the lateral position depends only on the phase difference of each wave at the detector C and hence the difference between the number of cycles passed through on each path, 1 and 2, in traversing from source A to detector. *b*, The introduction of a solenoid between the two paths of charged-particle waves produces an additional phase shift — the Aharonov–Bohm effect.

The Aharonov–Bohm effect can be observed when the standard interference experiment with charged particles is modified by the introduction of a vertical, long thin solenoid between the beam paths (Fig. 1*b*). The solenoid produces a vertical magnetic field which, for all practical purposes, is confined inside the solenoid. Steps can be taken specifically to ensure that the electrons never penetrate the solenoid, so that the magnetic field cannot act upon them. Consequently, according to classical electrodynamics, they should experience no (Lorentz) force, and all phenomena observed should presumably be the same as those in the manifestly force-free arrangement of the unmodified experiment. Yet, according to quantum mechanics, there is an observable difference — namely, a lateral shift in the positions of the interference maxima. This is the Aharonov–Bohm effect.

Because the interference pattern is determined by the phase difference between beams following paths 1 and 2, it must be the case that the presence of the solenoid somehow affects this, even though the beams never enter the solenoid itself. To understand the quantum-mechanical interpretation of the phenomenon, one has to realize that the phase accrued by a quantum particle along a path traversed in one direction is precisely reversed in sign if the sense of traversal of the path is itself reversed. Thus the phase difference $\phi=\phi_1-\phi_2$ between waves that traverse paths 1 and 2 in Fig. 1*b* can also be written as $\phi_1+\phi_{(-2)}$ where $\phi_{(-2)}$ means that path 2 is reversed. The phase ϕ can now be interpreted as the total phase accrued on the closed path $AB_1C_1B_2A$. As Aharonov and Bohm noted, the essential point now is that the marriage of quantum mechanics with electrodynamics (called quantum electrodynamics) predicts that the phase accrued on a closed path is proportional to the value of the magnetic flux enclosed with the path — even if the path itself never actually enters the region of non-zero flux. All that matters is whether a closed path 'links' some magnetic flux or not

This last point is the reason the effect is now recognized as having a distinctively 'topological' nature. Topology has to do with properties that remain unchanged when shapes of things are smoothly distorted. Thus, if two circular rings are linked, they remain so as the circles are distorted into triangles, say. In the case of the Aharonov–Bohm effect, a path loop such as $AB_1C_1B_2A$ can be distorted by altering the positions of the slits B_1 and B_2, but as long as the path still links the solenoid containing the 'tube' of magnetic flux, the predicted shift in the interference pattern will be unchanged.

The effect was first observed in 1960 by Robert Chambers at the University of Bristol[4]. The interpretation of both the theory and the experiment was the subject of controversy for some years, but the question has been finally settled, to most people's satisfaction, in a recent experiment by Akira Tonomera and colleagues at the Hitachi Research Laboratories, Tokyo[5].

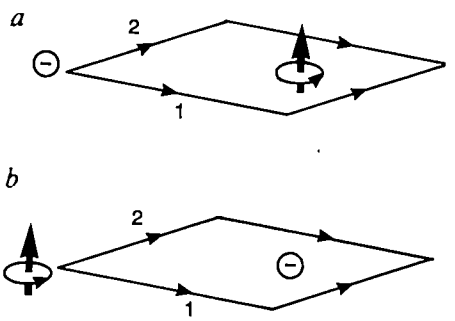

FIG 2 The equivalence of the Aharonov–Bohm effect *(a)*, in which charged-particle beams pass either side of a magnetic dipole, and the Aharonov–Casher effect *(b)*, in which the beams comprise neutral magnetic dipoles, and the linked field is due to a charge.

In 1984, Aharonov and Casher[2] proposed an interesting variant of the Aharonov–Bohm effect. Their idea can be understood as follows. The simplest possible solenoid is one with only a single loop of wire. The magnetic field due to a small current loop is the same as that of a magnetic dipole situated at its centre and aligned with its axis. (The full solenoid is equivalent to a line of such dipoles stacked on top of each other.) The corresponding Aharonov–Bohm experiment would then consist in directing beams of charged particles on either side of a magnetic dipole and observing the resulting interference pattern (Fig. 2*a*). Now reverse the roles of charge and magnetic moment, so that a beam of particles possessing a magnetic moment, but no net charge, is directed on either side of a charged particle (Fig. 2*b*). The observation of a shift in the interference pattern relative to the case in which the enclosed charge is absent, is the Aharonov–Casher effect. Of course, the single charge in Fig. 2*b* can be replaced by a line of charges stacked vertically on top of each other, thus adding a further, vertical dimension to the arrangement. ▶

The neutron is exactly such a neutral particle and, as already mentioned, neutrons can exhibit pronounced wave-like interference phenomena — which may be conveniently observed in an interferometer cut from a single crystal of silicon[6]. Thus in the new experiment of Cimmino *et al.*[1] to check the Aharonov–Casher effect, the two beam paths 1 and 2 correspond to the two 'arms' of a neutron interferometer. Recall that, being topological in nature, the predicted phase shift depends on neither the geometry of the beam paths nor the detailed configuration of the charge; all that matters is the linkage of the electric charge line by the loop corresponding to the beam path. Thus Cimmino *et al.* enhanced the effect by using a series of line charges — in fact, an electrode system, contained within the two beam paths, and creating a horizontal electric field (Fig. 3). The effect is manifested, in principle, via a small change in the counting rate at the point C when the

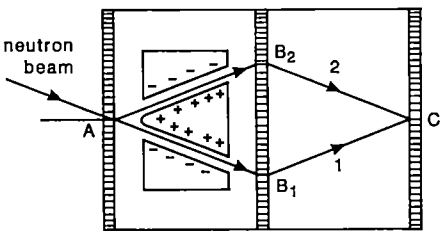

FIG. 3 Schematic of the crystalline-silicon neutron interferometer used by Cimmino *et al.* to demonstrate the Aharonov–Casher effect.

electric field is switched on, corresponding to a small shift in the intensity pattern.

A significant problem in demonstrating the Aharonov–Casher effect is that the neutron's magnetic moment is very small, so that the phase shift is predicted to be only a few milliradians; the Aharonov–Bohm shift can easily be a thousand times larger. Furthermore, the magnetic moments of the beam neutrons should all be polarized parallel to the lines of charge. But the intensity of neutron beams is weaker than that of electron beams, and weaker still if only neutrons of a definite alignment are wanted. Very long exposure times would be needed to build up reliable statistics, but this would necessitate ensuring the mechanical rigidity of the interferometer to an extraordinary degree as the normal interference pattern is determined by the difference in path length of the two arms. In fact, Cimmino *et al.* state that an uncontrolled phase drift ϕ_0 can occur, of the order of 50 mrad a day, that would completely obscure the tiny Aharonov–Casher effect.

This problem has been overcome in a highly ingenious way. For polarized neutrons, the effect of the phase drift ϕ_0 can be cancelled by reversing the polarity of the electric field and measuring the corresponding difference in the neutron counting rates. Unfortunately, this cancellation does not occur for an unpolarized neutron beam, but Cimmino *et al.* surmounted this by exploiting the fact that a phase shift can be induced if the two beams pass through different gravitational potentials[7], which can easily be achieved by tilting the whole apparatus, and adjusting the phase shift, ϕ_g, so induced to cancel ϕ_0. A further refinement was the introduction of a magnetic field over part of one of the neutron paths; this induces yet another phase shift[8], which depends on the alignment of the neutron's magnetic moment and maximizes the sensitivity of the experiment. The measured Aharonov–Casher phase is 1.46±0.35 times the predicted value, where the error is purely statistical.

This demonstration of a subtle effect is an elegant example of the experimentalist's art. It turns out that the detailed theoretical interpretation is not without interest either. Recall that in the Aharonov–Bohm effect, the particle beams never penetrate the solenoid and thus 'feel' no classical force. Do the neutrons in the new effect feel a force or not? At first sight it would seem that they do, because, according to special relativity, a particle moving with uniform velocity through an electric field also experiences an apparent magnetic field — and this can act on the neutron's magnetic moment. Indeed, this force causes a differential slowing down between the neutrons travelling along the two paths, which generates a phase shift equal to Aharonov and Casher's prediction[9].

This interpretation has been challenged by Alfred Goldhaber, who points out[10] that the total force on a neutron must include a contribution from the change in the momentum carried by the electromagnetic field at the position of the neutron; when this is included, the total force is indeed zero, provided the dipole moment of the neutron is perpendicular to the electric field. Thus the Aharonov–Casher effect, as one would expect from its close analogy with the Aharonov–Bohm effect, does seem to be genuinely force-free and topological. All the same, we can expect to see further discussion of this point, and further exploration of the possibilities opened up by the new effect. □

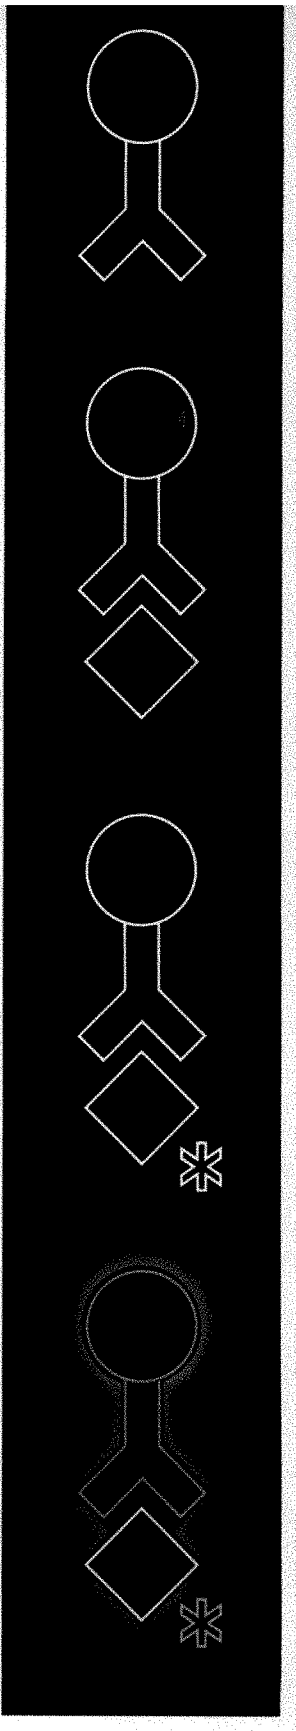
DAEDALUS

Shaking fever

MANY health physicists suspect that microwaves are hazardous, even in doses too small to cause overt heating. Perhaps, says Daedalus, they set up molecular vibrations. A big protein molecule must have many fundamental vibrations at microwave frequencies. If by chance a lot of them lay in the output-band of a powerful microwave source, all those vibrational modes would be excited simultaneously.



This by itself would not be harmful. A molecule can take a lot of vibration without falling apart. But Daedalus recalls the 'freak wave' phenomenon: many small vibrations coinciding by chance to produce a huge and damaging momentary amplitude. If many of the molecular modes of the protein all happen to stretch a particular bond, then a freak-wave coincidence phasing them all together would probably break the bond and destroy the protein.

Daedalus sees a new therapy here. For viruses, too, are big enough to have many vibrational modes in the microwave region. But, whereas proteins come in innumerable varieties each with many molecular conformations, all the particles of a particular virus must be identical, with the same vibrational modes. So DREADCO biochemists are studying selected viruses by microwave spectroscopy, to identify every vibrational mode which contributes to stretching a particular bond or set of bonds.

The vibrational analysis of a complete virus particle will be daunting indeed; but the effort will be well worthwhile. For the DREADCO team will then be able to irradiate their viral cultures with all these crucial microwave frequencies simultaneously. They will even phase the frequencies for maximum freak-wave impact. The resulting 'targeted microwave radiation' will be a splendid, highly specific, anti-viral therapy. Its heating effect need not be too great and, although it may zap the odd protein molecule by sheer chance, its general biological effect will be slight. But it will infallibly break up every virus particle of the targeted type.

The viral ills that flesh is heir to will thus be stopped in their tracks. For microwaves can penetrate the entire body. Even if the chosen virus hides inside the cells of its victim, where antibodies cannot reach, it will be swiftly shattered by microwave-induced freak-wave scission. Once the vibrational analysis of a given virus has been completed, DREADCO's programmable multifrequency microwave generator will be able to blast it out of the body on demand. Influenza, glandular fever, hepatitis, even the common cold, will surely succumb to this potent therapy. Even if the virus mutates in self-defence, a re-analysis of its new form will put it firmly back in DREADCO's sights. David Jones

Announcing a unique RIA technology – it's in closer proximity than you think

- No liquid scintillation cocktails required
- Time saving
- Cost saving
- Increased safety
- High performance

Amersham introduces Scintillation Proximity Assays

- No separation of bound from free required
- Simple to use; convenient protocol
- Readily automatable

Full details on the theoretical and technical aspects of scintillation proximity assays are given in our technical booklet 'Scintillation Proximity Assays — principles and practice', available on request.

Products available

- **Generic reagents** — for the development of in-house assays

Bamboo flowering and pandas

SIR—The flowering and subsequent natural dieback of arrow bamboo in Wolong and other areas in China in 1983 did not cause the mass starvation of pandas that was feared because they foraged on alternative bamboo species or unflowered arrow bamboo patches[1-3]. Now that the perceived crisis has passed, efforts to conserve the panda can focus on the urgent problems of poaching, habitat preservation, release of captive animals and development of a captive-breeding programme[1,4,5]. But an unusual opportunity to restore degraded panda habitat should receive equal attention.

Even though bamboo density is greater in those areas of Wolong that were clear-felled in the 1960s and 1970s than in the still-forested areas, pandas prefer forest habitat. Few trees, especially conifers, became re-established in the clearcuts because of the dense vegetatively propogated bamboo, but conifers dominate the subalpine forest in Wolong and old hollow conifers serve as maternity dens for pandas[5-7].

We therefore urge the immediate planting of native conifers in the areas cleared by the 1983 dieback before the regrowing arrow bamboo has reached a size that would inhibit conifer establishment—this requires 10–15 years. Rapid development of conifer forest from planted seedlings may also help reduce the high bamboo seedling mortality observed in clearcuts[8]. Cost-effective opportunities to restore degraded panda habitat to conifer forest are infrequent because arrow bamboo will not flower again for 45–50 years[5,9].

Basis of hepatitis delta virus disease?

SIR—Symons[1] has recently discussed a reported[2] sequence complementarity between the six viroid 'species' that cause disease in tomato plants and tomato 7S RNA, a small cytoplasmic RNA present in various organisms as a component of the signal recognition particle, a structure involved in the translocation of secretory and membrane-associated proteins. It has been suggested that formation of hybrids between viroids and 7S RNA may be a factor in disease[1,2]. We wish to extend that suggestion to the hepatitis delta virus (HDV), a human pathogen that causes severe liver disease (delta hepatitis) throughout the world[3].

Similarities between viroids and HDV have been demonstrated previously. Like viroids, HDV has a circular, single-stranded RNA genome that possesses a high degree of self-complementarity[4]. HDV RNA is believed to replicate via a rolling cycle mechanism through an anti-genomic RNA replication intermediate[4]. Also, limited sequence similarity has been reported between viroids and HDV RNA[4].

We have found that an extensive complementarity exists between two regions of human 7SL RNA[5] (the counterpart of tomato 7S RNA) and anti-genomic HDV RNA[4] (see figure). The first region involves nucleotides 10–55 of 7S RNA and 683–724 of the HDV replicative intermediate. In a 48-nucleotide domain, 35 (73%) bases are complementary (including two G:U base-pairs); three stretches of 6–8 nucleotides are perfectly base-paired. The second region of complementarity is found between bases 188–230 of 7SL RNA and 858–899 of anti-genomic HDV RNA. In a 44-nucleotide domain, 34 (77%) bases are complementary (including three G:U base-pairs). Two long stretches, 12 and 9 bases in length, of perfectly paired nucleotides are found at the ends of this domain. The sequences that separate these two regions, although approximately of the same length (132 and 133 nucleotides), do not show any significant complementarity. Of the 69 nucleotides of the anti-genomic HDV RNA complementary to 7SL RNA, 67 are invariant among the three known HDV sequences[4,6,7], whereas other regions of HDV show a rather high heterogeneity. Thus, the region of HDV anti-genome exhibiting complementarity with 7SL RNA is highly conserved among the known virus isolates.

```

Proposed base-pairing between human 7SL RNA and anti-genomic HDV RNA. Colons indicate G:U base-pairs. Lowercase letters denote the two nucleotides that are identical in two reported HDV RNA sequences[4,6] but differ in a third[7].

The suggested base-pairing between human 7SL RNA and anti-genomic HDV RNA is even more extensive (and possibly more stable) than that between tomato 7S RNA and the six viroids. Interestingly, the region in tomato 7S RNA (bases 26–67) thought to be capable of annealing to viroid RNA corresponds to one of the regions of the human 7SL RNA complementary to the anti-genomic HDV RNA. However, due to sequence differences between tomato 7S RNA and its human counterpart[2], there is no significant similarity between anti-genomic HDV RNA and viroid RNA in this region.

Thus, just as viroids may cause disease by base-pairing to a host structural RNA, so may a replicative intermediate of HDV. As HDV is known to replicate inside the nuclei of infected hepatocytes[8], its anti-genomic form may anneal to the 7SL RNA shortly after the host RNA is transcribed and before it becomes incorporated in the signal recognition particle. This hypothesis is consistent with the notion that HDV is directly cytopathic[3] and can be tested experimentally. If true, it might lead to new therapeutic strategies for the control of delta hepatitis.

Aurorae aplenty

SIR—Schröder's suggestion[1], that the Maunder minimum[2] of solar activity does not show up in European auroral records, is corroborated by historical evidence from the Soviet Union. Although the great aurora of 16 March 1716 (Julian) seemed to awaken the scientific society of the time, initiating studies of the ionosphere, there were nevertheless useful observations made in the middle latitudes

of Eurasia for 70 years before this.

My collection includes observations from Russian, Ukrainian, Polish and Armenian sources, as well as some German ones and an English text recounting that Patrick Gordon, a general and rear-admiral in the service of Peter I, saw the great aurora in Kiev on 1 June 1685. Only a fraction of these sources are known to historians of geophysics, much of the information having been derived by Yu. A. Mytsyk, of Dnepropetrovsk University, and myself from antique publications and manuscripts.

Scientific observations in Russia date back to 1725, but the tradition of chronicle-writing seems to have failed in the mid seventeenth century. But in that period several new sources arose: Ukrainian chronicles, which appeared at a time of national revival; Siberian annals owing their origin to a rapid Czarist expansion to the East and the foundation of autonomous Siberian cultural centres such as Tobolsk and Tomsk; and new Russian translations of West European records, the originals of which may be lost.

This last category includes the early periodicals (*Zeitungen, Anzeigen, Berichten* and so on). Muscovite commercial and diplomatic agents gathered information from these sources and sent it to Russia. A single hand-written copy of *Vesti-Kuranty*, compiled at the Czar's court, has been preserved in Russian archives, recording German, Danish, Swiss and Hungarian aurorae otherwise unknown to West European scientists.

Russian sources record 57 (perhaps 61) auroral phenomena from 1645 to 1715. Schröder[1] thinks there were 110 (perhaps 130) cases in Central Europe, and the late Professor M. Keimatsu's collections contain 26 observations from the Far East. All in all there are 193 (perhaps 217) cases, eight of which coincide (for example, one aurora was seen simultaneously in Chernigov and Kyoto).

During the 70 years, about 185 (209?) aurorae were noted, an average rate of 2.8 (3.0?) a year. This is similar to the typical rate of aurorae now seen in Moscow or Berlin. We can conclude that the term Maunder minimum should be placed between inverted commas when it refers to auroral activity.

Lateral preference and longevity

SIR—Longevities of right-handed and left-handed baseball players have been compared[1,2] unadjusted for birth date. To obtain a potentially more accurate paired comparison, I treat each birth year as a cohort. I have included players born up to 1922 classified by throwing hand (as in ref. 2) and use 'R–L' to designate the mean longevity of right-handers minus that of left-handers within each birth year.

R–L has a higher variance towards the earliest and latest birth years because these contain the smallest proportion of the 4,479 deceased players[3] studied. To obtain a homogeneous variance as assumed in regression, successive R–L estimates were combined into groups, beginning at the first year, until each group included at least 25 left-handers. (Left-handers comprise 18 per cent of the player population and therefore contribute most of the variance.) The resultant 23 groups each included 25 to 50 left-handers. The mean birth date and R–L for each group were the averages weighted by the number of left-handers in each birth year.

Using this grouped data, the mean R–L is zero but there is a significant ($P<0.01$) negative linear regression of R–L on birth date, B: R–L = 3.36 − 1.38 B where B is (birth year − 1868.54)/10.

Obviously, R–L cannot decline indefinitely. It is plausible that stress factors[1] or discrimination against sinistrals decreased left-handers' longevity historically. Our lifespan has presumably been genetically selected for good reproductive fitness. There would, therefore, have been selective pressure to evolve a linkage between left-handedness and a factor for increased longevity, partially offsetting the lower longevity otherwise associated with left-handedness.

If such linkage exists, removal of handedness-related stresses in modern times would have shifted R–L from positive to negative, just as the preceding regression equation implies. According to this hypothesis, R–L would approach a negative value asymptotically as handedness-related stresses decrease at various rates. Therefore, an asymptotic regression[4] was fitted:

$$\text{R–L} = \underset{(\text{s.e.}=1.22)\ (P<0.01)}{-3.73} + \underset{(\text{s.e.}=2.60)\ (P<0.01)}{8.69} \times 0.67^{B}$$

Right-handers born before 1890 had an advantage. Thereafter, left-handers had an advantage asymptotically approaching 3.73 years. Without extrapolating, left-handers' advantage was estimated at 2.1 years for those born in 1910, with 95 per cent confidence limits of 0.4 to 3.8 years. Presumably this relationship holds generally, rather than resulting from the players-selection process or a fluke. The advantage of being left-handed parallels the advantage of being female in affluent societies, and I suggest these have a similar evolutionary explanation. According to my hypothesis, it is predicted that left-handers will be found to have greater longevity than right-handers among Americans on average; conversely, sinistrals' longevity will be lesser in countries with low and approximately equal male and female longevities still prevailing.

Dating of the Ugarit eclipse

SIR—De Jong and van Soldt[1] have reanalysed clay tablet KTU 1.78 found in Ugarit in 1948 and suggested that the text on the tablet pertains to a solar eclipse which occurred in the second millennium BC. As Walker[2] has already pointed out, their dating is speculative. In addition to Walker's assyriological reservations, an objection on astronomical grounds is also necessary.

The text refers to a phenomenon which may very well be interpreted as a solar eclipse: (Obverse) "On the ... day of the new moon in (the month) hiyaru the Sun went down, its gate-keeper was Rśp"; (Reverse) "Two livers were examined: danger". Tacitly de Jong and van Soldt assume that the eclipse was total, though this is by no means clear from the text. The Ugaritic terminology is not sufficiently well known to identify the term "the Sun went down" as a total eclipse; it might have been a partial eclipse. The 'gate-keeper' Mars in the text does not help to clarify the situation either, because its occurrence might just be the result of an astrological calculation or of a connection of the planet with a certain month or year. It is interesting to note in this respect that the only preserved material related to tablet KTU 1.78 consists of two fragments of almanacs and one astrological text.

The last possible reason for considering the eclipse text to refer to a total eclipse is its mere survival. The assumption is often made that when only a few records of solar

eclipses survive, they refer of necessity to total elipses. This is not necessarily true, as was already pointed out by Newton[3]. Furthermore, I recently presented a solar eclipse record which can serve as a counter-example, namely the only account of a solar eclipse from the *Chronographia*, a fourteenth century historical work. It is the only record of a solar eclipse in that work, but nevertheless it is with certainty a record of a partial eclipse[4,5]. It is therefore possible that the Ugarit record also refers to a partial eclipse. If so, dating the record is not feasible in view of the larger number of possibilities. In conclusion, the record of a solar eclipse of the second millennium is still not dated with certainty and conclusions drawn from the dating should be met with some reservation.

Epithelial homing of γδ T cells?

SIR — Only one or two per cent of T lymphocytes in systemic lymphoid organs or blood, of mice and men, express the γδ T-cell receptor (TCR) for antigen; this minor fraction mainly consists of cells that carry the CD3 antigen but not the CD4 or CD8 antigens and so are termed $CD3^+CD4^-CD8^-$ or 'double-negative'[1]. It was therefore remarkable when intra-epithelial lymphocytes (IEL) isolated from the murine gut were reported to be exclusively $CD3^+CD4^-CD8^+$ and, by immunoprecipitation, seemed to bear mainly γδTCR (refs 2 and 3). Similar results were obtained by immunohistochemistry for avian and apparently also for human IEL[4]. A tissue-specific distribution of TCR subtypes has now been proposed[5], but has received a sceptical response[6,7].

We tested this theory with BMA031, an αβ framework antibody[8], and 11F2 that reacts with all types of γδTCR (ref. 9). In immunocytochemical tests on a $CD3^+$ double negative γδ T-cell line, these monoclonal antibodies behaved correctly; but they performed unsatisfactorily on cryostat sections. Labelling of viable T cells was therefore performed by permeation of fresh jejunal biopsy specimens with these two antibodies and with antibodies to CD8 and CD4 (Dakopatts)[10]. Membrane expression of αβTCR was seen abundantly in the lamina propria and also on a variable number of IEL (Fig. 1*a*). The proportions of $CD8^+$ and αβTCR IEL obtained in the seven normal cases were well correlated (Pearson's $r=0.865$). To compensate for variable antibody diffusion, the results for αβTCR, γδTCR, and $CD4^+$ IEL were adjusted by a factor derived from the corresponding $CD8^+$ to $CD3^+$ ratio, taking 90% as the average 'true' value[11]. The median αβTCR fraction of $CD3^+$ IEL was thus estimated to be 92% (64–100%, $n=3$) with labelling at 37 °C for two hours and 70% (41–100%, $n=4$) at 4 °C for two to eight hours. Conversely, the proportion of γδTCR was usually below 8% and that of $CD4^+$ IEL below 13% (median, 9%).

The figures obtained for three coeliac disease specimens indicated that there might be a relative increase of γδTCR (1–16%) compared with the αβTCR (median, 48%) and $CD4^+$ (median, 9%) IEL. Such a disease-associated change (Fig. 1*b*) could reflect the increased intra-epithelial $CD3^+$ double-negative subset recently identified in this disease[12].

In conclusion, we have shown that most human intestinal IEL express the αβTCR. Moreover, almost half of the $CD3^+$ IEL were found to be positive for the UCHL1/CD45 molecule[10]; this implies that they are probably $CD3^+CD8^+$αβ memory T cells.

We have recently used another set of monoclonal antibodies, namely βF1 and TCRδ1 from T Cell Sciences (Cambridge, Mass.), and have confirmed by immunohistochemistry on cryostat sections that αβTCR cells are strikingly predominant among human IEL, and that the γδ TCR fraction is indeed increased (from a normal median of 2% to 22% in treated or untreated coeliac disease). The CD8 expression of this fraction is decreased (from 25% to 10%) and CD4 expression is not seen. Also notable is the finding that the intestinal γδ TCR^+ cells are mainly located in the epithelium, both normally and in coeliac disease (T.S. Halstensen *et al.*, *Scand. J. Immun.*; in the press).

Borst), respectively. Mucosal surface at the top. Epithelial basement membrane indicated by broken line (×400).

SIR—Regarding the controversy that has already surfaced in *Scientific Correspondence* on the frequency of γδ T cells in human intestinal epithelium[7,13] my collaborators, Chen-lo Chen and Max Cooper, and I have investigated the tissue localization of cells expressing the δ-chain with the monoclonal antibody to TCRδ1 of Michael Brenner. This appears to recognize a constant region of the TCRδ chain[14], unlike δTCS1 used by Spencer and Isaacson[7], which recognizes a subset of the γδ T cells[14]. We found that 80% of γδ T cells in the intestinal mucosa are localized in the epithelium while the remaining 20% are in the lamina propria[15]. Nevertheless, these cells comprise a minor subset (about 7%) of the intraepithelial $CD3^+$ cells. In the chicken[4], we observed the same γδ T cells homing into the intestinal epithelium but it is noteworthy that only half of the epithelial $CD3^+$ cells express the γδTCR. A majority of these are $CD8^+$, and none express CD4.

The preferential tissue localization

pattern of γδ T cells must be an important clue to the function of this T cell sublineage[16]. However, the distinctive tissue localization pattern is not strictly an epithelial tropism. The preferential homing of γδ T cells to the epidermis that is seen in the mouse, is not observed in either chickens or humans. Furthermore, we have observed a selective homing pattern in the spleen that is phylogenetically conserved. In both chickens and humans[4,15] the γδ T cells preferentially localize in the splenic red pulp rather than the periarteriolar lymphoid sheath, which contains the majority of the splenic αβ T cells. Since the relationship of the splenic red pulp to a system of epithelial defence is not obvious, these observations suggest a more general function for γδ T cells rather than a defence role restricted to the epithelial boundaries of the body.

R. PAT BUCY

Department of Pathology, University of Alabama at Birmingham, Birmingham, Alabama 35294, USA

SIR—We would like to contribute to the discussion concerning the preferential localization of γδ T cells in human epithelia. In the murine system it has been observed that γδ T cells are present in epidermis and intestinal epithelium in much higher frequency than αβ T cells. Janeway in particular, has elaborated on this finding and put forward the general suggestion that γδ T cells could play a particular role in immunosurveillance at these sites[5,16].

We have looked into the distribution of γδ T cells versus αβ T cells in a variety of normal human tissues of lymphoid and non-lymphoid nature. Serial sections of freshly frozen tissue were acetone fixed, incubated with anti-CD3, anti-TCR γδ-1 (ref. 9) and βF1 (anti-TCR αβ) (ref. 17) monoclonal antibodies and stained according to a highly sensitive immuno-alkaline phosphatase method. We studied bone marrow; fetal and neonatal liver; fetal and neonatal thymus; fetal, neonatal and adult lymph nodes; adult spleen and tonsil; neonatal and adult skin[18,21], oesophagus, stomach, small and large intestine, lung and trachea, testis, epididymis, uterus, vagina, kidney and brain.

At all sites within these organs αβ T cells constituted over ninety per cent of $CD3^+$ cells. γδ T cells comprised less than ten per cent of $CD3^+$ cells. Therefore, we conclude that there is no evidence for preferential homing or localization of γδ T cells in human epithelia. However, in none of the organs were γδ T cells observed in lymph follicles (of lymph nodes, tonsil, spleen, Peyer's patches or lung). Also, the percentage of γδ T cells in epidermis seemed on average higher than in papillary dermis. Therefore, there may still be a difference in migration of γδ versus αβ T cells, but this does not result in their preferential localization in epithelia. With respect to morphology of γδ T cells and αβ T cells, we find that generally they cannot be distinguished, but occasional $CD3^+$ cells with dendritic appearance always proved to express γδ TCR.

In view of these findings, great caution should be taken in ascribing a special function to γδ T cells in immunosurveillance of human epithelia. Future intensive and thorough investigation should reveal what contribution these cells make to the immune system.

JANEWAY REPLIES—The above letters raise two questions. First, do T cells bearing γδTCR have a special tropism for epithelia, and second, is this tropism seen in man? In addition, the letters appear to contain a misapprehension of the content of two articles[5,16] that I have written on this topic. These articles propose that one role γδ T cells might have is defence of epithelia from intracellular infection and/or transformation, and that such cells might recognize not foreign antigen but an alteration in the host cell surface induced by infection. Both articles clearly state that such T cells are also found in other sites where they must mediate other functions. Thus, I do not take issue with the conclusion of the above letters that epithelial defence is not the only role such cells play. There are, however, strong data arguing that some T cells of this class exhibit this specialization.

Since this proposal was made, we and others have shown that T cells bearing γδTCR are in fact the dominant population in murine intestine[2,3]. More importantly, we have shown that such cells express receptors encoded by the $V_{\gamma 7}$ gene V_γ not expressed by γδ T cells in any other tissue[3,19]. S. Tonegawa *et al.* have shown that the $V_{\gamma 6}$ gene, again not expressed by γδ T cells in other tissues, is used in reproductive epithelium (personal communication), while Allison *et al.*[20] have shown that the $V_{\gamma 5}$ gene is expressed only by γδ T cells in epidermis. Thus, in addition to tropism to epithelia, there is a marked restriction in the specificity of γδ T cells found in these tissues. This does not prove that T cells with γδTCR are specialized for epithelial defence, but it certainly is most readily explained in the context of our earlier hypothesis. Recently, experiments with mice transgenic for γδTCR show that epithelial homing is a property of the γδ T cell lineage and not of particular γδTCR specificities. Specificity appears to reflect ligand recognition in the epithelia (M. Bonneville *et al.* personal communication). This further supports a functional role for those γδ T cells in epithelia. Perhaps studies of *V*-gene usage in γδTCR in humans would show similarly specific localization.

The human studies cited show predominance of T cells with αβTCR in intestinal epithelium. From examining photographs of such sections, however, Bucy notes (above) that the T cells with γδTCR show tropism for the epithelial layer whereas T cells with αβTCR do not. Thus, the human data on tropism of γδTCR-bearing cells to epithelia do not conflict with those in the mouse. Rather, this tropism is masked by the presence of large numbers of T cells with αβTCR found in humans but not mice or chickens, where similar studies show 20–40% of T cells with αβTCR. Thus, the obvious species difference may reflect differences in the behaviour of αβ cells and/or differences in the actual γδ receptors, rather than differences in function or tropism of T cells with γδTCR. Until these issues are resolved, it is as unwise to state that T cells with γδTCR are *not* specialized for epithelial immunity as it is to state that this is their only function, or that only γδ T cells can perform such functions, neither of which I have claimed (although such claims have been attributed to me).

ALKALINE PHOSPHATASE

6000 U/mg

The highest specific activity available

Over the past seventeen years, Biozyme has developed the isolation of highly purified enzymes for diagnostic, pharmaceutical and immunochemical application.

The latest development is Alkaline Phosphatase (from Calf Intestine), Code ALPI-11G assaying at 6000 U/mg protein (Biuret) or greater (Diethanolamine buffer, 37°C). Offered as a 50% glycerol solution, this presentation has a stability of at least 18 months at 0-5°C.

We list below the range of Alkaline Phosphatase prepared in our laboratories with relative activities in three assay systems, as follows:-

Product Code	Glycine Buffer pH9.6 25°C Biozyme Assay U/mg	Glycine Buffer pH10.4 37°C U/mg	Diethanolamine Buffer pH9.8 37°C U/mg
ALPI-8G	>1100	>1400	>3000
ALPI-9G	>1300	>1700	>4300
ALPI-10G	>1500	>2100	>5000
ALPI-11G	>1700	>2300	>6000

Quantikine™

For the Precise Quantitation of Cytokines.

ELISA Kits for TNF-α, IL-1β*, IL-4*, IL-6

R&D Systems' Quantikine series of cytokine assays provides a sensitive, extremely accurate determination of the amount of a given human cytokine in cell culture media, sera and other fluids.

Each Quantikine kit features:

- A 96 well, 12 strip plate, *pre-coated* with a monoclonal capture antibody.
- A directly conjugated detection antibody.
- Complete reagents for testing of serum and tissue culture samples.

FOR RESEARCH USE ONLY
NOT FOR DIAGNOSTIC OR THERAPEUTIC PROCEDURES
*Available October 30, 1989

Sensitive: linear in the range of 20-2000 pg/ml; minimal detectable amount <10 pg.

Precise: well-to-well CV <8%

Specific: results not influenced by the presence of other cytokines.

Accurate: eliminates the inherent imprecision of bioassays.

Rapid: simple 7 step procedure, data in <4½ hours from receipt of kit.

Add sample...Incubate (2 hours)... Wash...Add Detection Antibody... Incubate (2 hours)...Wash... Develop...Read Results.

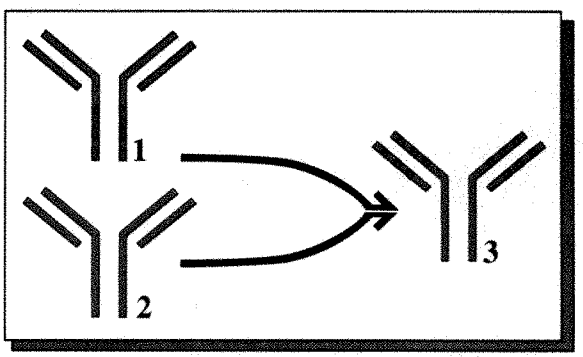
SCOTGEN

RESHAPING ANTIBODIES



SCOTGEN is offering a service to commercial clients to produce human monoclonal antibodies from their rodent counterparts using the RESHAPING technology invented by Dr Greg Winter.*

SCOTGEN is an established contract protein engineering and genetic technology company, specialising in antibody engineering, and is also developing its own products in specific niche markets. We are expanding our antibody engineering team at present to handle increased work in this area.

A RESHAPED antibody is essentially all human, even though it has the same antigen recognition site as its rodent counterpart. It is an advance over chimaeric antibodies in having less anti-globulin response in patients and, therefore, improved in vivo potential.

During the **RESHAPING** process other features can be built in or altered - isotype, ± Fc receptors, expression of Fab only, or the binding site to change the affinity or alter the specificity.

SCOTGEN has close scientific links with the major UK academic researchers, who are the inventors and world leaders in these fields.

1. MOUSE ANTIBODY
with desired binding characteristics e.g. tumour antigen recognition.

2. HUMAN ANTIBODY

3. RESHAPED ANTIBODY
has the same antigen recognition sites as the mouse antibody but all the rest of the molecule is human.

AIMS AND SCOPE

Developmental Immunology aims to be a monthly journal devoted to reports of significant research in the field of phylogeny and ontogeny of the immune and hematopoietic systems. Both cellular and molecular aspects of developmental immunology will be considered. *Developmental Immunology* will provide a rapid and vigorous review process with fast publication. In addition to original papers, mini-reviews and short communications are also invited. The editors and publisher will maintain high standards in the quality of accepted papers and in the presentation of the journal.

Virology

Directory and Dictionary of Animal, Bacterial and Plant Viruses

R. Hull, F. Brown and C. Payne, Eds.

This is an indispensable reference work for all scientists working with viruses as biochemical tools or as the agents of infectious disease. Many general, as well as technical terms are defined including aspects of molecular biology and genetic manipulation. Compiled by internationally renown authors, this comprehensive work also lists cell lines and provides equations, formulae and definitions.

international immunology

MONTHLY FROM 1990!

Editor-in-Chief: **Tomio Tada**, Department of Immunology, Faculty of Medicine, University of Tokyo, Tokyo, Japan 113

Editorial Board: **F. W. Alt, B. R. Bloom, M. D. Cooper, Leonard A. Herzenberg, Leonore A. Herzenberg, T. Kishimoto, N. Le Douarin, T. W. Mak, F. Melchers, N. A. Mitchison, G. J. V. Nossal, K. Rajewsky, R. H. Schwartz, S. Tonegawa**

- ▶ contains original research papers — presenting new results of interest to a broad spectrum of immunologists and providing enough information for observations to be evaluated and repeated
- ▶ is thoroughly international in concept and execution
- ▶ publishes papers on specialized techniques and advances
- ▶ includes critical essays dealing with particular areas in a thoughtful manner
- ▶ publishes short communications rapidly
- ▶ gives contributors the benefit of the highest level of presentation, with superb quality half-tones
- ▶ accepts papers on disk
- ▶ is received by over 3500 immunologists as part of their national society membership

Christopher C. Booth

Health for Sale: Quackery in England 1660–1850. By Roy Porter. *Manchester University Press: 1989. Pp.280. £19.95, $35.*

HOGARTH'S famous engraving "The Company of Undertakers" portrays a group of pompously bewigged physicians together with a trio of famous quacks. There was, for the eighteenth-century patient, not much to choose between them. To little avail, the doctors bled, purged, blistered and clystered, cloaking their ignorance behind the Latin that was supposed to be the mark of their erudition. They did not always get away with it. William Cobbett described the Philadelphia physician, Benjamin Rush, known in his day as the American Hippocrates, as "a poisonous transatlantic quack", a "Samson of medicine who slaughtered thousands of citizens". But for the most part the conventional profession was regarded as the fount of medical knowledge, and all others pretending to benefit the public with their nostrums were considered to be quacks, charlatans or mountebanks.

Mary Evans

Good vibrations — Mesmer's tub, an etching from 1790. Rods connected to a 'magic box' allegedly provided healing through transfer of vibrational energy

There was, however, not a great deal of difference between the recipes of quacks and those of the established profession. Until as late as 1786, the London physician could officially prescribe the Venice treacle or Mithradatium, a remedy that contained as many as 65 ingredients including the dried flesh of vipers Furthermore, no physician was reluctant to usurp the therapies used by herb-women and others, who were not considered by the suffering humanity of two centuries ago to be the artful, tricking practitioners of physic that Samuel Johnson regarded with such malevolence. The Earl of Chesterfield was as likely to sample the nostrum of a quack as to consult the owner of a gold-headed cane. We also do well to remember that digitalis was discovered in a family recipe for the dropsy kept by an old herb-woman in Shropshire, and that the development of both ophthalmic surgery and of orthopaedics owes much to the irregular practitioner.

In *Health for Sale*, Roy Porter sets out to put quackery in England in its historical context between 1660 and 1850. He begins with an interpretation of quackery, emphasizing how medical history must be seen as part of economic and social history as a whole, how sufferers interrelated with the ambitions of practitioners, both regular and irregular, and how the practices of quacks cannot be divorced from a consideration of the orthodox. He sees the quack, no less than the regular doctor, as an entrepreneur in a consumer society, serving a public whose desire for medicines was only matched by the enthusiasm with which practitioners of all types dispensed them. He tells us of the career of quackery, how it ranged from the anonymous itinerant to the most famous in the metropolis — Mrs Mapp, for example, the bone-setter of Epsom, who was portrayed in Hogarth's print and who rode to town in style in her coach and four.

Perhaps the most remarkable of them all was Mrs Joanna Stephens, whose medicine for the treatment of the stone had reputedly relieved Sir Robert Walpole. Parliament rewarded her with the astounding sum of £5,000 for revealing her secret remedy, which was found to consist of "eggshells and snail shells, both calcined, wild carrot seeds, burdock seeds, ashen keys, hips and haws, all burnt to blackness and mixed with alicant soap and honey". It seems to have been remarkably ineffective, since there were still a number of stones in Sir Robert's bladder at his death. Yet Mrs Stephen's lithotryptic had its influence on the history of science, for it led the remarkable Reverend Stephen Hales to suggest that its active ingredient was lime, it was lime water that led Joseph Black to the experiments in which he discovered carbon dioxide.

With the breadth of scholarship that is his characteristic, Porter deals with the culture of quackery, with advertising, and with images of health, disease and cure. Quacks were very much involved in sexual matters, particularly in the treatment of venereal disease. There were, furthermore, quacks who were not only peddling pills. The more famous, such as Cagliostro and John (Chevalier) Taylor, were not averse to parading their own prowess as seducers in purveying their wares. James Graham's famous Celestial Bed in his Temple of Hymen at the Adelphi, where childless couples could seek success surrounded by currents of electricity, was the *chef d'oeuvre* of a "wizard showman flourishing in the lubricious twilight-world of sex aids".

Quacks frequently became embroiled in quarrels, but their differences with the doctors almost always worked to their own advantage. Of all those of the regular profession who sought to dispose of the quacks, however, there was none so vitriolic nor so successful as Thomas Wakley, who in his newly founded journal, *The Lancet*, attacked them with particular venom and hatred. Quackery was now on the retreat, for the nineteenth century was to be a period when, with the emergence of regular, professional medicine, it gave way to a popular fringe, often motivated less by the pursuit of filthy lucre than by the credo of the crusader.

Porter gives a highly readable account of his subject, and he is at his surest when dealing with what he describes throughout as "the long 18th century". All the well-known and many of the lesser lights are here. His view of medical history embraces not only the lives of the practitioners he so sympathetically describes, but also the views of their long-suffering patients. The work is admirably referenced and there is an excellent bibliography.

There is, however, a tendency to unnecessary repetition which could have been avoided by more careful editing. There may also be those who would have preferred a more chronological account, with perhaps some analysis of the nature of illness in England at the beginning and end of the period under review. After all, in 1660, the nation still had to experience the horrors of the last great plague in England, an epidemic which played an important role in the relationship between regular and irregular practitioners. By 1850 the pattern of infectious disease had changed. With the increased rapidity of travel, cholera had reached these shores Diseases, no less than those who seek to treat them, have a history of their own. □

Inside story

Peter J. Smith

Theory of the Earth. By Don L. Anderson *Blackwell Scientific· 1989. Pp.366. £49.50, $65*

GEOPHYSICS and geochemistry each has its own special techniques and a huge body of accumulated knowledge. By definition they are distinct disciplines and have, by tradition if not necessity, been studied by distinct groups of people who have communicated with each other all too infrequently. Indeed, such are the pressures to specialize that disciplinary segmentation has gone even further, with Earth scientists now describing themselves solely as seismologists, geomagnetists, geodesists, petrologists, mineralogists, meteorite specialists, or any one of a number of other '-ists'.

Unfortunately, the Earth's interior not only fails to acknowledge such divisions, it insists on dragging in a whole range of topics not recognizably geoscientific at all — cosmochemistry, solid-state physics, thermodynamics, crystallography, astronomy, among others. The consequences are a fair degree of chaos and not a little wasted effort. For as Anderson himself points out, even when people in different disciplines look over each other's shoulders, which is rare enough, they don't always understand the limitations of what they see, with the result that "one discipline's unproven assumptions or dogmas are treated as firm boundary conditions for a theoretician in a slightly overlapping area" (p xi).

There may be no solution to all this. No one is superhuman, either in the sense of having the ability to comprehend all the relevant subdisciplines or in the sense of having the time and dedication to assimilate completely the bodies of knowledge they represent. On the other hand, much to the envy of the rest of us, there are a few people within the Earth-science community who are, well, fairly superhuman. Don Anderson is one of them — as close to being the compleat geophysicist/geochemist as anyone is ever likely to be.

Theory of the Earth, then, is an extensive summary of practically everything 'known' about the physics, chemistry and physicochemical evolution of the Earth's interior — the formation of the planet as part of the Solar System; the Earth's bulk composition and the origin of its layering; the physical and chemical characteristics of the crust, mantle and core; the thermodynamics, equations of state, elasticity and solid-state physics of the Earth's interior; the composition and evolution of the mantle and the nature of the geochemical reservoirs therein; the Earth's shape and heat flow; convection in, and the heterogeneity of, the mantle; mantle phase changes; and the Earth's anelasticity and anisotropy.

These are, so to speak, the broad subheadings, although in themselves they give only a poor idea of what Anderson is about, which is integration. The point here is that the data from any one subdiscipline are often consistent with a whole range of hypotheses but that the possibilities can be narrowed considerably by bringing to bear data from other fields. What we truly know of the Earth's interior could probably be written on the back of an envelope (hence the inverted commas around 'known' in the previous paragraph), but we can reduce the options for uncertainty. This is Anderson's great achievement — to show how evidence from diverse sources can be used to constrain our ignorance, to rule out the impossibilities and thus reduce the range of possibilities and perhaps even point to probabilities.

This is not really a book for beginners. A great deal of prior knowledge is required (from definitions, through the nature of particular minerals and the use of partial differential equations, to the basic philosophy of Earth-science investigation). There is little about experimental techniques, and in a few places there might just be alternative views. Within these constraints, however, Anderson has produced a remarkable synthesis of our present understanding of the Earth's interior. □

Peter J. Smith is in the Department of Earth Sciences, Open University, Walton Hall, Milton Keynes MK7 6AA, UK.

In the family

P.V.E. McClintock

Near Zero: New Frontiers of Physics. Edited by J.D. Fairbank, B.S. Deaver, Jr, C.W.F. Everitt and P.F. Michelson. *W.H Freeman: 1989. Pp. 959. $59.95, £47 95*

FEW twentieth-century physicists contribute usefully to more than one fairly specialized area of the subject, and those that do are usually theorists. Landau and Feynman are particularly striking examples but others, too, have found that their theoretical tools developed to deal with one particular problem (say superfluid helium) can also be applied fruitfully in other apparently unrelated areas of the discipline (the structure of neutron stars, for example). The situation for experimental physicists is quite different, in that their skills tend to be less portable. Most of them spend their entire careers working within, or close to, the same narrow specialism that they entered in their twenties. There are some notable exceptions, of course, and none more notable than W.M. (Bill) Fairbank of Stanford University in whose honour *Near Zero* has been compiled.

To many scientists, Fairbank is just "the man with the niobium balls", who reported the seemingly outrageous experimental observations of fractional charge (quarks?) on tiny niobium spheres levitated in a capacitor above superconducting coils. Low-temperature physicists, and many cosmologists and particle physicists, will of course be well aware that his contributions to science have been vastly greater than this one famous (or infamous, depending on your standpoint) experiment. But even they are likely to be surprised by the astonishing scope and breadth of the work described in this substantial tome.

Compiled by more than 80 contributors, mostly his ex-students and colleagues, the book amounts to a form of scientific biography. It charts in anecdotal detail Fairbank's early life and education; his marriage; his conversion from chemist to physicist; his entry to the world of low-temperature research at Yale; the epoch-making experiments on liquid helium at Duke; and the subsequent extraordinary efflorescence of imagination, creativity and innovation at Stanford, possibly as a reaction to remarks by a blunt friend: "I hear you've got a chance to go to Stanford. You are 42 years old, and I know what happens to such people; I've made a study of it. You get an ultimate position that's very nice at a very good university and you don't do anything more for the rest of your life".

Whether these forthright comments affected the outcome is unclear, but it is certain that no prediction could have been wider of the mark.

Much of Fairbank's work has been guided by the theme of "near zero", which can be construed in various ways. Originally, he used the phrase to refer to experiments near the absolute zero of temperature. Later, it took on a wider meaning as it became clear that frontiers of physics could also be reached by reducing other variables almost to zero, and his experiments have, for example, treated magnetic field, electric field and gravity in just this way. The book has its genesis in a conference of the same name honouring Fairbank's 65th birthday in 1982, for which it effectively constitutes the (somewhat belated) proceedings.

Despite its diverse range of seemingly unrelated topics, and the huge number of contributors, the work as a whole is remarkably unified and coherent. Partly, no doubt, this is the result of careful editing, but it also arises from the fact that the entire corpus is based on the scientific life

and interests of a single individual. The opening sections include reminiscences by the late Walter Gordy on his work with Fairbank both at MIT in wartime and later at Duke. There is also a lengthy, affectionate, wide-ranging and thought-provoking article by C.W F Everitt on the nature of the creative process, analysing the origins of Fairbank's imaginative contributions to experimental physics in the context of illustrious predecessors such as Boys, Eotvos and Rutherford.

The bulk of the book, however, is taken up with individual papers on key scientific topics with which Fairbank has been concerned. They are mostly written with an historical/anecdotal flavour by his collaborators of the time in question, and very much from individual points of view, but also bring the subject more up to date and set it in the context of subsequent work. The papers are grouped in chapters covering liquid and solid helium, superconductivity and its applications, fundamental physics (including fractional charge), gravitation and astrophysics, and the surface-shielding effect. Finally, there is a characteristically thoughtful and intriguing chapter by Fairbank himself, presenting his ideas on the future frontiers of physics.

This is very much a family book for a family occasion — not only are Fairbank's close colleagues and collaborators among the contributors, but so too are his brother, the distinguished low-temperature physicist Henry Fairbank, and his laser-physicist son William M. Fairbank Jr, and his wife Jane Davenport Fairbank is one of the co-editors But is there anything in the book of interest to people outside this immediate family?

The answer must emphatically be yes. All low-temperature physicists will have come across Bill Fairbank or his work in the context of his many contributions to the understanding of liquid helium and superconductivity. Most physicists, and many non-physicists, have heard of the (still highly controversial) fractional charge experiments, of the Stanford Relativity Gyroscope experiment, of the positron free-fall experiments and of the experiments on gravitational waves. All of these topics and many others are carefully described and discussed, mostly at a non-specialist level readily accessible to any physicist. The anecdotal remarks are usually illuminating, often amusing, and only occasionally do they tip over the top in a way that may irritate people outside the family. Anybody interested in low temperatures, or in the nature of the creative process in experimental science, or in the future of physics, should dip into *Near Zero*. They may find themselves reading more of it than they expect □

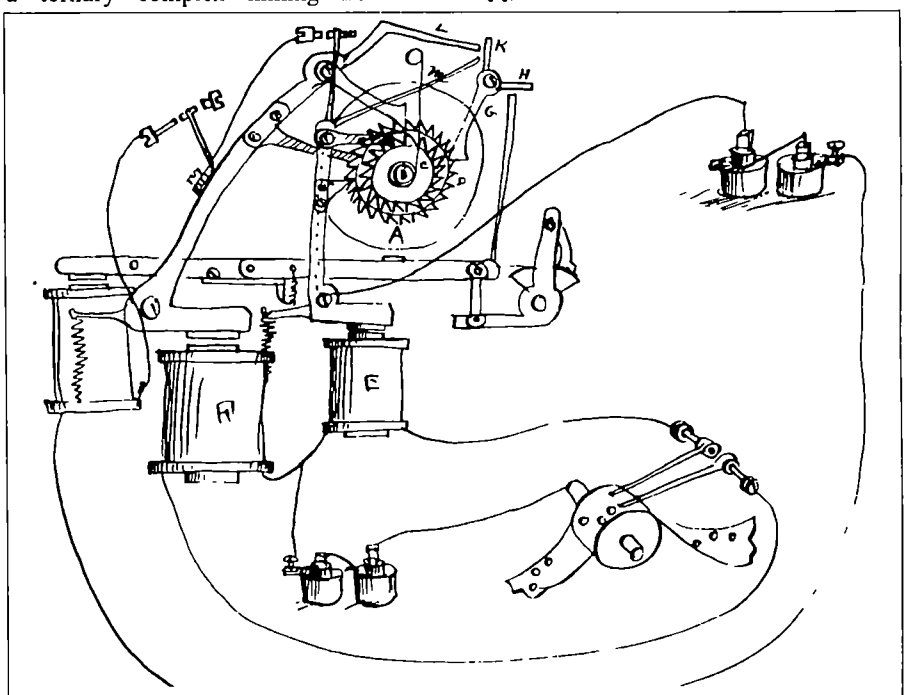
Biodigestion

John Edwards

A Guide to Modern Biology: Genetics, Cells & Systems. By Eleanor Lawrence. *Longman: 1989. Pp.507. Pbk £9.95, $29.95.*



THE "Modern Biology" of this volume, only partly revealed by its subtitle, is the biology of animal cells, especially where illuminated by recombinant DNA techniques. "Systems" are multicellular: immune, nervous, the developing animal and cancer. Together they claim almost half of the text. Eleanor Lawrence thus sets out single-handedly to tackle territory similar to that covered by six authors in Alberts *et al.*'s *Molecular Biology of the Cell*. She aims, however, to provide a quick reference source, and general introductory reading for the student or non-specialist.

Given the scale of the undertaking, I find that she has been remarkably successful — the key issues are strongly to the fore, essential terms are explained and some of the latest developments are deftly indicated. The crisp English makes for excellent readability. I particularly liked the perspectives in the introductory sections. The sparingly used, clear line diagrams have the virtue of simplicity, although a few carry jargon such as "CAP" and "BFU-E" which remains unexplained. Different views of the IgG molecule are poorly co-ordinated, and a ternary complex linking hormone receptor to adenylate cyclase gainsays its own legend. Both general and specific references will aid fast entry to the current literature, although they will date rapidly.

No one author could possibly be totally reliable and up-to-the-minute over such a broad canvas. I was unhappy with many odds-and-ends, both biochemical and cell biological (readers with other specialisms would presumably each find a different set of quibbles). To illustrate: there is a curious explanation of why self-splicing in *Tetrahymena* is not properly enzymic; a suspected misinterpretation of GAP with mutant Ras proteins; uncritical reference to the steric model of thin-filament regulation; KDEL but no RGD; and the assertions that all carcinogens are mutagens, and that tumour promoters act by stimulating proliferation of initiated cells. Writing perhaps finished before p53 changed sides from oncogene to anti-oncogene, and focal adhesions from movement to arrest.

We are all non-specialists in relation to some of this material. I believe many biologists will find this volume useful in the way the author intended. Undergraduates may value something easy to carry around, which could also teach them good writing. But for those to whom molecular cell biology is mostly new, the highly resourced artwork, illustrations and wider expertise to be found in a volume such as Alberts *et al.* are not to be missed. □

John Edwards is in the Department of Cell Biology, University of Glasgow, Glasgow G12 8QQ, UK.

Thomas Edison's sketch of "the printer which I propose to use for translating from the punched or embossed paper" in his "new system of telegraphy, using neither dots nor dashes" The drawing is reproduced from *The Making of an Inventor*, edited by R V Jenkins *et al.*, and published by Johns Hopkins University Press

Made to order

John Mann

The Logic of Chemical Synthesis. By E. J. Corey and Xue-Min Cheng. *Wiley: 1989. Pp. 436. $29 95, £19.15.*

THE structure elucidation of complex, biologically derived molecules has attracted the attention of organic chemists since the beginning of the nineteenth century. In contrast, the construction of these molecules has been solely a twentieth-century pursuit. Initially, the targets of these endeavours were relatively simple structures; even so, the syntheses were daunting given the paucity of starting materials and chemical reagents, and the complete absence of chromatographic and spectroscopic techniques.

Nevertheless, such complex molecules as quinine and haemin were synthesized before the Second World War. With the advent of increasingly sophisticated spectroscopic and chromatographic methods, and a new understanding of stereochemical principles and of electronic theories of mechanism, ever more challenging targets succumbed to synthesis. By 1960 the growing catalogue of achievements included syntheses of morphine, cortisone, strychnine, colchicine, penicillin V and chlorophyll.

All of these synthetic routes involved several steps, and some of them required heroic efforts in order to overcome poor-yielding stages. Although the routes were chosen after careful consideration of the starting materials available, and with a view to employing particular (often novel) reactions, there is little evidence to suggest that a systematic analysis of the target structures was carried out The syntheses were thus individual triumphs but not necessarily particularly efficient.

All this changed in 1967, following the publication of a seminal paper by E. J. Corey. He exhorted chemists to analyse their problems, and introduced the concept of retrosynthetic analysis. This involves 'transformation' of the target molecule into a synthetic precursor; and these 'transforms' are just the reverse of the potential synthetic operations. Because there are usually several possible precursors, and because these in turn have numerous other progenitors, a tree of potential intermediates is easily generated. Chemists are then required to exclude those transformations for which the synthesis would (in their opinion) be difficult or impossible. In this way, the shortest route from a cheap or readily available starting material can usually be found.

It would be misleading to suggest that it was Corey alone who invented retrosynthetic analysis; but he was the first to enunciate the general principles, and he went on to provide a comprehensive set of rules and regulations. The culmination of these enquiries into the logic of synthesis was the design of a computer programme, LHASA, which represents an automated version of the analytical process.

The book reviewed here provides the first full account of 20 years of retrosynthetic analysis. It is divided into three parts In the first 100 pages, the basic concepts and strategies are explained in full with numerous illustrative examples. This section could easily stand alone as a record of Corey's contributions to the logic of chemical synthesis. In the following 260 pages, retrosynthetic analyses (accompanied by actual synthetic schemes) are provided for 60 biologically derived molecules, and for just about all of the eicosanoids (prostanoids, leukotrienes and so on). All of the syntheses described were carried out by the Corey group. The final section includes a comprehensive literature survey of other multistep syntheses accomplished during the past 20 years.

On one level, the book undoubtedly represents a celebration of Corey's contributions to synthetic and retrosynthetic analysis — and why not! Few other synthetic chemists can claim to have devised and overseen the construction of so many interesting molecules. Some of the schemes have appeared in a similar form in other books (for example in A. Mitra's *The Synthesis of Prostaglandins* published by Wiley in 1977), but to have a full account of theory and practice in one place is invaluable.

This is an advanced-level volume and is not really suitable for undergraduate use. The methodology of retrosynthetic analysis is dealt with in a simpler fashion by Stuart Warren in *Organic Synthesis. the Disconnection Approach* (Wiley, 1982). But for anyone seriously involved in the art of organic synthesis, the book is a must — and a bargain. □

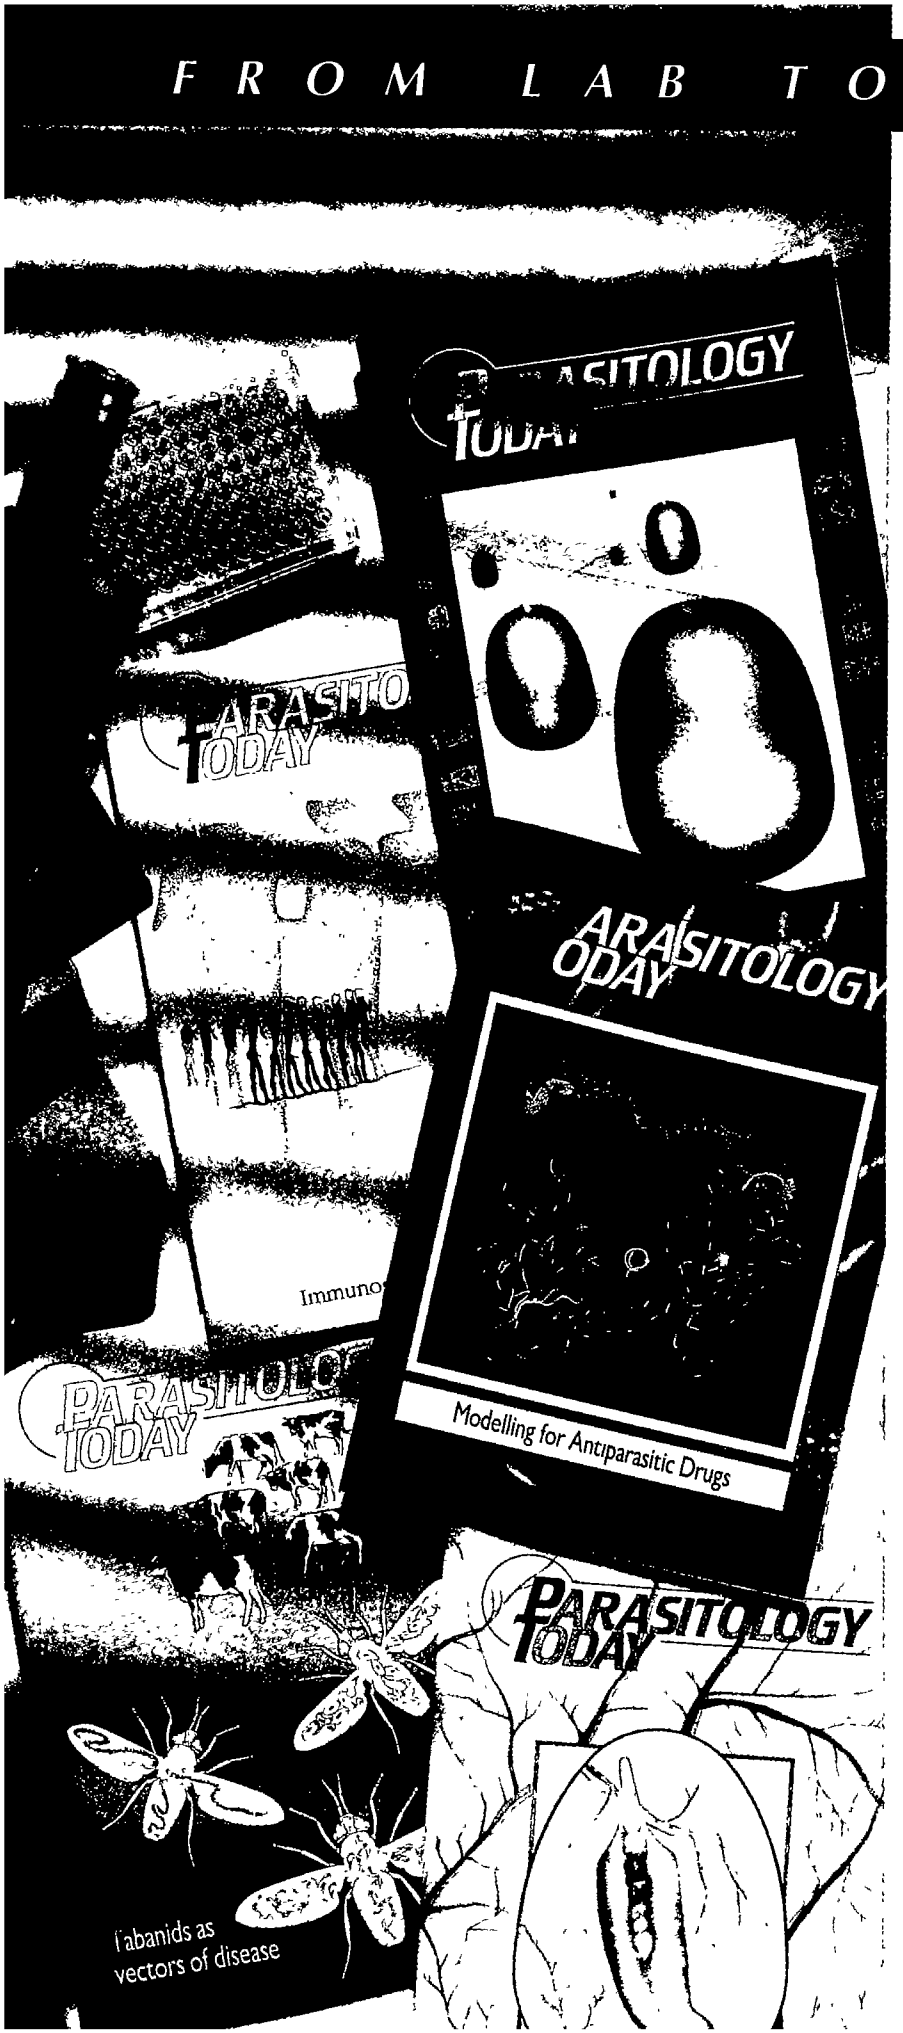
Rocky choices

K.G. Cox

Origins of Igneous Rocks. By Paul C. Hess. *Harvard University Press: 1989. Pp. 336 $65, £51.95.*

IGNEOUS rocks originate as melts in the hot interior of the Earth. They have been erupted or intruded in all geological periods in a great variety of environments, from rift valleys to mountain chains and the ocean floor. Their origins and evolution are highly complex and difficult to study, and it is a brave author who attempts to cover them comprehensively.

Origins of Igneous Rocks is, however, a worthy addition to the recently much-enlarged range of textbooks on this topic. Comparison is invited with A. McBirney's *Igneous Petrology* (Freeman, Cooper 1984), A. Hall's *Igneous Petrology* (Longman, 1987), and M. Wilson's *Igneous Petrogenesis* (Unwin Hyman, 1989). All of these books have a good deal of ground in common — we might ask, do we need a new one, and what is special about this one?



Hess's book is probably the most purely geochemical and theoretically petrological of the four. It has a more extensive section on phase diagrams than the others, and gives good theoretical coverage of magmatic differentiation, principles of geochemistry and the structure of silicate melts. The main part of the book follows the traditional pattern of discussing various rock-associations in sequence, and concludes with an excellent section on lunar petrology, which is not covered in competing works. Hess deliberately does not set out to discuss the more 'geological' aspects of the subject, such as igneous rock textures (well done by McBirney) or the forms of intrusions, volcanoes and so on (a strong suit in Hall).

Hess's problem was the sheer difficulty of covering a subject in which there is an immense amount of information about a bewildering variety of rocks, and that of relating the theoretical opening chapters to the subsequent discussion of natural rocks. It can be done, but not in 300 pages. Hess solves the first problem, as others often have, by being less than comprehensive in his examples. Intra-plate volcanism is represented almost entirely by Hawaii, continental flood basalts by the Columbia River province, continental rifts by East Africa, and so on. Wilson is much more comprehensive at this stage, but she devotes a much larger fraction of her book to it.

Like most other authors who have written on igneous petrology, Hess discusses and evaluates existing petrogenetic ideas about specific rock groups. He is particularly good at identifying outstanding questions and inviting readers to form their own judgement, but as a consequence at times can seem almost indecisive. Different authors all see things slightly differently, however, and this may be where the principal value of the new work lies. It contains little that is particularly novel, but it is highly competent and well written. Igneous petrology is a complex subject to become familiar with, and to have another view on most topics is of considerable value. □

FROM LAB TO FIELD

Parasitologists may have an interest in common, but the disciplines that they work within are as disparate as satellite sensing and molecular biology. This diversity reflects not only the challenge of experimental research in parasitology but also the global need to control major diseases like malaria, trypanosomiasis, leishmaniasis, schistosomiasis and filariasis.

Parasitology Today (PT) is the forum that unites review and discussion of current progress in all aspects of host/parasite relationships. It is the only monthly review journal that keeps specialists up-to-date in this complex and multidisciplinary subject.

PT - just one of the eight TRENDS journals from Elsevier. The others cover biochemistry and molecular biology, biotechnology, ecology and evolution, genetics and development, immunology, neuroscience, and pharmacology.

Thermodynamic cost of computation, algorithmic complexity and the information metric

W. H. Zurek

Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA

Algorithmic complexity is a measure of randomness. In contrast to Shannon's entropy it is defined without a recourse to probabilities; for a binary string s it is given by the size, in bits, of the shortest computer program with the output s. I show that algorithmic complexity sets limits on the thermodynamic cost of computations, casts a new light on the limitations of Maxwell's demon and can be used to define distance between binary strings.

REVERSIBLE computation can be accomplished only by using computer memory to keep track of the exact logical path from the input to the output. This conclusion[1-3], is based on the observation that thermodynamic irreversibility is inevitable only in presence of logically irreversible operations[4-6]. If several input states lead to the same output, the loss of information in such a many-to-one mapping makes it impossible reversibly to 'backtrack' the machinery of the computer. To allow reversible operation the computer must retain this additional information (the history of all the logically irreversible steps) at least temporarily, and it must retain at the end of the computation at least enough extra information to assure unambiguous backtracking[1,2,6,7]. Thus, reversible computation can be achieved only at the expense of filling up computer memory with historical records, aptly named 'garbage'[2,6].

But suppose one insists on replacement of the input with the output in the computer memory: How irreversible would the resulting computation be? This question about the 'replacement computation' leads to simple, yet interesting consequences, among them an information-theoretic measure of distance between binary sequences (which may represent physical configurations) or between statistically characterized ensembles. Thermodynamic efficiency of various information processing operations is of interest in physics of computation[1-9], and replacement computation is relevant for the foundations of thermodynamics[10].

Consider a simply describable universal computer C. Computations start with some program i as the input, and with the computer in a definite initial state. After the computer stops, only the output o should be present on the output tape and the computer should end up in some unique 'halting state.' As no permanent (only temporary) storage of 'garbage' is allowed, there is no possibility of retaining the history. In general, the computation of o from i will be logically and thermodynamically irreversible.

I shall demonstrate that the least increase of entropy $\delta S(i \to o)$ associated with the replacement depends on the input and output strings and is at least equal to the difference in length of the shortest programs i^* and o^* to compute i and o on C

$$\delta S(i \to o) \geq |i^*| - |o^*| \qquad (1)$$

Vertical lines denote the size of programs in the number of symbols. When the computer alphabet is binary the difference of entropy is given in bits.

Equation (1), the first main result of this paper, is derived below, where I also show that the optimum thermodynamic efficiency is difficult to attain: the minimal programs needed to guarantee it cannot be found systematically because of the undecidability of the halting problem—a Turing-machine version of Gödel's theorem.

The total amount of information exchanged in an update $s \to t$ (the minimal number of erased plus the minimal number of added bits needed to transform file s into file t) provides a natural measure of the information distance between two strings. I also show that this information distance satisfies conditions expected of a metric for both algorithmic and statistical measures of information content. Finally, discussion of the physical significance of the results shows how the logical irreversibility of replacement computations limits thermodynamic efficiency of Maxwell's demon. I propose that algorithmic complexity can be used to define the entropy from the point of view of the demon-like 'intelligent observer', in a manner that takes into account both the lack of complete information and the degree of randomness of the available data about the physical system.

Algorithmic information theory

Algorithmic randomness[11-22] of a string $K(s)$, also known as algorithmic complexity or algorithmic information content, is defined by the size of the minimal program s^* that, when executed on a universal computer, yields output s

$$K(s) \equiv |s^*| \qquad (2)$$

Any message can be represented as a binary string (a sequence of 0s and 1s), but some messages can be reproduced from more concise descriptions: a binary string consisting of 10^6 0s could not be printed in this paper but its content can be (indeed, already has been) communicated to the reader. By contrast, a typical random string of 10^6 0s and 1s obtained by flipping a coin cannot be compressed to a similarly concise description. Incompressible strings are called algorithmically random, and strings that can be characterized by messages small compared to their length in bits are called algorithmically simple.

Equation (2) captures the intuitive difference between the information content and the size of a string (a universal computer is stipulated only to make the definition reasonably independent of the addressee of the message). A string that appears random may nevertheless have a concise description. Binary representations of π, or $\sqrt{2}$, are good examples of apparently random, but, in fact, algorithmically simple strings. In general, no algorithm can distinguish random from simple strings, a difficulty related to Gödel's undecidability[16-18,22]. As I show below, however, $K(s)$ can be estimated from above by a simple algorithm for any finite s. Moreover, most strings cannot be compressed, so the typical algorithmic randomness of a string is, to leading order, given by its length in bits $|s|$. For example, the algorithmic randomness of a natural number n is typically $\log_2 n$. Certain classes of string are algorithmically random or simple; readers are invited to demonstrate that minimal pro-

grams used in the definition of algorithmic complexity are algorithmically random.

As in Shannon's information theory, one can define algorithmic randomness for sets of strings. Joint algorithmic complexity of a pair of strings (s, t) is the size of the smallest program required to print them both on the output tape. It satisfies the 'commuting' property

$$K(s, t) = K(t, s) + O(1) \quad (3)$$

and the inequality

$$K(s, t) \leq K(s) + K(t) + O(1) \quad (4)$$

The error term of O(1) comes from the slight computer dependence of the algorithmic information content[13-19]. I shall henceforth omit O(1) and replace equality and inequality signs with their approximate versions ($= \to \simeq$; $\geq \to \gtrsim$, for example) to simplify the notation.

Conditional algorithmic information $K(s|t)$ is the size of the smallest program $q^*_{s|t}$ that can compute string s from the string t (or, equivalently, both s and t from t)

$$K(s|t) \equiv |q^*_{s|t}| \quad (5)$$

Conditional information will be central in our discussion. By analogy with the statistical information theory one would expect $K(s|t)$ to obey

$$K(s, t) = |t^*| + |q^*_{s|t}| \simeq K(t) + K(s|t) \quad (6)$$

This equation is satisfied, but only approximately[19]. Correction terms of order of $O(\log_2 K(t))$ may arise, with their exact form dependent on the adopted definition of $K(s|t)$. However, equation (6) will hold with no more than O(1) errors if, in addition to string t, one is willing to provide its algorithmic randomness $K(t)$ as the supplementary datum

$$K(s, t) \simeq |t^*| + |q^*_{s|t,K(t)}| \simeq K(t) + K(s|t, K(t)) \quad (6a)$$

Moreover, conditional algorithmic randomness of s given t^* (rather than simply t)

$$K(s|t^*) \equiv |q^*_{s|t^*}| \quad (5a)$$

also satisfies equation (6) without logarithmic errors[20]

$$K(s, t) \simeq |t^*| + |q^*_{s|t^*}| \simeq K(t) + K(s|t^*) \quad (6b)$$

Rigorous definition of algorithmic randomness imposes certain requirements on the properties of the minimal programs. In particular, it is convenient to require that minimal programs be self-delimiting[19-21]—they must contain no special symbol to mark their ends, and must therefore contain information about their size. For instance, algorithmic randomness of a typical string defined through a self-delimiting minimal program is given by $|s| + \log_2 |s|$, where the logarithmic term enters because of the necessity to communicate, in addition to the content of s, its size.

Reversibility of compression

What is the least thermodynamic expense of generating string s from its minimal program s^*? This question emerges in the context of compressing information. by definition, the minimal program s^* can be used to reproduce the more 'verbose' record s, so the operation of replacing s by s^* will preserve the content, but will free $|s| - |s^*|$ bits of memory.

I shall demonstrate that, given s^*, the replacement of s by s^* can be achieved reversibly, with no cost in terms of entropy increase. Note that a reversible program can compute s from s^* and in the process generate history $g(s^*, s)$, which allows it to backtrack from s to s^* reversibly. The process of getting rid of s and replacing it with s^* is:

- Initially, the computer memory contains s and s^*; The complete input consists of $\{s, s^*\}$.
- The reversible execution of s^* yields output s and history $g(s^*, s)$. The computer memory now contains two copies of s and $g(s^*, s)$, but does not contain s^*, which was used up, that is, transformed into s in a reversible computation.
- The newly generated string s can reversibly cancel the 'old' s: $(s, s \to 0 \ldots 0, s)$. This frees up $|s|$ bits, but to make this operation logically reversible one copy of string s must be retained[2]. The memory now contains string s and 'garbage' $g(s^*, s)$.
- Finally, the computation of s from s^* can be reversed. The computer has all the directions, $g(s^*, s)$, to undo the original computation of s from s^* reversibly.
- At the end of the operation the computer memory contains only s^*. With no loss of information content, and at no thermodynamic cost, $|s| - |s^*|$ memory bits were liberated.

The string substituting s did not have to be minimal, or even shorter than s: all that was needed was the assumption that the execution of the input s' results in the output s.[1,2,7]

Lemma 1—Program s', which generates string s as an output, can be used to reversibly erase s from the memory of the computer, $(s', s) \to s'$. Minimal program s^* can be employed in this manner to reversibly compress information contained in s.

The essential criterion that makes compression of s possible is that the information in s must be available in the form of some other string s'. So far, I have assumed that the concise s' was already available. To accomplish compression, this s' was used in an algorithm outlined in the proof of Lemma 1. But it is more natural to consider a computer that 'looks for' some convenient and concise s' given the original file s. Lemma 1 then sets the limit on the compressibility of s.

A simple instance of such compressibility occurs when there are two copies of s (ref. 2). Availability of a program s' generating s as an output can be regarded as equivalent to the availability of an implicit copy of s. One can also imagine a more complicated situation where the information needed to generate s resides in a collection of several strings s', s'', ... which jointly generate s.

The ability of one binary string s to share information content with another string t can be expressed in terms of mutual algorithmic information defined by[14,20]

$$K(s:t) = K(s) + K(t) - K(s, t) \quad (7)$$

Two strings are algorithmically independent when $K(s:t) \simeq 0$. Two copies of the same string are algorithmically redundant: $K(s:s) \simeq K(s)$. Moreover, string s is algorithmically redundant with respect to string t when

$$K(t) > K(s) \quad (8a)$$

and

$$K(s:t) \simeq K(s) \quad (8b)$$

or equivalently

$$K(s, t) \simeq K(t) \quad (8c)$$

In other words, s is algorithmically redundant with repect to t when it contains no additional information not already included in t. In this sense, the output must be redundant with respect to the input.

Reversibility of the replacement operation $(s', s) \to s'$ relies on redundancy of the output string s with respect to the input s'. Lemma 1 is an example of the more general fact established in ref. 1: if $s \to f(s)$ is an arbitrary computable function, operations $s \to (s, f(s))$ and $(s, f(s)) \to s$ can be carried out reversibly because the inputs and the outputs are mutually redundant. What is new here is the application: Lemma 1 uses algorithmic complexity to establish the limit on the thermodynamically reversible compressibility of information.

Is redundancy not just a necessary but also a sufficient condition for the reversibility of the replacement operation $(s', s) \to s'$? It is true that whenever $K(s', s) - K(s) \simeq 0$ there must exist, by definition of conditional algorithmic information, a short minimal conditional string $q^*_{s|s'}$ capable of turning s' into a

program with output s. But the existence of a concise program generating s does not guarantee its availability because minimal programs are not recursively computable functions of their respective outputs[13-20]. The possibility of a reversible compression of s into the s^* or the existence of $q^*_{s|s}$ thus establishes limits on thermodynamic efficiency, but does not guarantee that optimal efficiency can be attained. Nevertheless, the absolute thermodynamic cost of computations is of interest for the foundations of statistical mechanics and, as demonstrated in more detail below, can be settled through arguments involving existence rather than computability.

Thermodynamic cost of replacement computation

I now investigate the least thermodynamic price (the optimal attainable efficiency) of a general replacement computation $i \to o$. The output is redundant with respect to the input, and therefore typically contains less information. The replacement computation of o from i thus disposes of some information, and must be logically irreversible. These logically irreversible steps can be either 'paid for' at once, the history of the computation being erased as the computation is carried out, or reversibly recorded, which delays thermodynamically costly erasures until after the computation is completed.

The cost of erasures will not increase if they are delayed by making a record $g(i, o)$ of all the irreversible steps and erasing it after the computation is completed—a bit of information is erased at the same cost regardless of when the erasure is done. One can therefore consider reversible computations $i \to o, g(i, o)$ and, without loss of generality, establish the lower bound on their efficiency by finding the least thermodynamic cost of erasure of $g(i, o)$ in the presence of o. Because the history will be generally algorithmically non-random and may contain information already present in the output, any concise program $q_{\iota|o}$ that can reproduce i from o and thereby reconstruct the history $g(i, o)$ can be also used, by Lemma 1, to reversibly compress $g(i, o)$. This line of reasoning can be developed into:

Theorem 1—The thermodynamic cost of computation which turns input i into output o, retaining no memory of i or of the intermediate steps cannot be made lower than

$$\delta S(i \to o) = K(i|o) \tag{9}$$

where $K(i|o)$ is the size of the minimal conditional string $q^*_{\iota|o}$.

The proof is accomplished by contradiction. Let the history $\tilde{g}(i, o)$ allow computation of o from ι, and suppose that it contains fewer than $K(i|o)$ bits, $|\tilde{g}(i, o)| < K(\iota|o)$. Then $\tilde{g}(\iota, o)$ could be used to reproduce i from o with a program shorter than the minimal conditional program $q^*_{\iota|o}$, which is impossible. Therefore $q^*_{\iota|o}$, containing $K(\iota|o)$ bits, is the shortest possible record of the history.

Erasure of the conditional string cannot be accomplished at a cost of less than $\delta S(i \to o) = |q^*_{\iota|o}|$ bits of entropy, which demonstrates Theorem 1. It also establishes:

Corollary—There exists an abbreviated version $q^*_{\iota|o}$ of the history of the computation $\iota \to o$ with $K(i|o)$ bits. It is typically much shorter than the original history $g(i, o)$ but, like g, it enables ι to be computed from o and can hence be used to reversibly reconstruct g itself. Unlike g, however, it is not necessarily computable from the input.

Uncomputability means that although Theorem 1 and its corollary establish a firm lower bound on the size of the history and demonstrate that this bound can be (not by recursive computation, but perhaps by sheer luck) actually met, they offer little help in the task of minimizing thermodynamic expenditures.

The lower bound of Theorem 1 can be used to derive equation (1), a slightly weaker but more direct bound expressed in terms of the algorithmic complexities of ι and o. Because the output is redundant with respect to the input, $K(i, o) \simeq K(i)$, and from equation (6a), $K(i|o, K(o)) \simeq K(\iota) - K(o)$. The size of the minimal program that computes i from o alone cannot be less than $K(i) - K(o)$; $K(i|o) \geq K(i|o, K(o))$, so:

Lemma 2—The thermodynamic cost of a replacement computation is greater than the difference in the algorithmic information content between input and output

$$\delta S(i \to o) \geq K(i) - K(o) \tag{10}$$

This simple equation gives the lower bound in terms of the individual complexities of the two strings. Moreover, it is the absolute limiting efficiency for the case when o^*, the minimal program for the output, is at hand. This follows from equation (6b) for the conditional information given o^*: $K(i|o^*) \simeq K(i) - K(o)$ without logarithmic corrections.

The disadvantage of equation (10) is that it is in general somewhat weaker than Theorem 1, which contained directly the size of the minimal conditional string. The reason for this slight difference touches some of the fascinating (and somewhat paradoxical) aspects of algorithmic information theory. Consider computation of a string s from its minimal program s^*. The algorithmic randomness of s and s^* is almost ($\sim$O(1)) identical: $K(s) = |s^*|$. Moreover, s^* is algorithmically random, as the reader verified above. Hence, the shortest program needed to obtain s^* cannot be shorter than $K(s)$. In addition, it cannot be longer than $K(s)$ by more than a few bits, as it must be shorter than the binary version of 'Print s^*'. Consequently, $K(s) \simeq K(s^*)$. Yet, s^* cannot be computed from s in a finite number of steps because of gödelian undecidability[16-18,22].

This comment should not be misunderstood. It is not difficult to suggest a concise and straightforward method of finding the shortest program that will generate string s within a pre-determined (arbitrarily large, but finite) number of steps N. One can test on C all of the conceivable programs (all the strings) shorter than the binary version of some program that obviously generates s. ($s_p \equiv$ Print s with the self-delimiting correction, if necessary, would do the job.) The list

0, 1, 00, 01, 10, 11, 000, 001, 010, 011, 100, 101, 110, 111, . . .

of all binary strings shorter than $|s_p|$, which must include all candidate programs, is very large ($\sim 2^{|s_p|}$) but finite, and can be easily supplied by a concise algorithm.

Each of the candidate programs can be run for N steps in a finite time $\leq N \times 2^{|s_p|}$. Among the programs that have halted within N steps some may give an output s. The first of them in the lexicographic order, $\tilde{s}$, is easily identified, and if $\tilde{s} < s$ it can be used to accomplish a partial compression of the information. If none of the programs that have halted produces s, s_p is still the shortest known program to generate s, and information compression has not been found possible.

This algorithm can be implemented reversibly, so the thermodynamic cost of finding $\tilde{s}$ is, in principle, negligible. But this does not disprove the fundamental undecidability of the algorithmic randomness of binary strings[16-18,22], because the algorithm used to find $\tilde{s}$ is primitive recursive[23,24]; it must halt after a finite number of steps $\leq N \times 2^{|s_p|}$. Identity of $\tilde{s}$ with s^* could be established only in the $N \to \infty$ limit.

Indeed, if it were known beforehand which programs never halt, they could be eliminated from the lexicographic list. Now the shortest remaining program with output s would be guaranteed to yield the correct value of $K(s)$, and the minimal program s^* could be easily found. This clever plan cannot be used: Turing's halting theorem[25], the computer-theoretic equivalent of the Gödel's theorem, establishes that there is no way to distinguish halting from non-halting programs. Undecidability thus thwarts attempts to systematically derive, in a finite number of steps, the most efficient algorithm. Worse than that, the minimal thermodynamic cost of computation is given in terms of algorithmic complexities, which are themselves uncomputable. Not only is it impossible to find the best procedure for optimizing a computation, it is also impossible to find out how well one is doing.

Advance knowledge of the algorithmic complexity $K(s)$ of s would allow one to modify the search so that it would be

guaranteed to halt after a finite number of steps. A short program for s, equal in length to the minimal s^*, would therefore become recursively computable. The uncomputability of the optimal efficiency is thus essential for the consistency of the above arguments, but it remains true that infinite computations can discover minimal programs.

The optimal algorithm could conceivably be found quickly. The halting theorem does not disallow the best solution being found after a finite number of iterations. One might also find the best solution by a lucky guess. It is only certain that one will never know how lucky one was.

Although the optimally efficient algorithm cannot be systematically discovered, it is always possible to limit the number of the erased bits to the size of the input[1,2,7]

$$\delta S(i \to o) \leqslant |\imath| \tag{11}$$

This 'guaranteed efficiency' can be easily justified[1]: it is always possible to perform the computation $\imath \to o$, $g(i, o)$, duplicate o, and use $g(i, o)$ to reproduce i. One is now left with o and $\imath$. Erasure of i can always be carried out at the cost of $|\imath|$ bits, so the thermodynamic cost can always be limited to no more than $|i|$ bits.

Although the δS guaranteed by equation (11) is somewhat trivial, there are instances when it coincides with the lower bound given by Theorem 1 and Lemma 2. For example, replacement of a random string with an equally long string of zeros cannot be carried out at a price lower than the guaranteed efficiency, equation (11).

These results complement and extend the proof[1] that a computation can be always performed reversibly[1-3,5-9] by establishing the minimal price of such reversibility for replacement computations. The price is given by the algorithmic complexity of the history of the computation given its output. Retaining $g(\imath, o)$ or i, leaves one the option to undo the computation at no thermodynamic expense. Erasing the history and the input incurs at least $\delta S(i \to o) \simeq |q^*_{\imath|o}| \geqslant K(\imath) - K(o) = |\imath^*| - |o^*|$ of entropy increase.

One might argue that the distinction between these two options—erasure and storage—is artificial: erasure can be accomplished by storing the relevant information in a physical system outside the computer memory. This point of view, which identifies increase of entropy with the erased information, must be further extended in a discussion of an update. Consider two files, s and t, each containing some information not present in the other $K(s) \neq K(s:t) \neq K(t)$. To compute t from s one must supply conditional information $K(t|s)$. A replacement computation requires erasure of the spurious information $K(s|t)$.

It is natural to count the thermodynamic cost of the supplied information with the opposite sign from the cost of the erased information. This leads to the net flow of algorithmic information between the computer and the rest of the Universe

$$\delta K = K(s|t) - K(t|s) \tag{12}$$

which (with the logarithmic correction terms) could be reduced to the right hand side of equation (10). But δK cannot immediately be identified with the minimal dissipation. The arguments of ref. 4 imply only that erasure of information is associated with an increase of entropy. δK would be a valid expression for the thermodynamic cost of an update only if the transfer of information from outside the computer caused a corresponding decrease of entropy. This assumption may be not unreasonable, (acquisition of information can be regarded as a measurement, and measurements are thought to decrease statistical entropy) I shall not attempt to discuss conditions for its validity here Moreover, neither of the two ingredients of δK is recursively computable, so the actual net number of transferred bits could be larger or smaller than δK. Thus, these arguments do not allow δK, equation (12), to be regarded as a minimal thermodynamic cost in the sense of equation (1) and Theorem 1.

I shall return to the thermodynamic significance of replacement computation later, in a discussion of measurements and the laws of thermodynamics. A more complete analysis of related issues can be found in ref. 10.

Algorithmic distance and the information metric

The extent of the update can be measured by the least amount of information involved in transforming s into t. Instead of counting the $K(s|t)$ and $K(t|s)$ with signs that depend on the direction of their flow between C and the rest of the Universe, as was done to obtain equation (12), one can add them to establish the total amount information needed to carry out the replacement. This sum defines the information distance between s and t

$$\Delta(s, t) \equiv K(s|t) + K(t|s) \tag{13a}$$

Algorithmic information distance can also be approximately expressed as

$$\Delta'(s, t) \equiv K(s) + K(t) - 2K(s:t) \tag{13b}$$

$$\equiv K(s, t) - K(s:t) \tag{13c}$$

$$\equiv 2K(s, t) - K(s) - K(t) \tag{13d}$$

The equality between $\Delta(s, t)$ and $\Delta'(s, t)$ would be exact only if equation (6) were satisfied exactly. For statistical (Shannon) entropy, analogues of Δ and Δ' are identically equal, but logarithmic correction terms in the algorithmic version of equation (6) imply similar (logarithmic) corrections going from the original definition, equation (13a), to its alternatives, equations (13b-d). One could get rid of these corrections by using one of the alternative but less natural definitions of conditional algorithmic information (equation (6a) or (6b)).

The information-theoretic quantity $\Delta(s, t)$ defined by equation (13a) satisfies the three conditions required to allow its use as a distance; (i) positivity

$$\Delta(s, t) \geqslant 0 \tag{14}$$

with the equality holding only when $s = t$, (ii) symmetry

$$\Delta(s, t) = \Delta(t, s) \tag{15}$$

and (iii) the triangle inequality

$$\Delta(s, t) + \Delta(t, u) \geqslant \Delta(s, u) \tag{16}$$

which follows from noting that the conditional minimal program $q^*_{u|s}$ for computing u from s cannot be longer than the program that computes u from s using t (that is, the concatenated program $q^*_{u|t}q^*_{t|s}$). Consequently

$$K(u|t) + K(t|s) \geqslant K(u|s) \tag{17a}$$

The same argument holds for computation of s from u. Thus

$$K(t|u) + K(s|t) \geqslant K(s|u) \tag{17b}$$

Addition of these two inequalities with the help of equation (13a) yields the triangle inequality, equation (16). Hence:

Theorem 2—Information distance $\Delta(s, t)$ provides a metric for the space of binary sequences.

Another proof of the triangle inequality, more immediately applicable to the statistical (Shannon) version of the information distance, follows from

$$K(s, t, u) \geqslant K(s, u) \tag{18}$$

Both sides of equation (18) can be multiplied by two, and after adding $K(s, t) - K(s, t) + K(t, u) - K(t, u) = 0$ to the left-hand side and subtracting $(K(s) + K(u))$ from both sides one arrives at $K(s|t, u) + K(t|s) + K(t|u) + K(u|s, t) \geqslant K(s|u) + K(u|s)$. Now, ignoring the usual logarithmic correction terms and using the fact that the left-hand side of the above inequality cannot decrease if $K(s|t, u)$ and $K(u|s, t)$ are exchanged with $K(s|t)$ and $K(u|t)$, respectively, leads to the triangle inequality in the

form in which Δ is expressed through conditional information, equation (13a).

All the steps of this second proof apply, without any logarithmic corrections, to Shannon's entropy H of classical ensembles, S, T and U. There is then no difference between Δ and Δ', and the distance given by any of the versions of equation (13) provides a metric for a collection of statistical ensembles characterized by their probability distributions. But it should be noted that the 'self-evident' inequality, equation (18), should not be taken for granted: it is not satisfied for statistical entropy H for systems that exhibit non-separable quantum correlations.

It is not difficult to show that $\Delta(s, t)$ satisfies the inequality $K(s, t) \geq \Delta(s, t) \geq |K(s) - K(t)|$. Obvious applications of the information distance include characterization of the relationship of the probability distributions. To some degree, mutual information has been already employed in that role[26]. Algorithmic-information distance is perhaps less immediately applicable to practical issues, but its fundamental implications may be far-reaching.

Complexity, Maxwell's demon and entropy

We have found that replacement computation can be done at a thermodynamic expense (an increase of entropy) greater than or equal to the difference in the algorithmic randomness between input and output. Entropy increase is thus a direct consequence of the decrease in the algorithmic information content. So far, this relation has been applied to set the thermodynamic limit on the reversibility of replacement computation. But there is also an inverse problem: what limits on statistical mechanics and thermodynamics can be found from algorithmic concepts? This is discussed in detail elsewhere[10]; here, I shall briefly outline the basic argument to provide physical motivation for interest in algorithmic randomness.

Consider a computerized engine consisting of a physical system in contact with a thermal reservoir at temperature T and controlled by universal computer C. The system is initially described by some density matrix ρ. Its standard ensemble entropy, measured in bits, is given by

$$H(\rho) = -\mathrm{Tr}\, \rho \log_2 \rho \tag{19}$$

The computer initiates a cycle of the engine by performing a dissipationless measurement[2,10,27] on the system. (In the context of quantum theory this implies that the measured observable must commute with the entropy, a condition which is always satisfied in the classical context.) Each of the outcomes, which are assumed to be mutually exclusive, is described by a density matrix ρ_k and occurs with probability p_k, so that $\rho = \Sigma_k p_k \rho_k$. The entropy of each outcome $H(\rho_k)$ is smaller than $H(\rho)$, and the average decrease of entropy is equal to

$$\langle \Delta H \rangle = H(\rho) - \sum_k p_k H(\rho_k) = -\sum_k p_k \log_2 p_k \tag{20}$$

The computer can convert this gain of information into useful work, at no thermodynamic expense, by constraining the system to the part of the phase space that coincides with ρ_k. Subsequently, useful work

$$\Delta W^+ = T(H(\rho) - H(\rho_k)) = T\Delta H_k \tag{21a}$$

could be extracted by allowing the constraint to relax in a slow isothermal fashion, so that ρ_k is transformed into ρ (Boltzmann's constant $k_B = 1$). The cycle can be repeated. If the process were truly cyclic, it would result in a violation of the second law by allowing an average gain $T\langle \Delta H \rangle$ of useful work per cycle. Szilard's engine provides a gedanken experiment realization of this idea[2,27-29].

Although the computerized "Maxwell's demon" can seemingly extract useful work, the second law of thermodynamics is not in danger. The cycle is never completed[2,10,27-29], as the memory of the computer does not return to its initial state: useless information about the outcomes of the past measurements piles up. The process uses computer memory as a zero-entropy reservoir. To make the process truly cyclic, the memory has to be periodically erased, and the cost of erasure must be subtracted to calculate the actual amount of useful work extracted. When the data is not random, a 'smart' erasing mechanism can take advantage of the regularities and compress the information before the erasure, whereas a 'dumb' erasing mechanism incapable of information compression would have to use $k_B T$ of work per bit, regularities notwithstanding. Data compression can be done separately, however, before the result is passed on to the 'dumb' erasing mechanism. One can thus separate reversible compression from the final irreversible erasure, and the cost of erasure can be in principle made as low as $k_B T$ times the algorithmic information content, rather than size in bits, of the record in question. This efficiency is attained by prior maximum (reversible) compression of the data to be erased (that is, in case of the computerized demon, of the conditional information $K(\rho_k|\rho)$). From Theorem 1 and Lemma 2, the thermodynamic cost of the most efficient erasure cannot be less than

$$\Delta W^- \simeq T\Delta K_k, \tag{21b}$$

where $\Delta K_k = [K(\rho) - K(\rho_k)] < 0$ is the difference between the algorithmic information content of the initial state and of the measurement outcome k.

Here I have used the version of the lower limit, $\delta S(\rho_k \to \rho) = K(\rho_k) - K(\rho)$, appropriate for a computation starting with the description of ρ_k as the input and ending with the minimal description of ρ as the output. This shows that even if the demon was able to guess minimal programs, it would still not endanger the second law. Without minimal descriptions, the cost of erasure would increase and the efficiency would decrease. The second law is therefore satisfied for computer-operated engines independently of the issue of computability, but uncomputability of minimal strings will cause additional dissipation.

The increase in the potential to do useful work as a result of the information gain[10] must be measured not just by the decrease in the ensemble entropy ΔH_k, but by the sum of ΔH_k and ΔK_k, which gives the least number of bits needed to write down the outcome of the measurement. The net amount of work that can be gained following measurement with the outcome k is

$$\Delta W_k = \Delta W_k^+ + \Delta W_k^- = T(\Delta H_k + \Delta K_k) \tag{22}$$

Consequently, what determines the net amount of extractable work is the sum of the usual ensemble entropy, which specifies the missing information, plus the algorithmic randomness of the available information[10]

$$\mathcal{S} = H + K \tag{23}$$

Physical entropy $\mathcal{S}$ extends the applicability of arguments based on entropy beyond the usual ensemble setting by allowing discussion of definite outcomes of measurements and their consequences[10]. In the usual limit it is dominated by the ensemble Boltzmann-Gibbs-Shannon component H. When the state of the system is known sufficiently well, however, algorithmic randomness K supplies the key contribution. Moreover, only when this state is algorithmically simple can one extract a sizable amount of useful energy.

The second law formulated in terms of physical entropy, equation (23), holds even during the measurements because the average information gain $\langle \Delta H \rangle$ is offset in $\mathcal{S}$ by the least average size of the code $\langle \Delta K \rangle = \Sigma_k p_k \Delta K_k$ required to specify the outcome. Information and coding theory implies that[30,31]

$$\langle \Delta H \rangle \leq \langle \Delta K \rangle \tag{24}$$

So, recording the outcome of the measurement performed on a system in a thermodynamic equilibrium will, on the average, use up at least as many memory bits as the corresponding decrease of ignorance ΔH. Fluctuations with $|\Delta K_k| < \Delta H_k$ are possible, but they occur sufficiently infrequently that equation

(24), and the second law formulated in terms of $\mathcal{S}$ are satisfied for the ensemble. Erasure of information can be represented, in terms of the $\mathcal{S}$, as the act of storing the information from the memory of the computer in some external system. This point of view was mentioned earlier.

Theorem 1 establishes an interesting connection between algorithmic complexity and the thermodynamic depth recently proposed as a measure of complexity[32]. Thermodynamic depth of an object o is the amount of information discarded in course of the process that led to its formation. As defined, thermodynamic depth is a function of a specific history[32], but it is of interest to define a minimal thermodynamic depth that is solely a function of the initial conditions i and of the final result o. Theorem 1 demonstrates that such minimal thermodynamic depth is given by the size of the smallest program that can reconstruct i from o and is closely approximated by the difference of their algorithmic information contents. Further discussion of the applications of algorithmic concepts to complexity can be found in ref. 33.

Conclusions

The central idea in this paper is a computational counterpart of the second law of thermodynamics. A computation that replaces the input (program) file with the output causes an increase of entropy by no less than $\delta S(i \to o) \simeq |q^*_{i|o}| \geq K(i) - K(o)$ bits, where $q^*_{i|o}$ is the minimal conditional string, the shortest conceivable version of history of the logically irreversible transformation $i \to o$. This implies that a compression of information, replacement of a file s with a known program $\tilde{s}$ that computes s, can be accomplished reversibly, and could save as much as, but no more than $|s| - K(s)$ bits of memory.

The second law of algorithmic dynamics sets limits on the efficiency of Maxwell's demon: Even if the demon could acquire the relevant information about the state of the physical system without dissipation, and correctly guess the most concise method of representing its knowledge, the necessity to periodically erase from its memory the records of 'used up' past measurements implies that at least $\delta S \geq K(\text{measurement outcome}) - K$ (initial state) bits would have to be erased in each successful cycle. This logical irreversibility of replacement computations is enough to guarantee the safety of the second law of thermodynamics even in the presence of information gathering and utilizing systems.

The demon's inability to circumvent the second law by any combination involving measurements and computation is especially obvious when the process of energy extraction is discussed in terms of physical entropy defined as a sum of known disorder (measured by the algorithmic randomness) and remaining ignorance (measured by Shannon's entropy).

Smoluchowski[34], in his discussion of the famous 'trapdoor' (an automated version of Maxwell's demon) showed that "no automatic, permanently effective perpetual-motion machine" can violate the second law by taking advantage of statistical fluctuations, but he suggested that "such device might perhaps function if it were operated by intelligent beings".

I have demonstrated that the second law is safe even from 'intelligent beings', as long as their abilities to process information are subject to the same laws as these of universal Turing machines. (This is the so-called 'Church-Turing thesis', which can be succinctly restated as[24] "What is human-computable is also machine-computable".) Moreover, it is unlikely that a demon dealing with an equilibrium system will 'break even', because optimal efficiency of replacement computations can be attained only with the necessary minimal programs (s^*, $q^*_{i|o}$, for example). Unfortunately, minimal programs cannot be systematically computed—Turing's halting theorem implies that the information required to attain maximum efficiency can be secured only through an infinitely long computation. Thus, Gödel's undecidability can be regarded as an additional source of dissipation.

Algorithmic distance between binary strings can be defined as a difference between their joint and mutual complexities. It has all the properties required of a metric. Moreover, an analogous formula—the difference between Shannon's joint entropy and mutual information—can be used to define distances between statistical ensembles. □

Protein folding in mitochondria requires complex formation with hsp60 and ATP hydrolysis

Joachim Ostermann, Arthur L. Horwich*, Walter Neupert & F.-Ulrich Hartl

Mitochondrial heat-shock protein hsp60 functions in the folding of proteins imported into mitochondria. Folding occurs at the surface of hsp60 in an ATP-mediated reaction, followed by release of the bound polypeptides. We propose that hsp60 catalyses protein folding.

NEWLY synthesized cytosolic precursors of mitochondrial proteins have to maintain an unfolded conformation to be competent for membrane translocation[1,2]. This is probably achieved by interaction with heat-shock proteins of relative molecular mass 70,000 (70K) in the cytosol and by the action of other factors which might include ATP-dependent 'unfolding enzymes'[3-9]. Precursors traverse the mitochondrial membranes in an extended conformation at translocation contact sites between the outer and inner membranes[10-14]. Amino-terminal presequences are cleaved by a matrix-localized, metal-dependent processing enzyme[15-17]. Proteins remaining in the matrix compartment then have to refold, and in many cases to assemble into supramolecular complexes. The precursors of a number of proteins of the intermembrane space are re-exported across the inner membrane, and follow an evolutionarily conserved assembly pathway of procaryotic origin[18,19]. These proteins probably have to remain in a more loosely folded conformation in the matrix before the second membrane-translocation event.

Little is known about how proteins fold inside cells. The mechanisms underlying the folding and assembly of proteins imported into the mitochondria are now a focus of interest. The recently identified stress protein, hsp60, is the first mitochondrial component known to be essential in these processes[20,21], which were previously assumed to occur spontaneously[22]. Hsp60 is a nuclear-coded, constitutively expressed heat-shock protein residing in the mitochondrial matrix as an oligomer of 14 subunits[23,24]. The hsp60 equivalent has been detected in mitochondria from several sources, including those of human cell lines[25-27]. Together with the structurally related *Eschericia coli* heat-shock protein groEL and the α-component of the Rubisco subunit-binding protein, hsp60 belongs to a subclass of molecular 'chaperones' termed 'chaperonins', which are components assisting in oligomeric protein assembly by an unknown mechanism[25,28,29]. The consequences of loss of hsp60 function have been analysed in a temperature-sensitive lethal yeast mutant defective in the gene coding for hsp60[20]. Mutant cells are deficient in the assembly of several mitochondrial proteins of the matrix, inner membrane and intermembrane space. For example, the precursor of the β-subunit of F_1-ATPase is imported into the mutant mitochondria, but fails to assemble into the F_oF_1-ATPase. Proteins of the intermembrane space, such as cytochrome b_2, which after import into the matrix have to be re-translocated across the inner membrane, do not reach their target compartment.

Using mitochondria as a model 'cell', we investigated whether the folding of imported proteins *per se* and not only the assembly of subunits into supramolecular complexes could be mediated by proteins such as hsp60. Here we describe details of the molecular folding of proteins transported into the mitochondrial matrix. At low temperatures, after depletion of mitochondrial ATP, or after treatment of mitochondria with *N*-ethylmaleimide, the precursor of a mitochondrial fusion protein is translocated across the mitochondrial membranes but does not assume a folded conformation. Intermediates arrested in the unfolded state are associated with hsp60 in a high-molecular weight complex. At least partial folding occurs in an ATP-dependent reaction at the surface of hsp60 before release. Essentially the same pathway is followed by authentic mitochondrial proteins. We conclude that (re)folding of proteins after translocation across the mitochondrial membranes requires a proteinaceous machinery in the matrix: hsp60 is identified as an essential component of this machinery which appears to fulfill the function of an ATP-dependent 'folding catalyst'.

Folding intermediates

To analyse the pathway of (re)folding of newly imported proteins, we used a mitochondrial precursor protein whose state of folding could be monitored by virtue of its resistance to protease. We made use of the fact that the cytosolic enzyme dihydrofolate reductase (DHFR) retains its enzymatically active conformation and folds as an independent, highly protease-resistant unit when fused to the pre-sequence of a mitochondrial precursor[13,30]. The fusion protein preSu9-DHFR proved to be a suitable construct: it consists of amino-acid residues 1-69 of the precursor of *Neurospora* F_o-ATPase subunit 9, joined to the amino-terminus of the complete mouse DHFR by three linker residues[31]. The 66-amino acid presequence is cleaved in two steps by the mitochondrial processing peptidase[32,33]. Unfolding of the DHFR moiety is the rate-limiting step for the transport of similar fusion proteins across the mitochondrial membranes[13,34]. To achieve rapid membrane translocation, radiolabelled preSu9-DHFR was precipitated from a reticulocyte lysate with ammonium sulphate, and the precipitate dissolved in 8M urea. After dilution in the import incubation, this precursor is rapidly translocated into mitochondria from *N. crassa* in a membrane-potential-dependent manner. Imported precursor was processed to the mature form, which corresponds to the complete DHFR carrying six additional residues at the amino-terminus. To determine the kinetics of refolding, import reactions were terminated after a short incubation by addition of uncoupler with immediate cooling. Precursor associated with the surface of mitochondria was removed by treatment with proteinase K. The mitochondria were then permeabilized by digitonin and the state of folding of the imported protein assayed by measuring the protease-resistance of its DHFR component. About 90% of the preSu9-DHFR contained in the reaction is translocated into mitochondria within 45 s at 25 °C (Fig. 1*a*), but only 30% of the imported protein reaches the stably folded, protease-resistant conformation. After three minutes, 70% of the imported protein has folded. Lowering the temperature considerably slows down the refolding and proteolytic processing of imported Su9-DHFR,

although the efficiency of membrane translocation is unchanged (Fig. 1*b*).

In these experiments, the organelles were energized for import by the addition of NADH, which in mitochondria of *N. crassa* and yeast is directly channelled into the respiratory chain, resulting in the production of ATP. Does the folding of imported proteins require energy in the form of ATP? We incubated isolated mitochondria in the presence of apyrase, an ATP- and ADP-hydrolysing enzyme from potato. Under these conditions, the urea-denatured precursor is readily translocated into mitochondria. The DHFR component of the imported protein, however, remains sensitive towards digestion with protease, indicating that the refolding reaction is largely inhibited (Fig. 1*c*). Results were similar when import was performed in the presence of the non-hydrolysable ATP analogues, AMP-PNP and AMP-PCP (AMP-PNP = adenosine-5′-(β,γ-imido)-triphosphate AMP-PCP = adenosine-5′-(β,γ-methylene)-triphosphate) (Fig. 1*d*). The non-hydrolysable ATP analogues compete with endogenous ATP present in the energized mitochondria. (In contrast to the previous view, membrane translocation of the precursor is not obligatorily coupled with its immediate refolding inside the mitochondria). Folding of the imported protein in the matrix is mediated by an ATP-dependent reaction.

Association with hsp60

Are the folding intermediates associated with a matrix component(s) during the folding reaction? PreSu9-DHFR was imported into mitochondria and digitonin extracts containing 70–90% of the soluble matrix marker fumarase and corresponding amounts of the imported protein were analysed on Sephacryl S-300 sizing columns. Matrix extracts of mitochondria incubated for import for 5 min at 25 °C in the presence of ATP contain the mature-sized fusion protein, which fractionates with a molecular weight corresponding to the monomer (Fig. 2*a*; i): the DHFR part of the monomeric Su9-DHFR has reached its protease-resistant conformation. About 10% of the protein in the extract migrates as a high-molecular-weight complex of ~700K. This material represents unfolded, or at least incompletely folded, fusion protein which is sensitive to protease. In extracts of ATP-depleted mitochondria, up to 60% of the protein is recovered in these high-molecular weight fractions (Fig. 2*a*; ii). This material is highly sensitive to protease (Fig. 4*c*). No more than 1% of the radiolabel contained in Su9-DHFR is detectable on 17.5% polyacrylamide gels as distinct proteolytic fragments. An antibody directed against denatured DHFR precipitated the protease-sensitive Su9-DHFR as efficiently as the SDS-denatured fusion protein, but did not recognize the folded monomeric form (not shown). Unfolded Su9-DHFR accumulated in the presence of AMP-PNP was also recovered in the high-molecular weight column fractions (Fig. 2*a*; iii).

It seems that the folding intermediates are probably associated with a complex which participates in the ATP-dependent folding reaction. The digitonin extracts analysed on Sephacryl columns contained ~80% of the total hsp60 present in mitochondria. This hsp60 behaves as a high-molecular weight complex which cofractionates with the incompletely folded intermediates of imported Su9-DHFR (Fig. 2). By contrast with the cofractionating Su9-DHFR, the hsp60 scaffold itself is largely resistant to digestion by protease, although a small fragment of 1-2K is cleaved by proteinase K from either the N-or C-terminus of the hsp60 subunits (Fig. 2*a*; iv). This does not result in the dissociation of the hsp60 oligomer, which we have demonstrated by re-chromatography of the protease-treated column fractions (not shown).

Authentic mitochondrial proteins such as the Rieske iron sulphur (Fe/S) protein of complex III and the β-subunit of F_1-ATPase ($F_1\beta$) also form a high-molecular weight complex in the matrix. Fe/S protein imported into apyrase-treated mitochondria is readily extractable with digitonin (Fig. 2*b*), unlike the protein that is assembled into complex III when imported in the presence of ATP[18]. The Fe/S protein contained in the extracts cofractionates exactly with hsp60. Essentially the same result is obtained when $F_1\beta$ is imported: the precursor

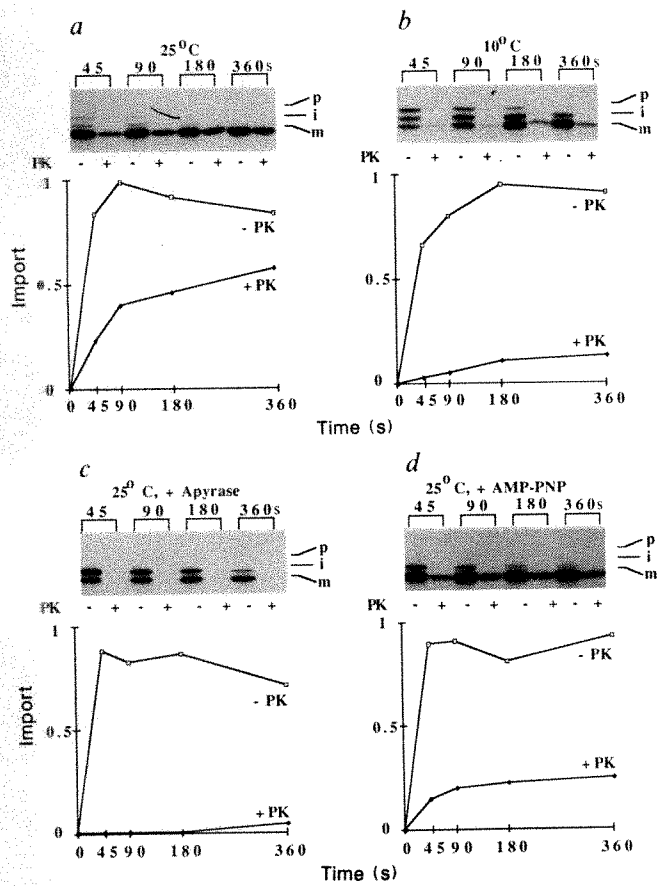

FIG. 1 Import into isolated mitochondria and refolding of Su9-DHFR. Isolated mitochondria were incubated under various conditions in the presence of preSu9-DHFR. Import (arbitrary units) at *a*, 25 °C; *b*, 10 °C; *c*, 25 °C into mitochondria treated with apyrase; *d*, 25 °C in the presence of 5 mM AMP-PNP. Upper panels, fluorographs of SDS-polyacrylamide gels of digitonin-permeabilized mitochondria previously incubated in the presence (+PK) or in the absence of proteinase K (−PK). *p*, Precursor; *i*, intermediate; *m*, mature-sized form of Su9-DHFR. Lower panels: amount of total imported and protease-resistant Su9-DHFR, as determined by densitometry of the fluorographs.

METHODS. Pre-Su9-DHFR was synthesized in a reticulocyte lysate in the presence of [^{35}S]methionine by transcription/translation of the complementary DNA cloned into expression vector pSP6 (refs 31, 47 and 48). Precursor was precipitated with ammonium sulphate at 66% saturation (30 min at 0 °C) and the precipitate was dissolved in 8 M urea/10 mM Tris, pH 7.5. Denatured precursor was diluted 20–40-fold into import reactions containing 3% BSA, 70 mM KCl, 2.5 mM $MgCl_2$, 2 mM NADH, 10 mM MOPS (3-[N-morpholino] propanesulphonic acid), pH 7.2, and 0.8 mg ml^{-1} isolated mitochondria of *N. crassa*, which were essentially free of cytosolic and endoplasmic reticulum markers[18,19]. Before addition of preSu9-DHFR and NADH, reaction *c* was incubated for 15 min with apyrase (40 U per ml final concentration; Sigma grade VIII)[31] and reaction *d* was incubated with 5 mM AMP-PNP. After incubation at 25° (*a*, *c* and *d*) or 10 °C (*b*) for the times indicated, import reactions were cooled on ice and diluted 5-fold with ice-cold SEM-buffer (0.25 M sucrose, 1 mM EDTA, 10 mM MOPS, pH 7.2) containing 8 μM antimycin A and 20 μM oligomycin, then treated with 25 μg ml^{-1} proteinase K for 10 min at 0 °C. After addition of 1 mM PMSF (phenylmethylsulphonyl fluoride), mitochondria were re-isolated by centrifugation[18] and resuspended at 0.5 mg ml^{-1} in 0.3% digitonin in SEM/100 mM KCl. Half of each reaction was treated with 10 μg ml^{-1} proteinase K for 10 min at 0 °C. PMSF was added and trichloroacetic acid precipitates analysed by SDS-polyacrylamide gel electrophoresis SDS-PAGE, fluorography and densitometry[15,19,49].

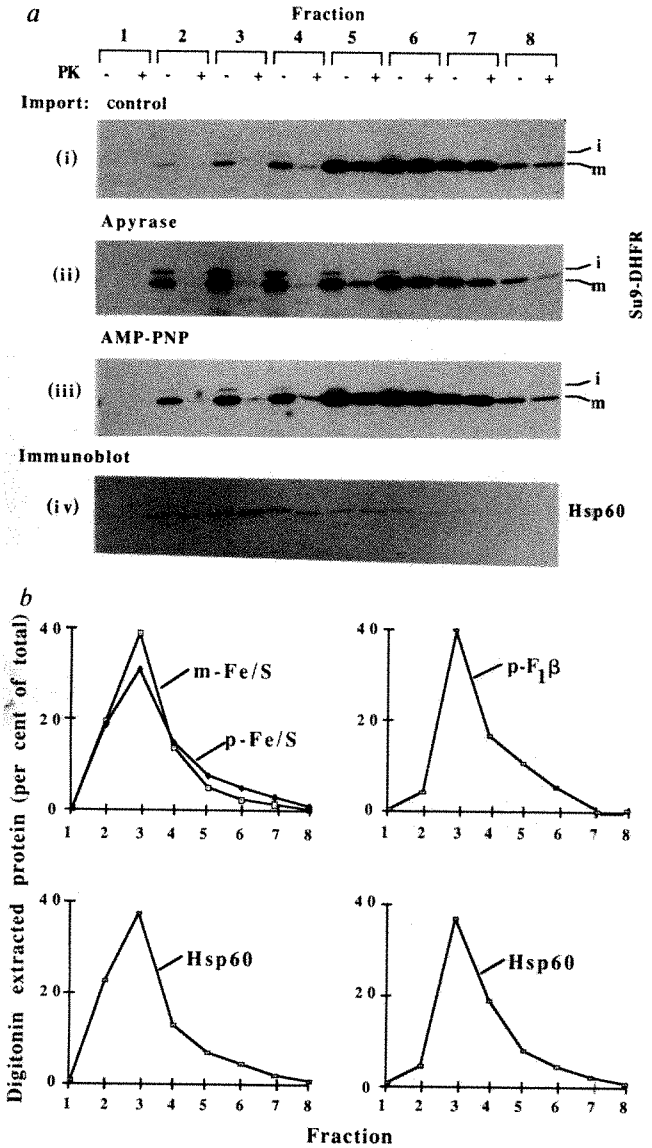

FIG. 2 Gel chromatography of folding intermediates. *a*, Analysis by Sephacryl S-300 chromatography of digitonin extracts prepared from mitochondria which had been incubated for import of preSu9-DHFR: (i) in the presence of ATP; (ii) after depletion of ATP with apyrase; (iii) in the presence of AMP-PNP (iv) Nitrocellulose blot of column fractions decorated with anti-hsp60 antiserum. Fractions of panel (ii) are shown representatively. Column fractions were analysed for total content in Su9-DHFR (−PK) and in protease-resistant Su9-DHFR (+PK). *b*, Gel chromatography of a digitonin extract from apyrase-treated mitochondria which had imported the precursor of Fe/S protein or of $F_1\beta$, respectively. Imported protein and hsp60 are shown as per cent of total protein in digitonin extracts.

METHODS. Import of urea-denatured precursor proteins into isolated mitochondria and protease-treatment of mitochondria are described in Fig. 1. Incubation for import was for 5 min at 25 °C. Matrix was extracted by incubating reisolated mitochondria for 1 min at 0 °C in SEM containing 0.3% digitonin. The concentration of mitochondrial protein was 5 mg ml^{-1} (ref. 18). After 5-fold dilution with SEM/100 mM KCl, reactions were centifuged for 10 min at 20,000*g*. Aliquots of pellets and supernatants were analysed for imported protein, hsp60 and the matrix marker enzyme, fumarase[33]. Supernatants were fractionated on 2.5 ml Sephacryl S-300 columns equilibrated with 100 mM NaCl, 10 mM Tris, pH 7.5. The void volume of the column was discarded and 200 μl fractions collected. The peak concentration of the 700K thyroglobulin marker was in fraction 3. Half of each fraction was treated with 10 μg ml^{-1} proteinase K for 10 min at 0 °C. Trichloroacetic acid precipitates were analysed by SDS-PAGE and fluorography, as well as by immunoblotting[50] with anti-hsp60 antiserum. Bound antibodies were detected by alkaline phosphatase[51] coupled to IgG directed against rabbit IgG (*a*; iv) or by ^{14}C-labelled protein A[15] (*b*). Fluorographs were quantified by densitometry.

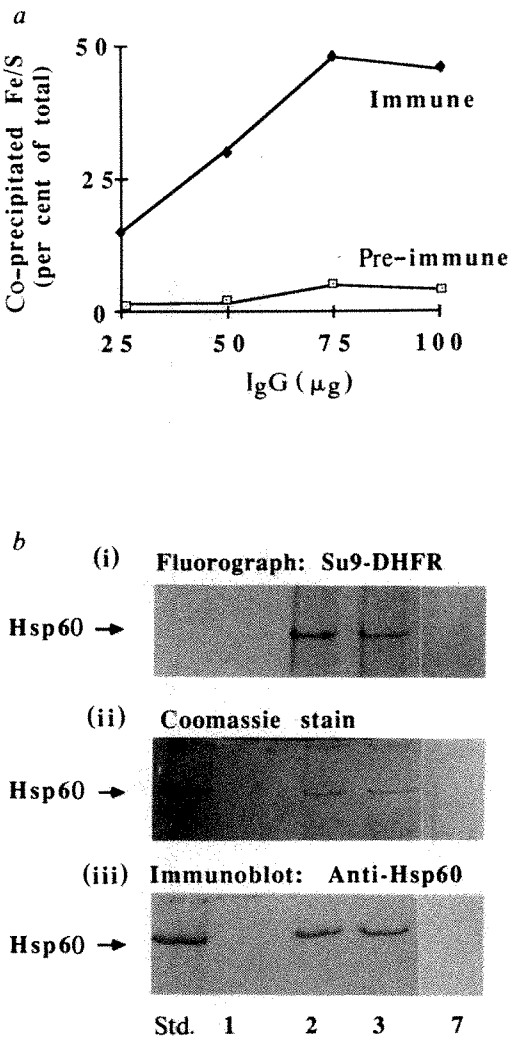

FIG. 3 Physical association of imported proteins with hsp60. *a*, Co-immunoprecipitation of Fe/S protein imported into apyrase-treated mitochondria with anti-hsp60 immunoglobulins. The amount of Fe/S protein (p-Fe/S plus m-Fe/S; compare Fig. 4*b*) precipitated from digitonin extracts are given as per cent of total Fe/S protein imported into mitochondria. The amounts of pre-immune and immune IgG indicated were preabsorbed to protein A-Sepharose. *b*, Non-denaturing polyacrylamide gel electrophoresis of Su9-DHFR–hsp60 complex partially purified by gel chromatography (corresponding to fractions 1–3 in Fig. 2*a*, ii). In addition, the monomeric fusion protein (fraction 7 in Fig. 2) was analysed. i–iii, Fluorograph, Coomassie blue stained and immunoblotted with anti-hsp60 antiserum, respectively. The position of a purified hsp60 standard (Std.) on the gel is indicated.

METHODS. *a*, Fe/S protein was imported into apyrase-treated mitochondria. Digitonin extracts were prepared (see legend to Fig. 2). Aliquots of the extracts corresponding to 25 μg intact mitochondria were added to protein A-Sepharose (PAS) pellets to which 25, 50, 75 and 100 μg preimmune- and hsp60 immunoglobulin had been preabsorbed, respectively[15]. Reactions were incubated for 30 min at 4 °C by rotating end-over-end in the presence of 1 mM PMSF and 30 μg m^{-1} protease inhibitor from *N crassa*[33]. PAS beads were pelleted and washed twice with SEM/KCl buffer and once with 30 mM Tris, pH 7.4. Wash solutions also contained protease inhibitors. PAS-immunoglobulin-antigen complexes were dissociated in SDS-containing buffer[15] and analysed by SDS-PAGE, fluorography and densitometry. The total amount of imported Fe/S protein contained in the extract was determined by immunoprecipitation with saturating amounts of anti-Fe/S immunoglobulin. *b*, Digitonin extracts of apyrase-treated mitochondria which had imported preSu9-DHFR were fractionated by gel chromatography. 50 μl aliquots of fractions 1–3 and of fraction 7 (see legend to Fig. 2) were loaded twice on the same 4–20% non-denaturing polyacrylamide gel[35]. Isolated hsp60 (1 μg) was analysed as standard. After electrophoresis, one half of the gel was blotted onto nitrocellulose and decorated with anti-hsp60 antiserum; the other half was stained with Coomassie blue and analysed by fluorography.

form accumulates in the apyrase-treated mitochondria and is detected as high-molecular weight complex (Fig. 2*b*).

We then demonstrated that the proteins imported at low levels of ATP are physically associated with hsp60. Fe/S protein was imported into apyrase-treated mitochondria, which were then extracted with digitonin. Monospecific immunoglobulins directed against hsp60 could co-immunoprecipitate up to 45% of the total Fe/S protein contained in the extracts (Fig. 3*a*). Comparable results were obtained with coprecipitation of Su9-DHFR (not shown), demonstrating that the column cofractionation of the imported proteins with hsp60 reflects a stable interaction between these components. Analysis of the high-molecular weight column fractions containing Su9-DHFR by non-denaturing gel electrophoresis[35] also indicated such an association. The protease-sensitive Su9-DHFR comigrated exactly with the hsp60 complex (Fig. 3*b*); between 50–70% of Su9-DHFR and hsp60 contained in the column fractions was recovered on the non-denaturing gel. The monomeric folded fusion protein was not seen as a distinct band.

Together our results indicate that proteins imported into the mitochondrial matrix transiently associate as incompletely folded intermediates in a high-molecular weight assembly complex before attaining their final, folded structure. Hsp60 is identified as a major constituent of this complex.

ATP-dependent folding and release

We investigated the ATP-requiring step in the sequence of reactions involved in folding imported proteins by adding back ATP to the hsp60-bound folding intermediates to see if they could be chased into the folded species. PreSu9-DHFR was imported into ATP-depleted mitochondria and matrix extracts were incubated with or without Mg^{2+}ATP. At low levels of ATP, about 60% of the imported fusion protein contained in the matrix extract remains protease-sensitive and cofractionates with hsp60 (Fig. 4*a*). In contrast, addition of ATP causes folding into the protease-resistant conformation and the release of Su9-DHFR from hsp60. The mature-sized protein fractionates as the monomer (Fig. 4*a*). The fractionation of hsp60 is unchanged. Apparently, the folding intermediates bound to hsp60 in the absence of ATP are productive intermediates on the authentic import pathway.

We also demonstrated this for the Fe/S protein associated with hsp60 in apyrase-treated mitochondria (Fig. 4*b*). Readdition of ATP to the intact mitochondria causes the release of

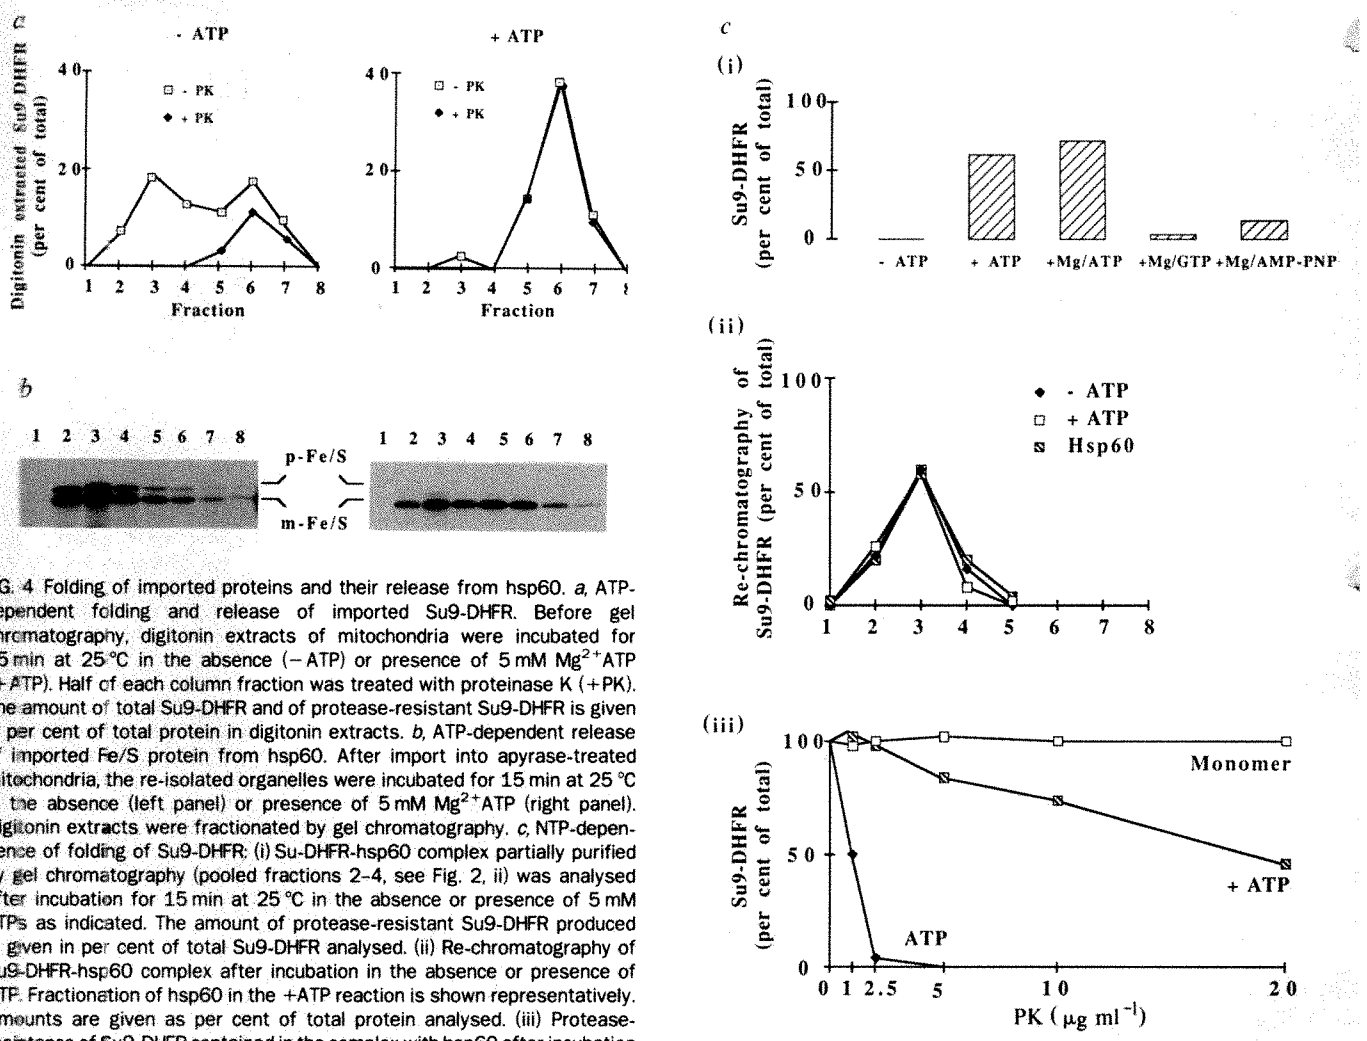

FIG. 4 Folding of imported proteins and their release from hsp60. *a*, ATP-dependent folding and release of imported Su9-DHFR. Before gel chromatography, digitonin extracts of mitochondria were incubated for 15 min at 25 °C in the absence (−ATP) or presence of 5 mM Mg^{2+}ATP (+ATP). Half of each column fraction was treated with proteinase K (+PK). The amount of total Su9-DHFR and of protease-resistant Su9-DHFR is given in per cent of total protein in digitonin extracts. *b*, ATP-dependent release of imported Fe/S protein from hsp60. After import into apyrase-treated mitochondria, the re-isolated organelles were incubated for 15 min at 25 °C in the absence (left panel) or presence of 5 mM Mg^{2+}ATP (right panel). Digitonin extracts were fractionated by gel chromatography. *c*, NTP-dependence of folding of Su9-DHFR: (i) Su-DHFR-hsp60 complex partially purified by gel chromatography (pooled fractions 2–4, see Fig. 2, ii) was analysed after incubation for 15 min at 25 °C in the absence or presence of 5 mM NTPs as indicated. The amount of protease-resistant Su9-DHFR produced is given in per cent of total Su9-DHFR analysed. (ii) Re-chromatography of Su9-DHFR-hsp60 complex after incubation in the absence or presence of ATP. Fractionation of hsp60 in the +ATP reaction is shown representatively. Amounts are given as per cent of total protein analysed. (iii) Protease-resistance of Su9-DHFR contained in the complex with hsp60 after incubation with or without ATP, and of the monomer Su9-DHFR obtained in *a*. Protein resistant to proteinase K at the concentrations indicated is shown as per cent of total protein. Equal amounts of labelled Su9-DHFR were analysed. METHODS. Import of precursor proteins into isolated mitochondria, preparation of digitonin extracts, gel chromatography and analysis of column fractions are described in the legend to Fig. 2. *c*, Column fractions 2–4 (see Fig. 2, ii) containing protease-sensitive Su9-DHFR exclusively, were pooled and divided into five 120 μl aliquots. Before incubation for 15 min at 25 °C, these reactions were made 5 mM in Na_2ATP, Mg^{2+}ATP, Mg^{2+}GTP or Mg^{2+}AMP-PNP using 100-fold-concentrated stock solutions in water adjusted to pH 7. Half of each reaction was treated with 10 μg ml^{-1} proteinase K for 10 min at 0 °C. Treatment with proteinase K for titration of protease resistance was under the same conditions. Trichloroacetic acid precipitates were analysed by SDS-PAGE, fluorography and densitometry.

60% of the hsp60-bound protein. Precursor is processed to m-Fe/S. Half of the released m-Fe/S is no longer extractable by digitonin and is recovered in the membrane fraction: probably this membrane-associated m-Fe/S is assembled into complex III[18]. The digitonin-extractable portion of the m-Fe/S that has been released from hsp60 migrates with a molecular weight of ~70K, which is higher than that expected for the monomeric Fe/S protein (25K). This m-Fe/S could represent protein not yet tightly assembled into complex III, or another matrix-localized intermediate on the assembly pathway. In contrast to the observations involving Su9-DHFR, ATP-dependent release of the Fe/S protein from hsp60 can only be demonstrated with intact mitochondria, and not with the matrix extracts containing the Fe/S-hsp60 complex. As the Fe/S protein has to be re-exported across the inner membrane, the inner membrane itself or a membrane-associated factor(s) could be required for its release from hsp60.

We investigated the nucleoside triphosphate specificity of the folding reaction using the Su9-DHFR-hsp60 complex from ATP-depleted mitochondria after its partial purification by gel chromatography. Aliquots were incubated for 15 min at 25 °C with and without NTPs (Fig. 4*c*; i). Addition of $Mg^{2+}ATP$ was most effective in promoting folding of the DHFR moiety, when about 60% of the total fusion protein remained resistant to proteinase K at 10 μg ml^{-1}. GTP and AMP-PNP were ineffective in promoting folding. In contrast to our results using total matrix extracts (Fig. 4*a*), the protease-resistant fusion protein still cofractionated with the hsp60 complex (Fig. 4*c*; ii) and could be co-immunoprecipitated by anti-hsp60 antibodies as efficiently as the unfolded fusion protein present in the absence of ATP (not shown). Titration with increasing concentrations of proteinase K revealed that this Su9-DHFR is less resistant to digestion than the monomeric fusion protein (Fig. 4*c*; iii). Several protease-resistant fragments accounting for ~10% of the radiolabel contained in Su9-DHFR were detected on SDS-polyaerylamide gels near the gel front (not shown). This indicates that ATP-mediated folding of the DHFR moiety is occurring at the surface of the hsp60 complex. It is possible that an hsp60 function necessary for release of the associated polypeptides is inactivated during gel chromatography or, more likely, that an additional component(s) of the mitochondrial matrix which does not cofractionate with hsp60 is necessary for the complete sequence of reactions leading to the folded monomeric protein.

NEM-sensitivity of folding

Is the folding of Su9-DHFR under physiological import conditions, that is, in the presence of intramitochondrial ATP, also dependent on protein factors? Using the membrane-permeant alkylating agent, N-ethylmaleimide (NEM), we found that modification of mitochondria with 1–5 mM NEM before import in the presence of ATP inhibited the refolding of imported Su9-DHFR into a protease-resistant conformation (Fig. 5*a*). Translocation of the urea-denatured precursor into the mitochondria and proteolytic processing were unaffected. NEM treatment does not cause depletion of ATP in the matrix compartment (see legend to Fig. 5). Interestingly, after short import incubation (2–5 min), Su9-DHFR can be extracted by digitonin and is associated with hsp60 (Fig. 5*b*), whereas in control reactions the protein is folded and exists as the monomer (Fig. 2*a*). But after incubation of the NEM-treated mitochondria for 15 min, most of the imported protein is no longer extractable and is recovered in the membrane fraction. This Su9-DHFR was still very sensitive to protease. Extractability of hsp60 was unchanged, indicating that Su9-DHFR had fallen off the hsp60 complex and was forming incompletely folded aggregates. After combined treatment with NEM and apyrase, readdition of ATP causes a shift of the protease-sensitive Su9-DHFR from the extractable complex with hsp60 into the membrane fraction (not shown). The aggregated fusion protein is slightly more protease-resistant than the polypeptides bound to hsp60 in the absence of ATP. Formation of insoluble aggregates of imported proteins, including a defect in the refolding of Su9-DHFR, was also observed in mitochondria of the hsp60-deficient yeast mutant, mif4 (not shown).

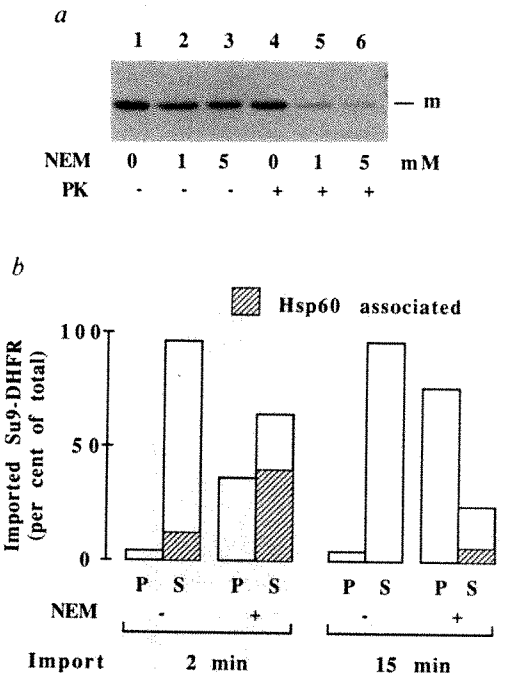

FIG. 5 Inhibition of folding in NEM-treated mitochondria. *a*, Import of preSu9-DHFR for 15 min at 25 °C into isolated mitochondria pretreated with NEM at the concentrations indicated. Mitochondria were permeabilized with digitonin and were incubated in the absence (lanes 1–3) or in the presence (lanes 4–6) of proteinase K. *b*, Extractability by digitonin of Su9-DHFR imported for 2 min or 15 min into control mitochondria and into mitochondria pretreated with 5 mM NEM. Extracts were separated into pellets (*P*) and supernatants (*S*). Supernatants were analysed by gel chromatography. Column fractions 3 and 4 containing the highest concentrations of hsp60-complex were pooled. Imported Su9-DHFR is given as per cent of total imported protein. The shaded area of the columns marked supernatant represents Su9-DHFR recovered in hsp60-containing column fractions.
METHODS. Mitochondria were incubated for 10 min at 25 °C at a protein concentration of 2 mg ml^{-1} in SEM-buffer containing 0, 1 or 5 mM NEM. Dithiothreitol was added to a concentration 5-fold higher than NEM and incubation continued for 5 min at 25 °C. Mitochondria reisolated by centrifugation were resuspended in SEM and used for import of Su9-DHFR as described in Fig. 1. Import reactions contained 2 mM $Mg^{2+}ATP$. Digitonin treatment, preparation of digitonin extracts and analysis on Sephacryl S-300 columns are described in the legends to Figs 1 and 2. Oligomycin-sensitive ATP hydrolysis of NEM-treated mitochondria was assayed: mitochondria were incubated as for import in the presence of 1 mM $Mg^{2+}ATP$ for various times at 25 °C either with or without 20 μM oligomycin and ATP in the mitochondrial supernatant was determined by coupled enzyme assay[52]. Compared with controls, NEM-treated mitochondria internalized and hydrolysed identical amounts of ATP.

We conclude that folding of the imported protein must be protein 'catalysed': folding at the surface of hsp60 and ATP-dependent release are two essential but separable steps necessary to achieve the final conformation. It remains to be tested whether hsp60 itself is the target of the NEM-effect. We have detected a reaction of hsp60 with ^{14}C-labelled NEM under conditions which inhibit folding (not shown).

Discussion

We have described here the surprising discovery that proteins imported from the cytosol into mitochondria do not refold spontaneously once translocation across the mitochondrial membranes is complete. The stress protein hsp60 residing in the mitochondrial matrix has been identified as a major component of an NEM-sensitive device involved in the folding of imported

proteins, which acts in conjunction with ATP. In the absence of ATP, newly imported proteins form a soluble complex with hsp60. Newly imported protein is associated in a loosely folded conformation, which is very sensitive to protease, with the surface of the hsp60 scaffold. ATP hydrolysis allows folding and release from hsp60, but our present data do not prove that this ATP effect(s) is exerted by hsp60 itself. On the other hand, ATP-dependent folding of the associated polypeptide occurs at the surface of hsp60 before release. It remains to be determined whether the release of the partially folded polypeptide from hsp60 has a direct ATP requirement, or whether it is merely a consequence of the preceeding ATP-dependent folding. One or more additional component(s) might be involved. Mitochondria could contain an equivalent to the groES protein, which in *E. coli* seems to cooperate with groEL in various assembly functions by an unknown mechanism[36–38].

How does hsp60 fulfil its function? A parallel study has shown that proteins traverse the mitochondrial membranes in an extended conformation (unpublished results). We propose that polypeptides entering the mitochondrial matrix have a conformation similar to nascent chains emerging from the ribosome, and that it is these unfolded polypeptides that interact with hsp60. This may even occur during translocation. Our results with the DHFR-fusion protein indicate that hsp60 is not specific for the structural motifs present in only mitochondrial proteins. Notably, urea-denatured DHFR, when part of a fusion protein, can refold spontaneously in appropriate buffer solutions[34], but, this does not happen after translocation across the mitochondrial membranes. The mitochondrial matrix is effectively a highly concentrated protein solution, which does not correspond to conditions frequently used in refolding experiments *in vitro*. It may be an essential function of hsp60 to capture the unfolded polypeptides entering the matrix and so prevent the formation of misfolded proteins. Cytosolic precursors of mitochondrial and secretory proteins interacting with 70K heat-shock proteins[3,4] have been proposed to bind through hydrophobic regions exposed in the newly synthesized, incompletely folded polypeptides[6,7,39,40]. The complex formed between hsp60 and imported polypeptides is only slightly destabilized by non-ionic detergents such as Triton X-100 (results not shown); this could indicate that here the interaction is not predominantly hydrophobic in nature.

The role of ATP in hsp60-mediated folding and release of the polypeptide is unclear. Although the chaperonins, including the mitochondrial hsp60, are structurally unrelated to the 70K heat-shock proteins, both groups of components exhibit weak ATPase activity[39–43]. It has been suggested that ATP hydrolysis causes a conformational change in 70K heat-shock proteins, which is transferred to the bound polypeptide[6,7,39,40,44]. An additional soluble factor seems to participate in these reactions[4,5,9]. So far, the function of the 70K proteins has been evident in stabilization of a loose, translocation-competent conformation of cytosolic precursor proteins, or the disruption of protein aggregates. In contrast, the mitochondrial hsp60 is essential for protein folding. ATP hydrolysis by hsp60 or by another component could loosen the association of the unfolded polypeptides with the hsp60 scaffold, and thus allow for their ordered, domain-wise folding at the surface of hsp60. We describe this type of reaction as 'protein-catalysed protein folding'; it may be slower than the 'spontaneous folding' that occurs in the mitochondrion in the absence of the functional folding 'catalyst' resulting in misfolded protein aggregates. Hsp60 and the homologous groEL protein of *E. coli* may have similar functions in folding nascent polypeptide chains synthesized in the mitochondrial matrix or in the bacterial cytosol. It is possible that protein folding in the eukaryotic cell cytosol or in other membrane compartments such as the endoplasmic reticulum, could also be protein-mediated.

The chloroplast Rubisco-binding protein and hsp60 were originally defined as components assisting in oligomeric protein assembly[20,21,25,28,29]. In the light of our results, these chaperoning reactions probably represent only a part of their function. The actual assembly reactions could occur spontaneously after folding of the subunits and their release from hsp60. Alternatively, complementary surfaces of subunits might be exposed only while the partially folded polypeptides are still in an assembly complex with hsp60. Likewise proteins such as the Riesks Fe/S protein or cytochrome b_2, which have to be re-exported from the matrix to the intermembrane space[18,19], could be shuttled to their respective protein export centres while associated with hsp60. A function for groEL in the stabilization of proteins for export across the bacterial plasma membrane has been suggested[45]. Other factors in the mitochondrial matrix, such as the recently described 70K protein SSC1[46], could also be involved in keeping proteins in a translocation-competent conformation.

Our findings concerning the function of hsp60 should have application in the renaturation by folding catalysts of proteins obtained by overexpression in bacteria, raising interesting possibilities for biotechnologists in the future. □

NEW FROM OXFORD

IMMUNOLOGY

Genetic Variants and Strains of the Laboratory Mouse

Second Edition

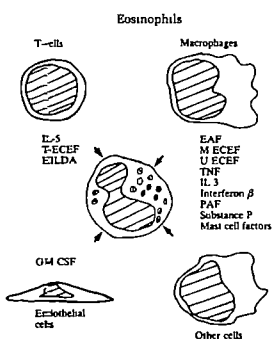
Edited by **Mary F. Lyon and Antony G. Searle**

This authoritative reference for information on mouse genetic and chromosomal variants describes all the known genes, and features a range of genetic maps. The second edition has several new chapters, and includes full nomenclature information.

0 19 854204 6, 912 pp., illus., 1989 £90.00

B Lymphocytes in Human Disease

Edited by **Graham Bird and Jane E. Calvert**



Antibodies and B-lymphocytes play a crucial role in the body's defences against infection, but also cause diseases. This volume provides an up-to-date discussion of the cellular and molecular biology of antibodies and the cells that produce them.

0 19 261573 4, 544 pp., illus., 1988 £60.00

Eosinophils

A Comprehensive Review and Guide to the Scientific and Medical Literature

Christopher J. F. Spry

Recent studies have shown how eosinophil blood cells respond to and take part in inflammation, damage parasites, and can often harm normal cells, especially in the heart. This book reviews the developments in the field and includes over 2000 references, forming the most thorough review of the literature currently available.

0 19 261408 8, 502 pp., illus., 1988 £50.00

The Epidemiology of AIDS

Expression, Occurrence and Control of Human Immunodeficiency Virus Type 1 Infection

Edited by **Richard A. Kaslow and Donald P. Francis**

This is the first comprehensive text on the epidemiology of AIDS and HIV infection. In a well-integrated and critical manner, it distills voluminous, widely dispersed research data on the AIDS phenomenon.

0 19 505058 4, 432 pp., illus., OUP USA, 1989 £35.00

Immunophysiology

The Role of Cells and Cytokines in Immunity and Inflammation

Joost J. Oppenheim and Ethan M. Shevach

This important new text describes the ways cells normally regulate immunological and inflammatory reactions, and discusses the ways the immune system is intimately related to other bodily functions.

0 19 505097 5, 450 pp., illus., OUP USA, October 1989 £75.00

Immune Responses, Virus Infections and Disease

Edited by **N. J. Dimmock and P. D. Minor**

This collection of conference proceedings discusses complex areas in immunology that have important clinical ramifications. Topics covered include influenza, polio, hepatitis B, and demyelinating encephalitis.

Special Publications of the Society for General Microbiology No. 27

0 19 963030 5, 200 pp., illus., IRL Press, 1989 £30.00 (tentative)
0 19 963031 3, paperback £20.00 (tentative)

Cytokines in Cancer Therapy

Frances R. Balkwill

Cytokines regulate cellular function, and may have a role in the mechanisms of cancer. This book presents for the first time basic research on these proteins and their current and potential clinical applications.

0 19 261797 4, 312 pp., illus., 1989 £30.00
0 19 261715 X, paperback £18.50

FORTHCOMING

Leucocyte Typing IV

White Cell Differentiation Antigens

Edited by **W. Knapp, B. Dorken, W. R. Gilks, P. Reiber, R. Schmidt, H. Stein, and A. von dem Borne**

This in-depth report on the experiments and analyses carried out for, and discussed at, the Fourth International Workshop on Human Leucocyte Differentiation Antigens presents the work of 525 laboratories which jointly evaluated and/or submitted about 1100 different monoclonal antibodies to human leucocyte surface molecules. The results of these collaborative experiments were reported at the meeting, compared, and summarized to produce a careful description of 89 human leucocyte antigens, 35 of them fully characterized for the first time. This book, which contains the first and only complete account of these experiments and analyses will become the standard reference work in the field. It will prove invaluable to immunologists, cell biologists, molecular biologists, haematologists, and pathologists for years to come.

0 19 261867 9, 1,100 pp., illus., January 1990 £90.00

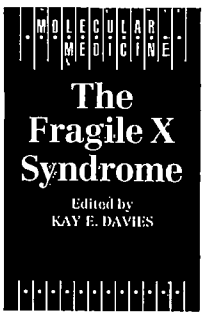
Cystic Fibrosis

Peter Goodfellow

Cystic fibrosis is the commonest autosomal genetic disorder in Caucasian populations. This book summarizes the modern treatment of cystic fibrosis and the results of clinical research. It explores its molecular genetics, and points the direction for future study.

Molecular Medicine Series

0 19 2618350, 112 pp., illus., paperback, 1989 £15.00



The Fragile X Syndrome

Edited by Kay E. Davies

The fragile X (Martin-Bell) syndrome is the most common genetic cause of mental retardation after Down's syndrome. This book reviews clinical, epidemiological, and cytogenic aspects of the disease.

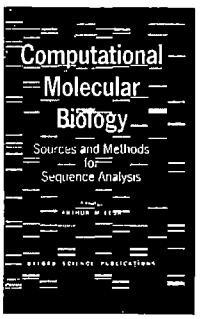
Molecular Medicine Series

0 19 261836 9, 148 pp., illus., paperback, 1989 £15.00

Syphilis Serology

Principles and Practice

Gerald D. Wasley and Helen H. Y. Wong



Clinicians rely on serology to aid the diagnosis and management of syphilis. Describing significant technological advances in the laboratory investigations of syphilis, this up-to-date textbook describes the tests, the principles behind them, and other aspects of diagnosis and control.

0 19 261530 0, 168 pp., illus., 1989 £20.00

Computational Molecular Biology

Sources and Methods for Sequence Analysis

Arthur M. Lesk

This book explores the emerging field of computing with protein and nucleic acid sequences. It looks at the available data, possible calculations, the accessibility of programs and data, and the interpretation of results.

0 19 854218 6, 266 pp., illus., 1989 £25.00

Human Monoclonal Antibodies

Current Techniques and Future Perspectives

Edited by **J. Brown**

Comprising the proceedings of the 1986 Monoclonal Antibodies in the Treatment of Human Disease symposium, this study presents papers which cover areas of basic research in human monoclonal antibody production, industrial production, and regulatory issues.

1 85221 024 9, 90 pp., paperback, IRL Press, 1987 £19.50

OXFORD UNIVERSITY PRESS

FRONTIERS IN MOLECULAR BIOLOGY

IRL PRESS at OXFORD UNIVERSITY PRESS

Designed to cover fast-breaking areas of molecular biology research, each book in this series presents informative chapters written by leading researchers who are specialists in their subject areas The books feature a carefully thought-out, integrated organizational plan and provide an up-to-date analysis of the topic in a readable, effective format *Frontiers in Molecular Biology* will prove to be an invaluable aid to all who require timely, original, and useful reviews of current research

Series Editors B D Hames and D M Glover

GENES AND EMBRYOS: FRONTIERS IN MOLECULAR BIOLOGY

Edited by D M Glover and B D Hames
Contents K V Anderson *Drosophila* the maternal contribution, M S Levine & K W Harding *Drosophila* the zygotic contribution, K J Kemphues *Caenorhabditis*, T D Sargent *Xenopus*, I J Jackson *The Mouse*
0-19-963028-3 232 pp, 46 illustrations IRL Press 1989 Hardback £27 00
0-19-963029-1 Paper covers £18 00

MOLECULAR NEUROBIOLOGY: FRONTIERS IN MOLECULAR BIOLOGY

Edited by D M Glover and B D Hames
Contents E Barnard Introduction, T Claudio Molecular genetics of acetylcholine receptor channels, B Ganetzky & C-F Wu Molecular approaches to neurophysiology in *Drosophila*, J Covault Molecular biology of cell adhesion in neural development
0-19-963042-9 170 pp, 7 halftones, 18 line illustrations IRL Press November 1989 Hardback £27 00
0-19-963043-7 Paper covers £18 00

ONCOGENES: FRONTIERS IN MOLECULAR BIOLOGY

Edited by D M Glover and B D Hames
Contents C J Marshall Oncogenes and cell proliferation an overview, G Peters Oncogenes at viral integration sites, T H Rabbitts & P H Rabbitts Molecular pathology of chromosomal abnormalities and cancer genes in human tumours, S I Rayter, K K Iwata, R M Sorvillo, D M Valensuela & J G Foulkes Biochemical functions of oncogenes, D P Lane Oncogenes of the DNA tumour viruses their interactions with host proteins
0-19-963034-8 250 pp, 18 line illustrations IRL Press November 1989 Hardback £27 00
0-19-963035 6 Paper covers £18 00

MOLECULAR IMMUNOLOGY: FRONTIERS IN MOLECULAR BIOLOGY

Edited by B D Hames and D M Glover
Contents T K Blackwell & F W Alt: Immunoglobulin genes, M M Davis T-cells antigen receptor genes, F Guillemot, C Auffray, H T Orr & J L Strominger MHC antigen genes, C Terhorst, B Alacon, J Devries & H Spits T-lymphocyte recognition and activation, K B M Reid The complement system
1-85221-079-6 260 pp, illustrations IRL Press 1988 Hardback £23 00
1-85221-075-3 Paper covers £15 00

TRANSCRIPTION AND SPLICING: FRONTIERS IN MOLECULAR BIOLOGY

Edited by B D Hames and D M Glover
Contents N B La Thangue & P W J Rigby *Trans*-acting protein factors and the regulation of eukaryotic transcription, A K Hatzopoulos, U Schlokat & P Gruss Enhancers and other *cis*-acting regulatory sequences, N J Proudfoot & E Whitelaw Termination and 3′ end processing of eukaryotic RNA, A R Krainer & T Maniatis RNA splicing
1-85221-080-X 212 pp, 22 line drawings IRL Press 1988 Hardback £23 00
1-85221-076-1 Paper covers £15 00

FORTHCOMING

DNA REARRANGEMENT: FRONTIERS IN MOLECULAR BIOLOGY

Edited by B D Hames and D M Glover
Contents Abbreviations, D E Berg Genomic rearrangements in prokaryotes, H T Van der Ploeg Antigenic variation in African trypanosomes genetic recombination and transcriptional control of VSG genes, G R Stark, M Debatisse, G M Wahl & D M Glover DNA amplification in eukaryotes Index
0-19 963050-X Approximately 200 pp, halftones, line drawings IRL Press December 1989 Hardback (provisional) £27 00
0-19 963051-8 Paper covers (provisional) £18 00

THE PRACTICAL APPROACH SERIES

New Spiralbound Format

With over 150,000 copies in circulation, the *Practical Approach* series is the premier source of detailed laboratory protocols Exploring a comprehensive range of techniques, experimental procedures, and theoretical findings, this series provides detailed, timely, and accessible data for bioscientists.

Starting in 1989, each *Practical Approach* title will be available in a new spiralbound hardcover format in addition to the paperback version These manuals will now lie flat on your work surface, allowing even easier access to the latest protocols

NUCLEIC ACIDS SEQUENCING: A PRACTICAL APPROACH

Edited by C J Howe and E S Ward

Contents Contributors, Abbreviations, Introduction, The use of single-stranded DNA phage in DNA sequencing, Sequencing single-stranded DNA using the chain-termination, Troubleshooting in chain-termination DNA sequencing, Sequencing of double stranded DNA, Maxam and Gilbert sequencing using one metre gel systems, RNA sequencing, Computing, Automated DNA sequencing

0-19-963056-9, 250 pp , illus , spiral bound, IRL Press, 1989 £27 00
0 19 963057-7, paperback £18 00

PROTEIN PURIFICATION METHODS: A PRACTICAL APPROACH

Edited by E L V Harris and S Angal

Contents Introduction, Extraction, Separation on the basis of structure , Separation by exploitation of activity, Separation on the basis of size

0 19 963002-X, 310 pp , illus , spiral bound, IRL Press, 1989 £30 00
0 19 963003-8, paperback £20 00

PROTEIN PURIFICATION APPLICATIONS: A PRACTICAL APPROACH

Edited by E L V Harris and S Angal

Contents Large scale purification, Purification of proteins for therapeutic use, Purification for crystallography, Purification of membrane proteins, Purification of proteins for sequencing, Engineering proteins for purification

0-19-963022-4, 200 pp , illus , spiral bound, IRL Press, 1989 £27 00
0-19-963023-2, paperback £18 00

Protein Purification Methods A Practical Approach, and Protein Purification Applications A Practical Approach, two-volume set

0-19-963048-8, illus , spiral bound, IRL Press, 1989 £48 00
0-19-963049-6, paperback £32 00

SOLID PHASE PEPTIDE SYNTHESIS: A PRACTICAL APPROACH

E Atherton and R C Sheppard

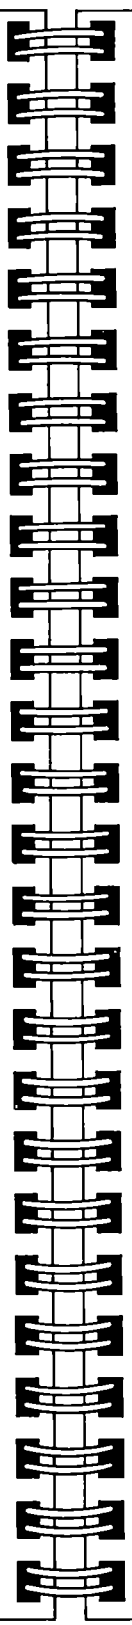
Contents Peptide synthesis—An introduction, Solid phase peptide synthesis—The Merrifield technique, Fmoc-polyamide solid phase peptide synthesis—General principles, The solid support, Fluorenylmethoxycarbonyl amino-acids, Linkage agents, Activation procedures, Instrumentation for Fmoc-polyamide solid phase synthesis, Analytical and monitoring techniques, Reaction procedures and operating techniques, Resin cleavage and purification techniques, Illustrative synthesis

0-19-963066-6, 250 pp , illus , spiral bound, IRL Press, 1989 £29 00
0-19-963067-4, paperback £19 00

PROTEOLYTIC ENZYMES: A PRACTICAL APPROACH

Edited by R J Beynon and Judith S Bond

Contents The diversity of proteolytic enzymes, Purification of proteolytic enzymes, Proteax assay methods, Determination of protease mechanism, Inhibition of proteolytic enzymes, Prevention of unwanted proteolysis, Proteases in peptide synthesis, Proteolysis of proteins for sequence analysis, Proteinase as probes of conformation, Proteases as membrane probes, Solubilization of membrane proteins, Exogenous control of catabolism, Proteases in protein maturation



0-19-963058-5, 270 pp , illus , spiral bound, IRL Press, 1989 £29 00
0-19-963059-3, paperback £19 00

LYMPHOKINES AND INTERFERONS: A PRACTICAL APPROACH

Edited by M J Clemens, A G Morris and A J H Gearing

Includes Induction, production and purification of murine gamma interferon, production of recombinant interferons by expression in heterologous mammalian cells, biological assays for interferons, cell growth inhibition by interferons and tumour necrosis factor, eosinophil differentiation factor and its associated B cell growth factor activities

1-85221-036-2, 392 pp , IRL Press, 1987 £33 00
1-85221-035-4, paperback £22 00

ANTIBODIES VOLUME I: A PRACTICAL APPROACH

Edited by D Catty

Contents Properties of antibodies and antigens, Production and quality control of polyclonal antibodies, Murine monoclonal antibodies, Human monoclonal antibodies, Immunoaffinity chromatography, Gel immunodiffusion, immunoelectrophoresis and immunostaining methods, Haemaglutination and haemolysis assays

0-947946-86-1, 208 pp , IRL Press, 1988 £29 00
0-947946 85-3, paperback, 1988 £19 00

ANTIBODIES VOLUME II: A PRACTICAL APPROACH

Edited by D Catty

Contents Antibodies in blood group serology, Antibodies in HLA serology, Immunoassays using radiolabels, ELISA and related enzyme immunoassays, Immunoperoxidase methods, Immunofluorescence, Fluorescence – activated cell sorting, Antibodies for tumour immunodetection and methods for antibody radiolabelling

0-19-963018-6, 278 pp , illus , IRL Press, 1989 £29 00
0-19-963019 4, paperback £19 50

PROTEIN STRUCTURE: A PRACTICAL APPROACH

Edited by T E Creighton

Includes SDS gel electrophoresis, isoelectric focusing, two-dimensional PAGE, immunological detection, peptide mapping, disulphide bonds, minimizing irreversible modification, predictions from gene and amino acid sequences, spectral methods, immunochemical analysis, folding proteins, measuring conformational stability

0-19 963000-3, 370 pp , illus , spiral bound, IRL Press, 1989 £30 00
0-19-963001-1, paperback £20 00

PROTEIN FUNCTION: A PRACTICAL APPROACH

Edited by T E Creighton

Includes Maintaining protein function, ligand protein binding affinities, ligand blotting, affinity labelling, cross-linking by disulphide bonds, competitive labelling, analysis, identification and purification of sequence specific DNA-binding proteins, chemical modification, site directed mutagenesis, determining roles of subunits

0-19-963006-2, 326 pp , illus , spiral bound, IRL Press, 1989 £29 00
0-19-963007-0, paperback £19 00

Protein Structure and Protein Function A Practical Approach Two volume set

0-19-963064-X, spiral bound, IRL Press, 1989 £50 00
0-19-963065-8, paperback £33 00

CELL GROWTH AND DIVISION: A PRACTICAL APPROACH

Edited by Renato Baserga

Includes Measuring parameters of growth, mouse embryo cells, C3H 10T1/2 and NIH3T3 cell lines, human leukemia cells, normal human epidermal keratinocytes and mesothelial cells, cloned T cell proliferation, muscle cell cultures, human diploid fibroblasts, cell synchronization, BALB/C-3T3 cells

0-19-963026-7, 172 pp , illus , spiral bound, IRL Press, 1989 £27 00
0-19-963027-5, paperback £18 00

LYMPHOCYTES: A PRACTICAL APPROACH

Edited by G G B Klaus

Includes Preparation of lymphocyte accessory cells, lymphocyte subpopulations, fractionation by immunomagnetic beads, induction and enumeration of antibody-forming cells *in vitro*, generation of human B lymphoblastoid cell lines using Epstein-Barr virus, biochemical characterization of lymphocyte surface antigens

1-85221-018-4, 284 pp , IRL Press, 1987 £27 00
1-85221-019-2, paperback £18 00

PROTEIN SEQUENCING: A PRACTICAL APPROACH

Edited by J B C Findlay and M J Geisow

Contents Protein and peptide purification, Peptide preparation and characterization, Automated solid phase microsequencing, Gas or pulsed-liquid phase sequence analysis, Sequencing by mass spectrometry, Manual methods of protein sequencing, Structure prediction

0-19-963012-7, 212 pp , illus , spiral bound, IRL Press, 1989 £27 00
0-19-963013-5, paperback £18 00

IRL PRESS at OXFORD UNIVERSITY PRESS

IN FOCUS

This new series of concise, to-the-point textbooks will give undergraduate and graduate students a grasp of the innovative areas of biochemistry and immunology—areas where updates are emerging freely and standard texts can often lag behind

Providing current research developments that can supplement both lecture and laboratory work, the *In Focus* series offers your students the very latest information formatted in high-quality yet affordable and easy-to-read texts. Thoroughly illustrated in two colours for clarity, and containing extensive reading lists for further study, *In Focus* textbooks will enhance your students' awareness of current developments

Series Editors D Rickwood, *Department of Biology, University of Essex*, and D Male, *Institute of Psychiatry, London*

ANTIGEN-PRESENTING CELLS: IN FOCUS

J M Austyn

Contents Immune recognition, Antigen presentation in immune responses, Accessory cells in culture, Antigen processing and immunostimulation, Accessory cells *In vivo*
0-19 963005-4, 90 pp, 9 halftones, 23 two-colour line drawings, IRL Press, 1989
Paper covers £6 50

ENZYME KINETICS: IN FOCUS

A Cornish-Bowden and C W Wharton

Contents Introduction, Abbreviations, Simple enzyme kinetics, Derivation of steady-state rate equations, Reactions of enzyme activity, Enzyme mechanisms
1-85221-074-5, 78 pp, 1 halftone, 20 line drawings (2 colour), IRL Press, 1988
Paper covers £6 50

MEMBRANE STRUCTURE AND FUNCTION: IN FOCUS

W H Evans and J M Graham

Contents General features and properties, Composition and structure, Membrane receptors, Membrane biogenesis and trafficking, Membrane channels and bioenergetics
0-19-963004-6, 98 pp, 25 two-colour line drawings, IRL Press, 1989
Paper covers £6 50

COMPLEMENT: IN FOCUS

S K A Law and K B M Reid

Published in association with the British Society of Immunology

Contents Complement, Activation and control of the complement system, Groups and families of proteins within the complement system, Role of complement in health and disease, Conclusion
1-85221-061-3, 82 pp, 26 two-colour line drawings, 4 halftones, IRL Press, 1988
Paper covers £6 50

IMMUNE RECOGNITION: IN FOCUS

M J Owen

Contents General principles of recognition, Immunoglobulin genetics and the generation of antibody diversity, The T-cell antigen receptor, T-cell recognition of antigen and MHC gene products
1-85221-062-1, 84 pp, 4 halftones, 16 two-colour line drawings, IRL Press, 1988
Paper covers £6 50

FORTHCOMING

GROWTH FACTORS: IN FOCUS

John K Heath

Proposed Contents The mammalian cell cycle, Identification and structure of growth factors, Growth factor receptors and signals, Growth factors and gene expression, Growth factors and transformation, Growth factors for haemopoetic cells, Mutants of the cell cycle
0-19-963041-0 Winter 1989 (tentative)

GENE STRUCTURE AND TRANSCRIPTION: IN FOCUS

T Beebee and J Burke

Contents Gene structure and transcription apparatus in prokaryotes, Regulation of transcription in prokaryotes, Gene structure and transcription machinery in eukaryotes, Regulation of transcription in eukaryotes
1-85221-014-1, 78 pp, 22 line drawings (2 colour), IRL Press, 1988
Paper covers £6 50

MOLECULAR BASIS OF INHERITED DISEASE: IN FOCUS

K E Davies and A P Read

Contents Recognising genes, Mapping and tracking genes, The identification of genes in inherited disorders, The molecular basis of human inherited disorders
1-85221-073-1, 88 pp, 25 two-colour line drawings, IRL Press, 1988
Paper covers £6 50

LYMPHOKINES: IN FOCUS

A S Hamblin

Published in association with the British Society for Immunology

Contents Lymphokines, Biochemistry of lymphokines, Lymphokines in the activation of T cells, B cells and macrophages, Lymphokines in haematopoieses, cytotoxicity and inflammation, Lymphokines in pathology and therapy, Endpiece The future for lymphokines
1-85221-055-9, 82 pp, 2 halftones, 26 two-colour line drawings, IRL Press, 1988
Paper covers £6 50

REGULATION OF ENZYME ACTIVITY: IN FOCUS

J H Ottaway

Contents Amplification, time scales and feedback, Theoretical aspects of the regulation of enzyme activity, Regulation by igand binding, Regulation by reversible covalent modification, Signals, transducers and modifiers, Regulation of enzymes in plants, Overview
1-85221-072-9, 88 pp, 1 halftone, 38 two-colour line drawings, IRL Press, 1988
Paper covers £6 50

GENETIC ENGINEERING: IN FOCUS

J Williams

Contents The enzymology of genetic engineering, *E coli* cloning vectors, Isolation of genes by molecular cloning, Gene analysis and manipulation
1-85221-071-0, 82 pp, 31 two-colour line drawings, IRL Press, 1988
Paper covers £6 50

FORTHCOMING

PROTEIN SYNTHESIS: IN FOCUS

H R V Arnstein and R A Cox

Proposed Contents Overview, Synthesis of aminoacyl transfer RNAs, The ribosome, The ribosome cycle, Post-translational modifications, Targetting of proteins to specific locations, Regulation of protein synthesis
0-19-963040-2 Winter 1989 (tentative)

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously

Nature is an international journal covering all the sciences Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields Please write clearly and simply, avoiding unnecessary technical terminology *Nature's* staff will edit manuscripts to those ends if necessary Contributors should check their proofs carefully

Because of the competition for space, many of the papers submitted for publication cannot be accepted For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words

CATEGORIES OF PAPER

Review Articles survey recent developments in a field Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator Length is negotiable in advance but must not exceed six pages of *Nature*

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications

Articles may contain a few subheadings of two or three words The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows There should be fewer than 50 references

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature* The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study Letters should not have subheadings or more than 30 references

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research Some are commissioned, most are unsolicited They are normally between one and four pages of *Nature* in length

News and Views articles are intended to inform non-specialist readers about a recently published advance Suggestions should be made to the News and Views Editor Illustrations are welcome Proposals for meeting reports should be agreed in advance

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature* Priority is given to contributions of less than 500 words and five references Figures are welcome

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only Four copies are required, each accompanied by lettered artwork Four copies of half-tones should be included Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number Original artwork should be unlettered Ideally, no figure should be larger than 28 by 22 cm Figures with several parts are permitted only if the parts are closely related, either experimentally or logically Suggestions for cover illustrations, with captions, are welcome Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published

Colour Artwork A charge of £500 a page is made for 4-colour figures Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible The figure should be described first, then, briefly, the method Reference to a method described elsewhere is preferable to a full description Methods should not be described in detail in the text

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate) Text should not be included in the reference list References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65) The first and last page numbers should be cited Reference to books should clearly indicate the publisher and the date and place of publication

Abbreviations, symbols, units and Greek letters should be identified the first time they are used Acronyms should be avoided as much as possible and, when used, defined Editors will shorten words if necessary In case of doubt, SI units should be used

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named

Acknowledgements should be brief Grant numbers and contribution numbers are not allowed

Submission All manuscripts may be submitted to either London or Washington They should not be addressed to editors by name Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT)

The asymmetric monopole and non-newtonian forces

J. W. Barrett

Department of Physics, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU, UK

A SOLID spherical object of constant density is a monopole for newtonian gravity. It seems perfectly plausible that monopoles of other shapes ('asymmetric monopoles') exist, and indeed, I have found approximate numerical solutions to this problem. Such asymmetric monopoles are interesting for the detection of deviations from Newton's inverse-square law. Although the newtonian field is monopolar, the field as a result of any deviation will not be. This, in principle, allows one to separate the deviation from the much larger newtonian field, which would normally swamp it on a laboratory scale. A laboratory experiment to detect the proposed 'fifth force' may be feasible.

Figure 1 shows the cross-section through a rotationally symmetric object of constant density that has a hollow interior. The object is created by rotating the figure through the horizontal axis (not shown). The gravitational potential outside the object (referred to as the 'apple' because of its apple-shaped hollow) is $-GM/r$ (where G is the gravitational constant, M is the mass and r is the distance), plus a small error field. The shape is not the only one that may be used to generate an asymmetric monopole, but it is the most suitable from the range that I considered.

In an experiment, one would exploit the fact that the newtonian field is monopolar by rotating the apple about a different axis, for example the vertical axis drawn on Fig. 1, which goes through the centre of mass. The field that results from deviations from Newton's law would then oscillate, and could be observed by using the same apparatus used to detect gravity waves. The use of gravity-wave detectors for this purpose has been suggested or tried in various different ways (see, for example, refs 1, 2 and A. Rüdiger and G. W. Gibbons, personal communication). I assume that the deviation is of 'fifth force' type, as has been suggested by some experiments summarized in refs 3 and 4. The potential of a mass point of mass M has an added term $-\alpha GM/re^{(-r/\lambda)}$ where the dimensionless strength $|\alpha|$ is 0.01–0.05 and the range of the interaction λ is 15–500 m. There is a non-zero dipole field for the fifth force, because the multipole expansion for the fifth force is different from the multipole expansion for newtonian gravity[5].

I assume, as an example, that the apple has a diameter of 1 m and is made from aluminium; its mass is therefore 650 kg.

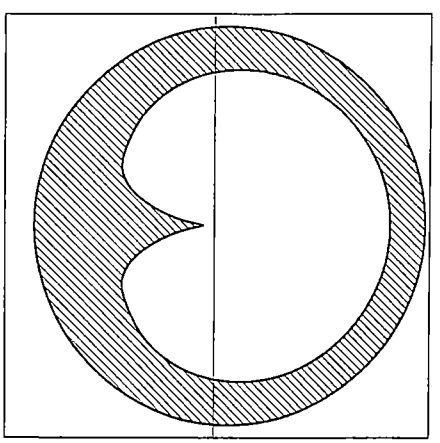

FIG 1 An asymmetric monopole is obtained by rotating the figure about the vertical axis, which passes through the centre of mass

It may be that another metal is more suitable. If a freely suspended test mass is placed at a distance r from the centre of mass of the apple on the horizontal equatorial plane, while the apple is rotated about the vertical axis with frequency f, the test mass will respond to the fifth force with an oscillating radial displacement S of r.m.s. amplitude:

$$\frac{\alpha}{r^3\lambda^2 f^2}\times(9\times10^{-13}\ \mathrm{m^6\,s^{-2}})$$

This formula is a good approximation as long as $r \ll \lambda$. If $r \sim \lambda$, then the formula is somewhat more complicated than this.

The key to doing such an experiment, as far as the detector is concerned, is to achieve good sensitivity at a low frequency, where the isolation from seismic noise is greatest. An advantage is that one can run the experiment for a long time and use a very narrow bandwidth response. With today's laser interferometers; a narrow-bandwidth displacement sensitivity of 10^{-21} m is achievable[6]. If this can be achieved at a frequency $f = 10$ Hz, as may be possible with the new generation of isolating pendula[7,8], the region $\alpha/\lambda^2 > 10^{-6}\ \mathrm{m^{-2}}$ becomes accessible

There are other constraints on the achievable accuracy from the practical aspect of making the source mass. The shapes of the inside and outside contours are given by the formula $a(\theta) = a_0 + a_1P_1(\cos\theta) + a_2P_2(\cos\theta) + \cdots + a_{12}P_{12}(\cos\theta)$, where the Ps are Legendre polynomials and the coefficients a_n are given in Table 1. The newtonian error field, referred to earlier, will depend on the accuracy to which the shape is made. This error field may interfere with the detection of the fifth force. I calculated the error that would result if the shape was formed to within 1 μm, that is, an uncertainty of ±0.5 μm. The error results in small (newtonian) dipole and multipole moments, which will give an oscillating field when the apple is rotated. The relevant $m = 1$ components of the dipole and quadrupole moments are related to the force and couple on the rotating body, and the effects can be measured and controlled. The dipole can be eliminated by shifting the axis of rotation, and the quadrupole contribution is decreased because the harmonic of fundamental frequency vanishes in the equatorial plane. The first moment that cannot be controlled dynamically is the octupole moment. Thus the newtonian error field falls off at least as fast as the octupole moment (r^{-5}) for the displacement measurement S, and one can distinguish a fifth-force dipole from newtonian effects if the results of two measurements at different distances differ by a ratio less than the fifth power of the distance ratio. Table 2 gives the typical errors for a shape formed to within 1 μm, together with the fifth-force signal strength. The effect on the test object is presented in two different ways—the displacement and the strain. These are multiplied by f, λ and α as shown to give invariant quantities. The quantity h is the usual quantity[9] of twice the r.m.s. fractional change in length for a small object, with radial alignment. At this level of accuracy; it seems that one can explore the region $\alpha/\lambda^2 > 10^{-5}\ \mathrm{m^{-2}}$.

TABLE 1 The outer and inner contours

Coefficient	Outer contour	Inner contour
a_0	0 4682370	0 3482169
a_1	0 0347933	0 0969634
a_2	−0 0034762	−0 0450812
a_3	0 0005227	0 0346095
a_4	−0 0000911	−0.0304927
a_5	0 0000171	0.0276200
a_6	−0.0000034	−0 0245809
a_7	0 0000007	0 0209728
a_8	−0 0000001	−0 0168116
a_9	0	0 0123419

a_{12}	0	−0.0013419

TABLE 2 Newtonian error and signal strength

Distance r (m)	Maximum 1-μm shape error: Displacement f^2S ($m\,s^{-2}$)	Strain f^2h (s^{-2})	Fifth force: Displacement $f^2S\lambda^2/\alpha$ ($m^3\,s^{-2}$)	Strain $f^2h\lambda^2/\alpha$ ($m^2\,s^{-2}$)
2	4×10^{-18}	2×10^{-17}	1.1×10^{-13}	3×10^{-13}
4	1.3×10^{-19}	3×10^{-19}	1.4×10^{-14}	2×10^{-14}
8	4×10^{-21}	5×10^{-21}	1.8×10^{-15}	1.3×10^{-15}

The results detailed here show that it may be feasible to use the asymmetric monopole to test the fifth-force hypothesis, although the experiment is obviously not easy, and practical problems remain to be examined in detail. For example, there are small elastic distortions in a rotating body as a result of centrifugal forces. The shape defined by Table 1 is the shape that must be achieved at the final rotation speed. A numerical calculation would give the correct initial shape for a given material. Advantages of the experiment are that the experiment is a null one and one can adjust the shape to find the null, and that only octupole-patterned deformations give rise to error signals as large as in Table 2. Also, the parameters I have chosen (size, distance, tolerance and material) are nominal. There is also the possibility that a refinement of this idea, or an incorporation of the mathematical idea into other experimental techniques (such as torsion balances) may prove effective. I note that the experiment would not depend on any variation of the fifth force with chemical composition, as do many of the recent experiments. □

CO_2 and climate: a missing feedback?

J. F. B. Mitchell, C. A. Senior & W. J. Ingram

Meteorological Office, London Road, Bracknell RG12 2SZ, UK

THE potential of changes in cloud properties to modulate climate perturbations is well known[1,2]. Changes in cloud amount and cloud height[3], cloud radiative properties[4-6] and cloud condensation nuclei[7] (CCN) have all been recognized as possible sources of climate feedbacks. Here we report results of simulations that indicate that the changes of state of cloud water may provide a substantial negative feedback on climate. The feedback is concentrated in mid-latitudes and affects both the magnitude and distribution of the climate change expected from increases in 'greenhouse' gases. Improved measurements and parameterizations of cloud processes are needed to quantify this process.

The model is an 11-level atmospheric general-circulation model on a 5°×7.5° (latitude×longitude) horizontal grid coupled to a 50-m mixed-layer ocean with a prescribed seasonally and geographically varying oceanic heat convergence to represent heat advection by ocean currents[8]. In the standard model[8] cloud cover is a function of relative humidity. A second version of the model was constructed with an explicit cloud-water variable for all but deep convective cloud[9]. A balance is maintained between cloud water content and water vapour, which is altered by dynamical, convective and boundary-layer processes. Cloud water content is depleted by precipitation at a rate dependent on the phase of the cloud water, which is a function of the local temperature of the layer. For water cloud the rate of conversion to precipitation increases as a function of the in-cloud water content and is marginally enhanced in the presence of precipitation from higher layers. The transition from water cloud to ice cloud occurs between −15 °C and 0 °C as a smoothly varying function of temperature. Ice-cloud particles are assumed to start falling as soon as they form, with a fixed fall speed of $1\,m\,s^{-1}$. The rate of precipitation of ice is, on average, an order of magnitude greater than that of water even in the presence of precipitation from the layer above. Cloud radiative properties were prescribed. Note that although the revised cloud scheme is more detailed, it is not necessarily more accurate than the less sophisticated scheme. Our work highlights how different parameterization schemes can affect the sensitivity of the climate to CO_2.

Two simulations, with CO_2 concentrations of 320 and 640 p.p.m., were performed for each version of the model. The results shown here are averaged over five years after the simulations reached equilibrium. On replacing the relative-humidity cloud scheme[8] (henceforth referred to as RH) with the model based on cloud water content[9] (CW), the global annual average surface warming is reduced from 5.2 K to 2.7 K. The largest fractional reduction in the warming occurs in higher latitudes (Fig. 1*a*) where the large decreases in total cloud cover with RH have been replaced by much smaller reductions or slight increases (Fig. 1*b*).

With RH, reductions in cloud cover are found throughout the depth of the mid-latitude troposphere (Fig. 2*a*), as in earlier studies[3]. With CW, the main differences in response occur near the freezing level (Fig. 2*b*) where, in the warmer doubled-CO_2

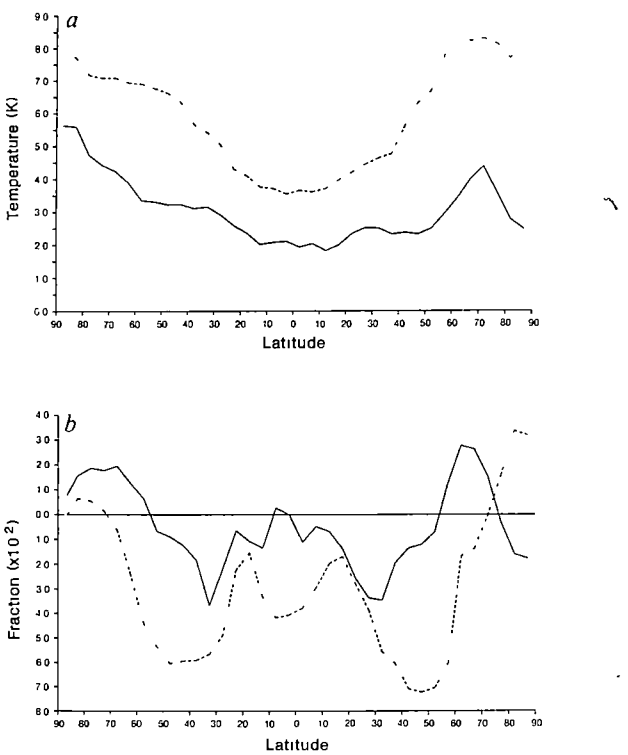

FIG. 1 Zone-averaged equilibrium changes in *a*, surface temperature and *b*, fractional cloud cover on doubling CO_2 (five-year means) Solid line, simulation with CW Dashed line, simulation with RH

simulation, ice cloud which is depleted rapidly by precipitation is replaced by water cloud which is depleted more slowly, so that cloud cover increases. This can be seen more clearly in the height-latitude distribution of the changes in cloud liquid water and cloud ice (Fig. 3). Also shown are the mean 0 °C and −15 °C isotherms in the control simulation. Because of the increases in cloud, the enhanced absorption of solar radiation in mid-latitudes found with RH is greatly reduced when using CW (Fig. 4).

One can define a climate sensitivity parameter λ ($=\Delta Q/\Delta T$) where ΔQ is the change in radiative heating at the tropopause on doubling CO_2 and ΔT is the equilibrium change in surface temperature. Assuming[10] $\Delta Q = 4\ W\ m^{-2}$, λ is increased from 0.77 to 1.48 $W\ m^{-2}\ K^{-1}$ on replacing RH by CW. Thus changes in the phase of cloud water provide a strong negative feedback on climate, cancelling almost all the previous strong positive feedback from cloud in RH[11]. Although our model does not allow for this process in deep convective clouds, these have a small areal coverage and a relatively high liquid-water content, however, suggesting that any radiative feedback from this type of cloud would be small.

The lower-cloud increases in the simulations arise from the assumption that under similar conditions ice is removed more efficiently from cloud than water. In real water clouds, relatively few droplets become large enough to fall out, as the available condensed water is spread over many cloud condensation nuclei (CCN)[12]. Very few CCN act as ice nuclei[13], so in ice clouds the cloud water is spread over fewer, larger particles, all of which have appreciable fall speeds[14]. The microphysics of mixed-phase clouds are complex and not fully understood. Although our model does not explicitly represent them it effectively includes their most important aspect, the continual rapid conversion of water to ice[15]. A more complex representation would certainly change the pattern in Fig. 2 locally, but the vertically integrated response would probably depend primarily on the overall change from pure ice cloud to pure water cloud. Thus our assumptions concerning the relative fall-out of ice and water are at least qualitatively realistic.

As 1 $m\ s^{-1}$ may be a large value for ice fall speed, we have rerun experiment CW using a parameterization of fall speed in terms of ice-water content based on observations[14] (experiment CWH). For typical simulated ice-water contents, this gives fall speeds of 0.2 $m\ s^{-1}$ for high ice cloud and 0.7 $m\ s^{-1}$ for ice cloud near the freezing level. Cloud changes (Fig. 2*c*) are qualitatively similar to Fig. 2*b* and the global warming is 3.2 K, only slightly larger than in CW. The similarity between CW and CWH is to be expected, given that the depletion rate of ice relative to water is large near the freezing level in both experiments.

It has recently been suggested that changes in cloud radiative properties may contribute an important feedback to climate[4,5,16]. In a warmer climate, greater cloud water content would increase cloud albedos (a negative feedback) and emittances (a positive feedback). A further experiment was carried out using the revised version of the model with an additional modification to

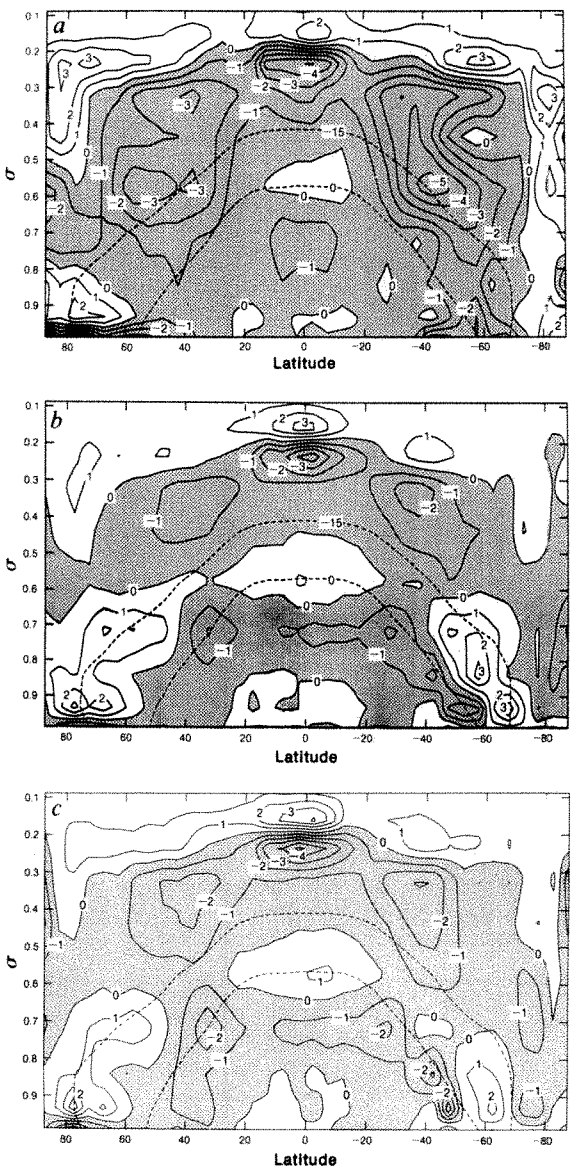

FIG. 2 Height-latitude cross-section of equilibrium changes in cloud amount on doubling CO_2. The height coordinate is σ (pressure/surface pressure). Contours every 4×10^{-7} kg kg^{-1}.

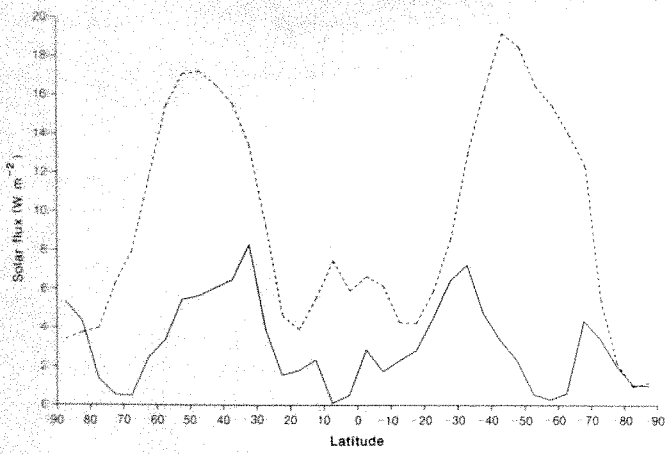

FIG. 4 Zone-averaged equilibrium change in net solar flux at the top of the atmosphere on doubling CO_2 (five-year mean). Solid line, simulation with CW. Dashed line, simulation with RH.

allow the cloud radiative properties to depend on the cloud water content (scheme CWRP). (Given the similarity between CW and CWH, this experiment was carried out with the CW formulation only.) Analytical fits of the short-wave albedo and transmittance as functions of cloud-water path and solar zenith angle were made to a published scheme[17] based on observations and theoretical considerations. The long-wave flux emittance was given by $(1-\exp(-\kappa q))$ where q is the condensed-water path and $\kappa = 0.13\ m^2\ g^{-1}$ for water clouds and $0.065\ m^2\ g^{-1}$ for ice clouds[18].

On doubling the CO_2 concentrations the global annual average equilibrium surface temperature increased by 1.9 K with CWRP compared to 2.7 K with prescribed cloud radiative properties (CW), indicating a further increase in λ to $2.1\ W\ m^{-2}\ K^{-1}$. This negative feedback from changes in cloud radiative properties lies between the very strong negative feedback suggested by one-dimensional calculations[16,19] and the positive feedback found in a previous study with a low-resolution general-circulation model (GCM)[4-6]. We note that all existing numerical studies assume that the number of CCN remains constant under climate change. Changes in CCN are a further possible source of feedback[7,20].

The sensitivity of the climate to doubling the CO_2 concentrations that we have found is substantially smaller than the 4–5 K found in other recent studies[10,21]. A significant part of this reduction in sensitivity is due to the different cloud scheme. If correct this will have two important consequences. First, the equilibrium warming expected from the estimated $2\ W\ m^{-2}$ increase in radiative heating at the tropopause since 1860 (ref. 9) will be smaller. Second, the proportion of the equilibrium reached will be greater, because the thermal response time of the climate system is reduced if climate sensitivity is reduced[22]. Based on calculations using a simple one-dimensional model of the ocean, the expected warming to date, using the climate sensitivity found when employing CW, is 0.6 K. This is close to the observed warming since the beginning of the century (0.5 K; ref. 23). The record of observations shows considerable variability on interannual and interdecadal timescales, however, including a period of cooling during the 1950s and 1960s, so that it is not possible to attribute the 0.5 K rise unambiguously to the effect of increases in trace gases. □

Disequilibrium silicate mineral textures: fractal and non-fractal features

Anthony D. Fowler*, H. Eugene Stanley† & Gérard Daccord‡

* Ottawa-Carleton Geoscience Centre, University of Ottawa, Ottawa, Ontario, Canada K1N 6N5
† Center for Polymer Studies and Department of Physics, Boston University, Boston, Massachusetts 02215, USA
‡ Dowell Schlumberger, Z.I. Molina, BP 90, 42003 St Etienne, Cedex 1, France

IGNEOUS rocks formed from lava flows of the Archaean era (>2,700 million years ago) are often found to contain disequilibrium-textured crystals characterized by spherulitic, branching or dendritic morphologies that occur in layers near the flow surface. Well-known examples are the plagioclase spherulites of basalts and the platy and branching spinnifex-textured olivines and pyroxenes of komatiites[1,2]. Here we present evidence that, over a finite range of length scales, some disequilibrium textures are scale invariant. This observation implies that over this range of length scales their random patterns can be quantitatively characterized by a unique number, the fractal dimension[3]. We also demonstrate that some textures have a crossover from fractal to non-fractal behaviour. It is known that most disequilibrium crystals arise in part from rapid cooling and represent the case where the growth rates of the crystals are large compare to the diffusion rates in the silicate melt[1,2,4]. We therefore formulate a quantitative model for the growth that is based on a variant of diffusion-limited aggregation (DLA)[5].

Figure 1 shows a section of small disequilibrium crystals, at different magnifications. These form close to the quench/glassy margin of some lava flows[6], and their outline remains the same as the microscope objective power is increased. Similar remarks can be made about textures on other length scales, such as the much larger branching pyroxene crystal of Fig. 2*a*.

The concepts and techniques of fractal geometry[3] have proven useful in understanding other random morphologies, in part because a fractal object is characterized quantitatively by a number, the fractal dimension d_f, that relates the increase in mass M of the object to its characteristic length scale L, $M \approx L^{d_f}$ (ref. 7).

To determine d_f we digitized photographs of the textures using a video camera with a grid of 65,536 pixels. First we randomly chose any pixel belonging to the digitized texture. About this 'local origin' we constructed a sequence of concentric shells of

radius r. For each shell, we formed the correlation function $\mathscr{C}(r)$ by dividing the number of pixels belonging to the texture by the total number of pixels in that shell. To obtain good statistics we repeated the calculation using all texture pixels as local origins.

The correlation function $\mathscr{C}(r)$ gives the probability that a pixel separated from the local origin by a distance r is part of the pattern. We expect this function to scale in the same way as the density of pixels in a two-dimensional fractal object[7].

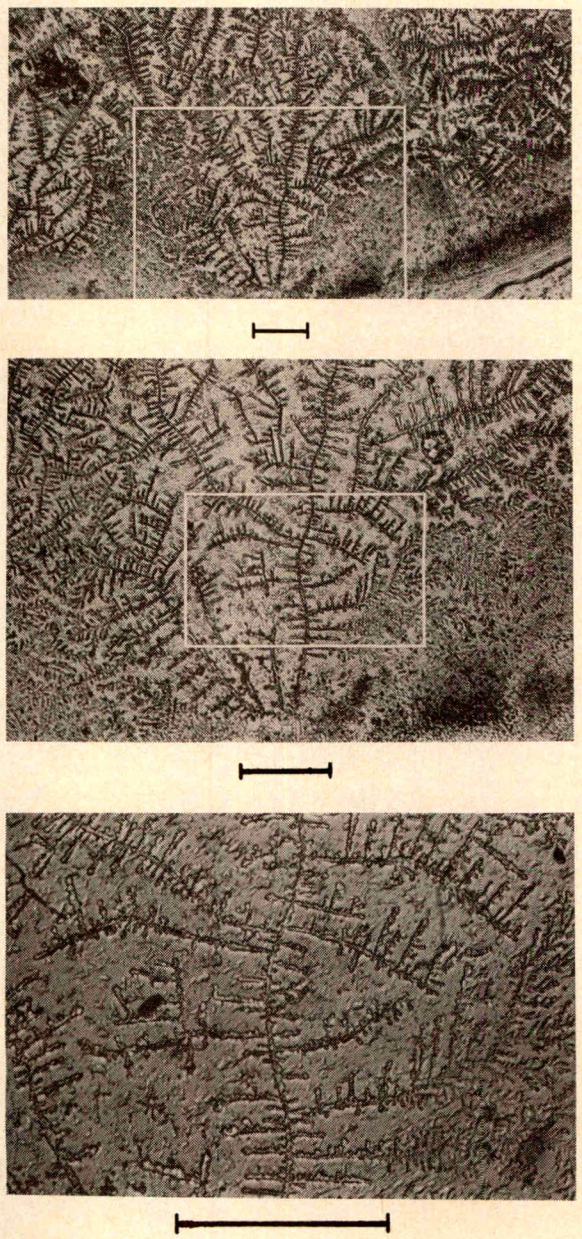

FIG. 1 Photomicrographs taken at increasing magnifications of the same field, of branching crystals (interpreted to be olivine) sampled from beneath the quenched pillow margin of an Archaean metabasalt flow. The scale bars represent a length of 0.1 mm. The enclosed areas indicate the field of view of the subsequent image. The branching pattern is independent of magnification; this scale invariance is characteristic of fractal objects. The images were taken using Nomarski interference microscopy of acid-etched samples[15]. Pillows may form during subaqueous eruption when lava in contact with water quickly quenches to a glass. The glass remains plastic and deforms under pressure of the flow into a bulbous shape (pillow) in a manner analogous to blown glass, except that the interior is lava filled. The pillows often contain a spectrum of mineral growth morphologies from the glassy margin to the slowly cooled pillow centre (~0.5 m).

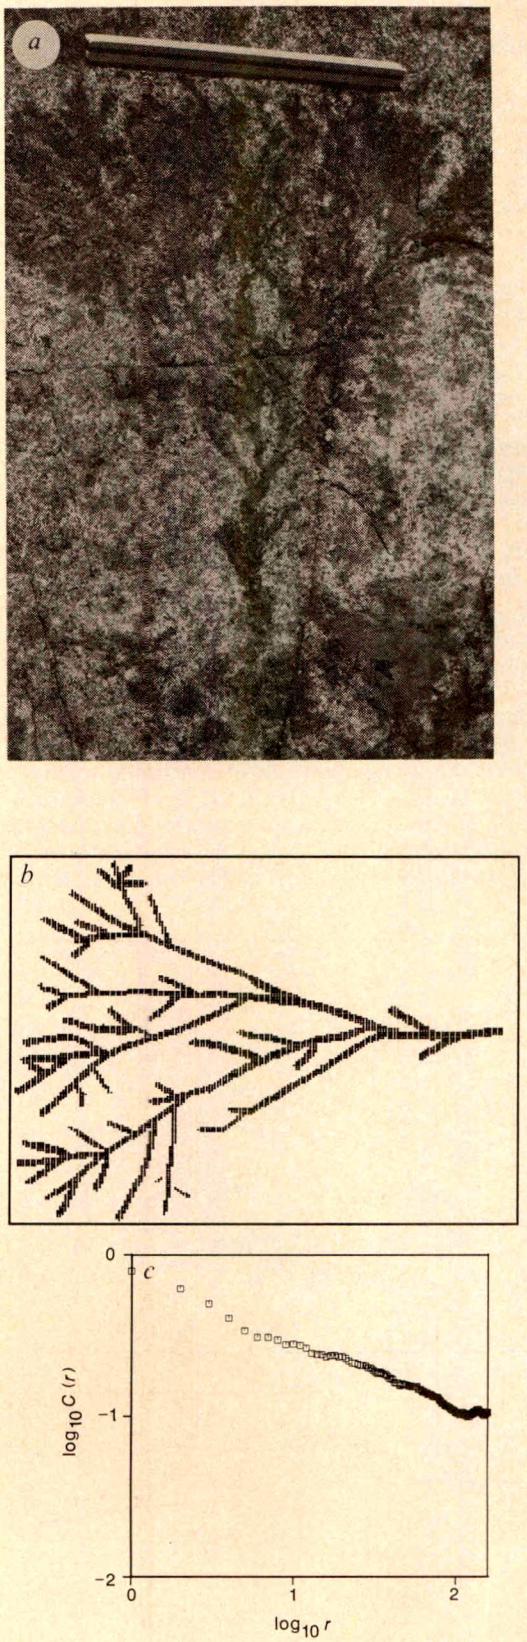

FIG. 2 *a*, Photograph of a large (scale = 32 cm) branching pyroxene from a gabbro sill in Munro Township of the Archaean Abitibi Subprovince, Ontario. These branching crystals are most evident on weathered surfaces and are exposed over several hundred metres of the sill in a haphazard manner. Elsewhere, such as at the location of the photo, their long axes are normal to cooling contacts. The crystal is clearly scale invariant and fractal in form. *b*, is the digitized form and *c*, shows that $d_f = 1.60 \pm 0.10$.

That is, the number of pixels that form part of the object is not proportional to the square of r but to the power d_f,

$$\mathscr{C}(r) \approx r^{d_f-2} \quad (1)$$

Thus the slope of a double logarithmic plot of $\mathscr{C}(r)$ against r gives a quantitative value of d_f.

Figure 3*a* shows a digitized version of the olivine of Fig. 1. Figure 3*b* is a double logarithmic plot of $\mathscr{C}(r)$ against r, and shows that for r less than a crossover value r_c of about 70 pixels, the data fall on a line of slope -0.20, corresponding to $d_f = 1.80 \pm 0.05$. For $r > r_c$, $\mathscr{C}(r)$ has a constant 'saturation' value $\mathscr{C}_{sat}$; hence over this range the object is non-fractal. We can check the numerical value of $\mathscr{C}_{sat}$ by calculating the mean density of the pattern; we find 6,682 black pixels in a total area of $222 \times 201 \approx 44{,}000$. Hence we expect $\log \mathscr{C}_{sat} \approx \log(0.15) \approx -0.82$ indicating that the initial concentration of olivine 'components' in the liquid was on the order of 15% in accordance with measured estimates of the sum of the contents of FeO and MgO of the rock[6].

We analysed at least a dozen additional crystals and consistently found evidence for their fractal nature below a crossover radius r_c. For example, the pyroxene (Fig. 2) has $d_f = 1.60 \pm 0.10$. The larger statistical uncertainty is due to the fact that outcrop weathering has somewhat obscured the outline of the crystal.

Experimental studies have clearly documented the conditions responsible for the growth of disequilibrium silicate crystals, but an understanding of the physical mechanisms remains obscure. We note that the fractal dimensions we find are similar to those found for DLA. The DLA algorithm starts with a seed particle and releases a random walker from the periphery of a circle enclosing the seed. When the random walker touches the seed, it sticks and a second walker is released. This process is iterated until a large aggregate is formed. The random walkers in DLA correspond to structural units in the silicate melt which undergo Brownian motion and upon collision attach to a central nucleus without rearrangement. The model is thus somewhat analogous to crystal growth in a magma under conditions of high supercooling. Protuberances preferentially grow because the probability is small that a molecule in a highly supercooled liquid will travel without collision into the 'fjords' between the branches of the crystals.

These disequilibrium crystals share other characteristics with DLA in addition to having a similar value of the fractal dimension. For example, they display a ramified (branched) structure, starting from a unique seed. Moreover, the branches do not form any 'closed loops'. A main difference between the DLA model and actual physical agglomeration processes is that the concentration of particles tends to zero in the DLA model. In any physical system, however, there is a finite concentration of molecules. This leads to the possibility that growth can occur in several different places at the same time. The effect[8] of deviation from this limiting condition of zero concentration on the structure of the final patterns is the crossover from fractal behaviour at small length scales to non-fractal (that is, constant density) behaviour at larger length scales. The characteristic length at which this crossover occurs depends on the concentration of particles and seeds.

Figure 4 shows the results of a 'finite-concentration' simulation, with the added feature that anisotropy has been introduced. Several seed particles are introduced and a non-zero concentration of walkers is distributed at random. At each time step, each walker attempts to move to one of its four neighbouring sites (chosen at random). If the neighbouring site is empty, the move is allowed, otherwise the move is prohibited. When a walker steps on a perimeter site of any cluster, it sticks irreversibly.

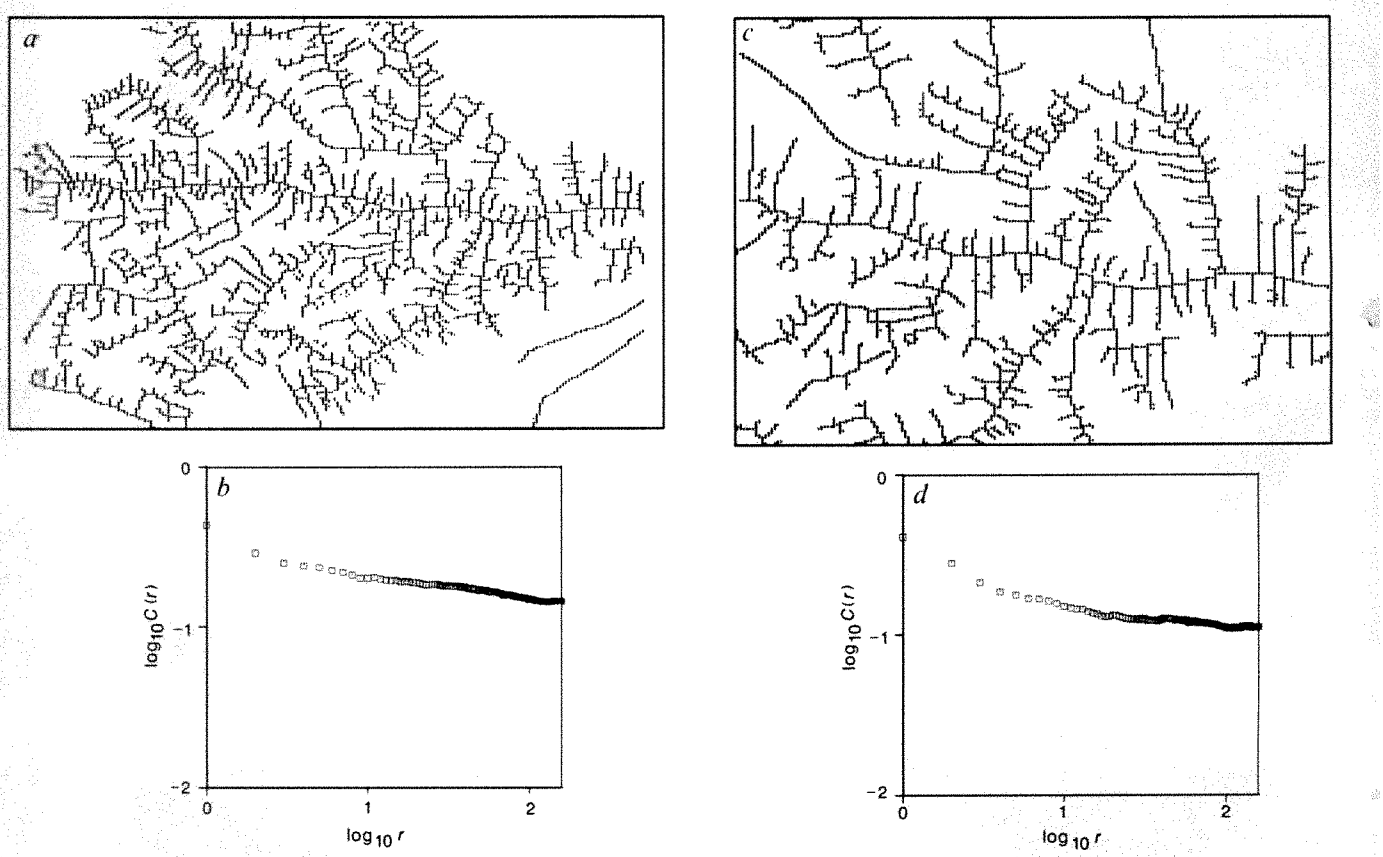

FIG. 3 *a*, Digitized representation of the central area of Fig. 1*a*. *b*, The graph of the correlation function as a function of length is characteristic of fractal forms and yelds $d_f = 1.80 \pm 0.05$. *c* and *d*, The digitized forms of the central area of Fig. 1*b* and the graph of correlation function as a function of length respectively, $d_f = 1.72 \pm 0.07$. Note that the fractal dimensions d_f of the two images are almost identical under change of scale.

Anisotropy is present in disequilibrium-crystal growth. The anisotropy is assumed to start when the fastest growing face of the crystal nucleus is aligned with the thermal or compositional gradient. Once initiated, the preferred direction is conserved as the crystals grow out from the depleted area in the direction of highest concentration, normal to the cooling contact. We have incorporated anisotropy in our model by introducing a local noise reduction. In conventional global noise reduction, a particle sticks after visiting a perimeter site s times (see, for example, ref. 9). In contrast, for local noise reduction, the parameter s has a lower value for perimeter sites co-linear with cluster sites; for the simulation of Fig. 4, we chose $s=1$ for perimeter sites aligned with the previous direction of growth and $s=2$ for the remaining perimeter sites.

The similarity of the olivine photographs (Fig. 1) and the simulation (Fig. 4) is rather striking, both qualitatively and quantitatively (they have roughly the same value of d_f, followed at a larger distance by a crossover to constant mass density). At small radii the short distance between tips of the mineral relative to the diffusion length of the molecules prevents in-filling, whereas at larger radii in the presence of a finite number of molecules the diffusion length is short with respect to tip distance so in-filling growth becomes more probable.

Although the stochastic model presented, DLA, provides us with a physical mechanism of growth, it yields no quantitative information about the actual mineral growth. A kinetic model that is a variant of DLA may be used, however, to calculate parameters associated with the growth of the olivine at the crossover. We use the Smoluchowski formulation, a theory of anomalous reaction kinetics that accounts for diffusion-limited growth. We base our analysis on the finding[8] that this crossover is entirely due to the finite concentration of particles. When the crossover occurs, the average displacement of a particle during a period of time δt equal to the mean time between two particles sticking on the cluster is of the order of the size of the cluster,

$$\sqrt{D\,\delta t} = r_c \tag{2}$$

To calculate δt we assume a given diffusivity D for the particles and thereby obtain an estimate of the particle concentration and other physical parameters.

We assume the flux of particles sticking on the cluster is the same as if the cluster were a filled sphere of size R; this assumption has been verified to hold for DLA[10], provided R is equal to an effective radius of the DLA cluster. This effective radius is smaller than the DLA actual outer radius but of the same order of magnitude. Therefore we use the expression of the flux of incoming particles toward a spherical sink[11,12]

$$\phi = 4\pi DRC\left(1+\frac{R}{\sqrt{\pi Dt}}\right) \tag{3}$$

where ϕ is the flux (number of particles per unit of time), R the cluster radius (effective radius of the DLA cluster), C the particle concentration far from the cluster and t the time since the beginning of the growth.

For DLA simulations the mean time between growth events δt corresponds to an increase in branch length equal to the particle size. The mean branch width for DLA is almost equal to the particle size[13]. Although the branch width W of real physical objects such as the minerals discussed here remains essentially constant, W^3 is much larger than the size of an individual molecule. Hence the corresponding mean time δt required to increase the branch length by W is simply $1/\phi$ multiplied by the number of molecules A, in a cube of volume W^3 of the mineral. Thus

$$\delta t = \frac{A}{\phi} \tag{4a}$$

and

$$A = W^3(\rho/M)N_A \tag{4b}$$

where ρ and M are the mineral density and relative molecular mass respectively, and N_A is Avogadro's number. For long times (for example, the time t required to reach $R=r_c$), equation (3) reduces to $\phi = 4\pi Dr_cC$ and from equation (4a)

$$\delta t \simeq \frac{A}{4\pi Dr_cC} \tag{5}$$

The concentration of species at the crossover may be calculated because $\delta t = r_c^2/D$ from equation (2). Thus equation (5) becomes

$$C \simeq \frac{A}{4\pi r_c^3} \tag{6}$$

From Fig. 3b we see that $r_c = 67$ pixels, which corresponds to 0.022 cm in Fig. 3a. Because a branch width is one pixel, $W = r_c/67 = 3.3\times10^{-4}$ cm. Using equation (4b), we obtain $A = 4.25\times10^{11}$ molecules. Hence from equation (6), $C = 3\times10^{15}$ molecules cm^{-3}. Using $D = 5\times10^{-7}$ cm^2 sec^{-1}, we calculate from equation (5) that the time δt of growth at the crossover is 970 s, yielding an instantaneous growth rate of 3.4×10^{-7} cm s^{-1}, similar to that reported[14] for skeletal olivine growth. Because the growth rate of DLA slows with growth, our value is a lower bound.

These results should be considered only as order of magnitude estimates because we have used very rough assumptions, the most critical of which is the use of equation (3). In the absence of any quantitative theory for DLA, however, we could not find an alternative approach. □

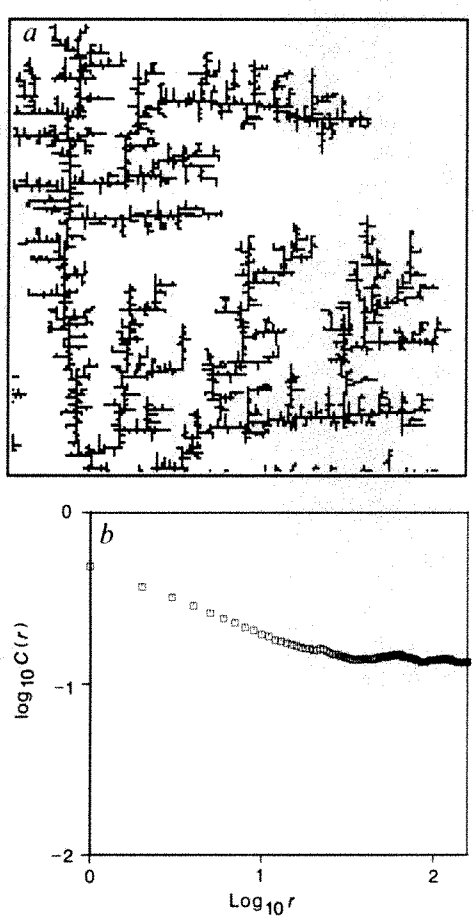

FIG. 4 *a*, Pattern simulated using the algorithm of ref. 8 modified to include local noise reduction ($s=2$ here). Of a total of 32,400 available pixels, 4,512 were selected as mobile particles. Only the central part of the simulation is illustrated because of boundary effects. *b*, The plot of the density correlation function, showing that in the fractal region $d_f=1.73$. The crossover to non-fractal behaviour occurs at $r\approx30$.

Carbon isotopes in soils and palaeosols as ecology and palaeoecology indicators

T. E. Cerling, J. Quade, Y. Wang & J. R. Bowman

Department of Geology and Geophysics, University of Utah, Salt Lake City, Utah 84112, USA

THERE are few quantitative techniques in use today for palaeoecological reconstruction in terrestrial depositional systems. One approach to such reconstructions is to estimate the proportion of C_3 to C_4 plants once present at a site using carbon isotopes from palaeosol carbonates[1–3]. Until now, this has been hampered by an inadequate understanding of the relationship between the carbon isotopic composition of modern soil carbonate and coexisting organic matter. Here we have found that the two systematically differ by 14–16‰ in undisturbed modern soils. This difference is compatible with isotopic equilibrium between gaseous CO_2, and aqueous and solid carbonate species in a soil system controlled by diffusive mass transfer of soil CO_2 derived from irreversible oxidation of soil organic matter. Organic matter and pedogenic carbonate from palaeosols of Pleistocene to late Miocene age in Pakistan also differ by 14–16‰. This indicates that diagenesis has not altered the original isotopic composition of either phase, thus confirming their use in palaeoecological reconstruction.

Stable carbon isotopes in pedogenic carbonate[1–4] and soil organic matter[5,6] can be used as palaeoecological indicators. A critical assumption, however, in the use of pedogenic carbonate is that of isotopic equilibrium between the carbon species—soil CO_2, dissolved carbonate species, and solid carbonate—in the soil system buffered by an effectively infinite soil CO_2 reservoir. Other studies in recent years have invoked processes such as 'Rayleigh' distillation[7,8], kinetic fractionation[8], and partial exchange or inheritance[8,9] to describe carbon isotope systematics in soils. The principal drawback of the latter models is that little isotope data on co-genetic organic carbon and soil carbonate was collected. Instead, the isotopic composition of the organic matter was usually assumed[7–9]. Where measured, the results were considered unreliable because of the vegetation changes resulting from cultivation[8]. Many of the studied soils have complex vegetational histories attributable to either the effects of cultivation and extensive grazing[7–9] or, in the case of calcretes[7], to long periods of development in the presence of pre-Holocene vegetation. These complexities make interpretation of the soil isotope system exceedingly difficult.

Our approach is to study ten soils in North America with simple pedogenic histories (Table 1). All the soils are latest Pleistocene or, in most cases, entirely Holocene in age. In all but one case, vegetation cover can be assumed to have been constant and similar to that of today. The six mid-western soils are located on national prairie preserves where the vegetation shows little or no post-settlement impact. The Nevada soils come from remote mountain settings that are unsuitable for grazing, in which vegetation remains entirely native. Vegetation at the New York site, though disturbed, must always have been 100% C_3 in character given the forested nature of the region.

The isotopic composition of plants using the C_3 and C_4 photosynthetic pathways have $\delta^{13}C$ values averaging ~ -27 and -13‰, respectively[10]. We have examined ten soils the biomasses of which span the range from nearly 100% C_3 to 100% C_4 and have analysed coexisting bulk-soil organic matter and pedogenic carbonate in each. The soil carbonates were present as nodules and as pendants on pebble undersides. We confined our studies to areas where the rainfall exceeds 35 cm yr^{-1} because modelling of soils shows that pedogenic carbonate from soils with very low respiration rates, such as in deserts, can be isotopically enriched because of diffusional mixing with the atmosphere[1,11]. We sampled carbonates at depths >30 cm because the near-surface carbonate could be affected by diffusional mixing with atmospheric CO_2, irrespective of the soil respiration rate. Nearly all the soils studied contained carbonate in the parent alluvium, loess or till.

The diffusion coefficients for $^{12}CO_2$ and $^{13}CO_2$ differ, producing a 4.4‰ enrichment in the plant-derived component of soil CO_2 compared with respired CO_2 (refs 1, 11, 12). At equilibrium, the isotopic equilibrium factor $10^3 \ln \alpha_{CO_2\text{-calcite}}$ is -9.8 to -12.4 for the temperature range 25–0 °C (ref. 13). Pedogenic carbonate precipitated in equilibrium with soil CO_2 should, therefore, be $\sim$14‰ (25 °C)–17‰ (0 °C) enriched relative to respired CO_2. At low soil respiration rates, carbonates precipitated in equilibrium with soil CO_2 would have an even greater enrichment as a result of the atmospheric effects mentioned above.

The isotopic composition of pedogenic carbonate from a single soil in the Konza Prairie of Kansas is constant in the soil from depths of 40 to 103 cm, and it is 14.5‰ more positive than the co-existing organic material in the soil (Fig. 1). This difference supports the model of a diffusion-controlled soil CO_2–$CaCO_3$ system in isotopic equilibrium. The patterns displayed by this soil and those described below are not consistent with kinetic or Rayleigh distillation processes resulting in isotopic disequilibrium between soil CO_2 and precipitated carbonate. Similarly, modern soil organic matter and coexisting pedogenic carbonate from nine other North American soils differ by $\sim$14–16‰ (Fig. 2), as predicted for high-respiration-rate soils. All soils we studied, including palaeosols from Pakistan, show strong leaching and contain well developed organic horizons, thus indicating high respiration rates[14,15]. In low-respiration-rate soils, such as in deserts, diffusional mixing of atmospheric CO_2 and plant-derived CO_2 can produce up to 2‰ enrichment in the $\delta^{13}C$ of soil carbonate at 50-cm depth[11]. No systematic trend in

Fig. 2 would be expected for soils in which the vegetation has been altered by agricultural or pastoral practices or, in the case of old surface soils, by major climatic change. The isotopic compositions of all the soils studied are compatible with a diffusion-controlled system in which all oxidized carbon species are in isotopic equilibrium. Therefore, the isotopic composition of soil organic matter or pedogenic carbonate in high-respiration-rate soils is a direct indicator of the fraction of the biomass using the C_3 or C_4 photosynthetic pathways.

Obtaining palaeoecological information from palaeosol carbonates and organic matter requires that the sampled palaeosols bear the imprint of time spans during which vegetation remained undisturbed by humans or by major climate change, as in the case of the modern soils we selected for study. Clearly, buried pre-Holocene palaeosols of any type should not have experienced anthropogenic modification. We estimate that the length of pedogenesis for Pliocene and Pleistocene soils in Pakistan to have been <10,000–15,000 yr, and probably much less in most cases. Thus, the carbonate build-ups in these palaeosols should not be, in most instances, polygenetic. Palaeosol humus probably represents organic matter from the last few hundred years before burial, given the short residence times typical for humus in most modern soils[15].

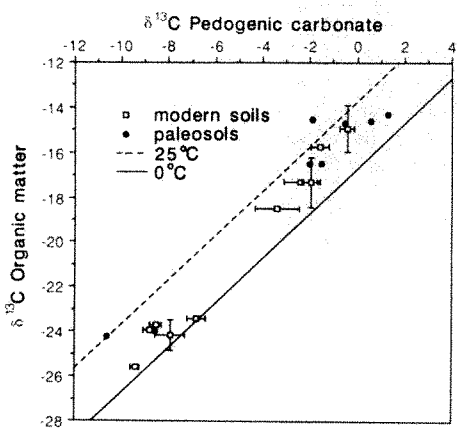

FIG. 2 The isotopic composition, relative to the PDB standard, of co-existing organic matter and pedogenic carbonate from ten modern North American soils, and from eight late Miocene-to-Pleistocene palaeosols in Pakistan. Solid lines represent isotope values for pedogenic carbonates in isotopic equilibrium with soil CO_2 derived from irreversible oxidation of soil organic matter in a diffusion-controlled soil system[1,11] at 0 and 25 °C.

Figure 2 also shows the isotopic composition of co-existing palaeosol organic matter and pedogenic carbonates from palaeosols in the Siwalik sequence of Pakistan. The concordance with the modern trend indicates that the pedogenic carbonates in the palaeosols have not been isotopically altered during diagenesis, notwithstanding several kilometres of burial. The isotope results from two Pakistani palaeosols indicate the highest soil temperatures of any soil or palaeosol studied. Mean annual temperatures and maximum soil temperatures (at 50-cm depth) for the Potwar Plateau of Pakistan are ~24 and 33 °C, respectively, much higher than for any North American site. Although this is interesting, we feel that use of co-existing carbonate-organic matter in palaeosols as a palaeotemperature indicator is premature, given the small sample size. Further evidence against diagenetic alteration is that modern soils and Miocene-to-Pleistocene palaeosol carbonates both range from −11 to +2‰, whereas coexisting organic matter for both range from ~−25 to −13‰.

Carbon isotope analysis of coexisting organic matter and pedogenic carbonate constitutes a simple test of the state of preservation of the original palaeoecological signal in soils. □

Crystal chemistry of phase B and an anhydrous analogue: implications for water storage in the upper mantle

L. W. Finger*, J. Ko†, R. M. Hazen*, T. Gasparik†, R. J. Hemley*, C. T. Prewitt* & D. J. Weidner†

WATER locked in mineral phases within the Earth's mantle may be as significant for the development of life as water now found at the planet's surface. The Earth's original hydrosphere probably would not have survived a collision with a Mars-sized object, such as may have formed the Moon[1]. The water now on the surface could have been replenished by further impacts of smaller planetesimals; however, at least a portion could have been stored in minerals deep in the mantle being released gradually through volcanic eruptions. This mechanism requires a stable high-pressure phase able to store water under mantle conditions. Of the several hydrous phases studied in the past, the material known as phase B has the highest density and is the only known hydrous form stable at pressures corresponding to depths of 400–500 km (refs 2, 3). Although phase B has been known for over twenty years, its crystal structure and crystal chemistry have remained an unsolved problem. Here we describe the crystal structures of phase B ($Mg_{12}Si_4O_{19}(OH)_2$) and a chemically and structurally similar anhydrous form, AnhB ($Mg_{14}Si_5O_{24}$). These structures contain silicon in both fourfold and sixfold coordination; the silicon octahedra share all twelve edges with magnesium octahedra in a unique thirteen-cation cluster. Description of the structures of phases AnhB and B requires 18 and 40 atoms, respectively, demonstrating that high-pressure phases can have very complicated crystal structures. The multitude of octahedral sites in these phases could lead to rather complicated fractionation behaviour during solid–solid or solid–liquid transitions in the presence of other octahedrally coordinated ions such as Al, Fe, Ti and Mn.

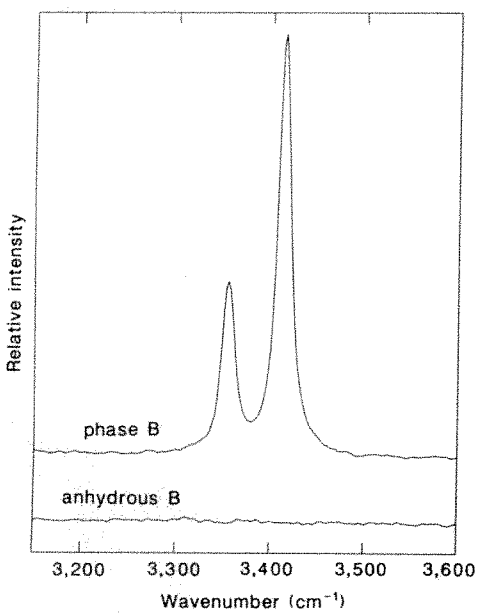

FIG. 1 Raman spectra of phase B (top curve) and anhydrous phase B (bottom curve) measured with 457.9-nm laser excitation (~25 mW) and 5-cm^{-1} resolution. The peaks in the phase B spectrum, which arise from OH-stretching vibrations, appear at 3,414 and 3,356 cm^{-1}, frequencies similar to those found[4] in the infrared absorption spectrum.

The stability of high-pressure hydrous phases has been known since the report[2] of preliminary data for what were named phases A, B and C. Phase B, which formed from gels with Mg/Si = 3 at pressures >11 GPa, had the highest density of the new forms and seemed to be an interesting possibility for the mantle, whether hydrous or not. The determination[3–5] of the unit cell, space group and infrared spectra of synthesized crystals of phase B confirmed the presence of hydroxyl groups; the structure, however, was not determined. The hydrous phase B was reported[6,7] to be the second liquidus phase for natural lherzolite and synthetic compositions that were heated at a pressure of 20 GPa. No water was added to the capsules in these experiments and the hydrous phase seemed to persist at very high temperatures even though water usually enters the melt at relatively low temperature. Electron-microprobe results suggest[8] that this high-temperature phase is actually anhydrous.

Single crystals of phase B were synthesized in a split-sphere anvil apparatus (USSA-2000) starting from a gel with Mg/Si = 3. The charge was heated to 1,200 °C at 12 GPa and cycled between 1,200 and 1,300 °C, a procedure that produced the largest grain size. Crystals selected from the run products have a monoclinic cell (see Table 1) similar to that reported in ref. 5. Some crystals demonstrate twinning, which we believe to be the result of a twofold operator parallel to [001], but, most did not. In addition, high-resolution transmission-electron-microscope photographs did not indicate the presence of stacking faults. The unit-cell geometry and space group are highly suggestive of a structure with some layers similar to that of MgO and a six-layer stacking sequence. In such a structure, the oxygen substructure would have cubic closest-packing arrangement, a situation confirmed by a Patterson synthesis. Because of this pseudosymmetry, a solution was not obtained by the standard direct methods.

Single crystals of the new phase, AnhB, were grown from a starting material consisting of synthetic forsterite that had been dried at 1,000 °C in argon immediately before the experiment; run conditions were 2,380 °C and 16.5 GPa for 2 h. The new phase formed large single crystals at the centre of the capsule, with quenched crystals in the hot end and β-Mg_2SiO_4 in the colder portion of the charge. Phase AnhB was formed by incongruent melting of β-Mg_2SiO_4 to AnhB plus melt, which segregated during the experiment. Electron-microprobe analysis gave an atomic Mg/Si ratio of 2.81 (9 analyses) and a total close to 100%. The lattice (see Table 1) also indicates a six-layer stacking sequence. Although this structure has pseudosymmetry, the solution was obtained by routine direct methods[9] and difference electron-density calculations; the phase is isostructural[10] with $Mg_{14}Ge_5O_{24}$. We have revised the choice of orthorhombic axes, however, to maintain the similarities between phases B and AnhB. To test for substitution of $Mg+H_2$ for Si, valence-bond sums[11] were calculated. All oxygen ions were fully bonded; furthermore, the Raman spectra (Fig. 1) showed none of the features associated with the presence of OH groups. An a–c projection of the structure is shown in Fig. 2. Not only is this the phase identified in ref. 8 but it is probably the high-temperature form identified as phase B in refs 6, 7. In addition, phase B has been found[12] to break down at high pressure at ~1,000 °C; above 22 GPa, the quenched sample consisted of one or more unknown phases. Phase AnhB, with some Fe substitution for Mg, would explain two of the three strongest X-ray lines found in that study. Another, as yet unidentified, phase is required to account for the third diffraction line. It is probable, however, that this phase is produced in a reaction that yields free water as a product.

Using the structure model for AnhB we obtained the solution of the hydrous form. The Raman spectrum (Fig. 1) indicates two distinct OH groups, which is consistent with the calculated

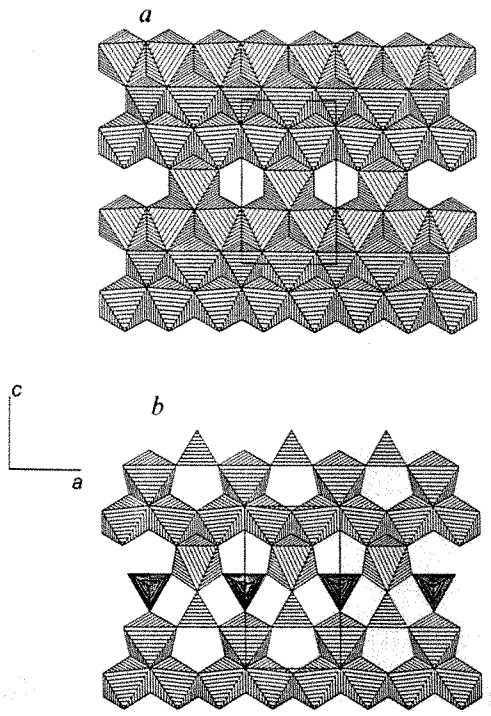

FIG. 2 Polyhedral[20] projection of the structure of $^{VI}Mg_{14}{}^{VI}Si_1{}^{IV}Si_4O_{24}$ (AnhB) viewed parallel to (010). (Roman-numeral superscripts indicate the coordination). Structure consists of two types of layers repeated by symmetry. Magnesium is in six-fold coordination as in olivine or spinel; however, silicon is in mixed coordination. *a*, Defect (Mg, Si)O layer, with $-0.12 \leq y \leq 0.12$, similar to that of spinel[21], but with fewer vacancies and with a smaller Si octahedron at the origin. There are two layers of this type per unit cell. *b*, Layer with $-0.30 \leq y \leq -0.07$ containing Mg octahedra and Si tetrahedra. There are four layers of this type per unit cell. The Si octahedron in *a* is capped by a cluster of Mg octahedra; thus all 12 edges of the Si octahedron are shared with Mg octahedra. The Si tetrahedra are placed directly over the hole in the first layer; thus, octahedra and tetrahedra share corners as in spinel rather than olivine; this layer is identical, however, to *b*–*c* layers of the olivine structure.

TABLE 1 Equivalent isotropic temperature factors and mean bond distances for cations of phases AnhB and B

Diffraction experiments with Rigaku AFC-5 diffractometer, rotating-anode generator, Mo $K\alpha_1$ radiation, graphite monochromator, $\lambda = 0.7093$ Å, ω step scans to $2\theta = 60°$, ambient pressure and temperature. Phase AnhB: $a = 5.868(1)$ Å; $b = 14.178(1)$ Å; $c = 10.048(1)$ Å; $V_{cell} = 835.9$ Å^3. Space group *Pmcb*; $Z = 2$; relative molecular mass = 864.8; $\rho_{calc} = 3.435$ g cm^{-3}; linear absorption coefficient $\mu_l = 10.8$ cm^{-1}; range of transmission factors = 0.81–0.92; two octants measured; internal agreement 2.5%. Residuals $R = \Sigma||F_o| - |F_c||/\Sigma|F_o| = 0.040$, $R_w = \Sigma\sigma_F^{-2}(F_o - F_c)^2/\Sigma\sigma_F^{-2}F_o^2 = 0.025$ for all 1,337 independent data where F_o is the observed structure factor and F_c the calculated structure factor, $R = 0.029$, $R_w = 0.024$ for 1,132 data with $F_o > 2\sigma_F$; goodness of fit = 0.9 for anisotropic temperature factors. Phase B: $a = 10.588(2)$ Å; $b = 14.097(1)$ Å; $c = 10.073(1)$ Å; $\beta = 104.10(3)°$; $V_{cell} = 1{,}458.4(3)$ Å^3. Space group $P2_1/c$; $Z = 4$; relative molecular mass = 742.1; $\rho_{calc} = 3.368$ g cm^{-3}; $\mu_l = 10.3$ cm^{-1}; Range of transmission factors = 0.87–0.94; hemisphere of reciprocal space measured; internal agreement 3.5%. $R = \Sigma||F_o| - |F_c||/\Sigma|F_o| = 0.080$, $R_w = \Sigma\sigma_F^{-2}(F_o - F_c)^2/\Sigma\sigma_F^{-2}F_o^2 = 0.041$ for all 4,263 independent data; $R = 0.039$, $R_w = 0.056$ for 3,254 data with $F_o > 2\sigma_F$; goodness of fit = 1.0 for anisotropic temperature factors.

* Numbers in parentheses are the estimated standard deviations in the last decimal places.

valence sums[11]. These values are 1.2 and 1.3, respectively, compared to a value of 2.0 for a fully bonded ion. A nearby oxygen had a value of 1.6 indicating an asymmetric hydrogen bond. Trial positions were generated from these calculations and the parameters of all atoms were refined, using anisotropic thermal models for all non-hydrogen atoms. Figure 3 is an *a*–*c* projection of the structure. The hydrogen atoms lie 0.8–0.9 Å from the oxygen associated with a silicon tetrahedron.

The high density of these structures arises, in part, from total edge sharing between the silicon octahedron and the surrounding magnesium octahedra, which forms a thirteen-cation cluster. Unlike the lower-pressure forms olivine, clinohumite, humite, chondrodite and norbergite[13], and the hydrous high-pressure form, phase A[14], the new structures do not contain shared edges between tetrahedra and octahedra. In addition, only phases B and AnhB have silicon in octahedral coordination.

Other high-pressure forms of magnesium silicate may exist. The germanate form of AnhB has been described[15] as a member of a homologous series containing variable ratios of olivine and defect rock-salt layers (in AnhB this ratio is 2:1). $Mg_{10}Ge_3O_{16}$, a stoichiometry that might occur in the silicate system has also been reported[16]. As shown in Fig. 3, phase B can be described as a 2:1 mixture of humite and defect rock salt. It is probable that the 1:1 form, which would have a hexagonal close-packed oxygen array with composition $Mg_{17}Si_5O_{26}(OH)_2$, also exists. Other series based on clinohumite, chondrodite or norbergite layers mixed with the appropriate octahedral layers can be imagined. In addition as phase B can be related to AnhB by a 'shearing' parallel to the *c* axis, one can propose other forms involving different slab widths or 'shear' offsets leading to further structures or complex intergrowths such as those found in the biopyriboles[17].

This study illustrates the utility of a large-volume high-pressure apparatus in growing single crystals of high-pressure phases that are suitable for crystal structure determination. This is important because the solution of these complicated structures would not be possible with powder X-ray diffraction methods. We note that very complex crystal structures can exist at high pressure in contradiction to the standard assumptions. For example, it has been proposed[22] that the lower mantle is composed predominately of simple orthorhombic perovskites over the entire *P*–*T* range. Although there is no evidence to refute this claim, we emphasize that it has not yet been confirmed by *in situ* simultaneous high-pressure and high-temperature measurements.

This study also has implications regarding the storage and release of water in the upper mantle. Although these phases are more magnesian than any possible mantle model, mixture with stishovite would permit any desired Mg:Si value, with a high density. The assemblage B + stishovite with Mg/Si = 1.5 has 1.8% H_2O and an atmospheric-pressure density of 3.554, which is 9% denser than A + spinel + clinoenstatite of the same composition and 8% denser than clinohumite + stishovite[18]. Phase B is stable to 22 GPa at 1,000 °C (ref. 12), but transforms to AnhB at higher temperatures according to our interpretation of the data in ref. 6. This reaction, which might be B + spinel →

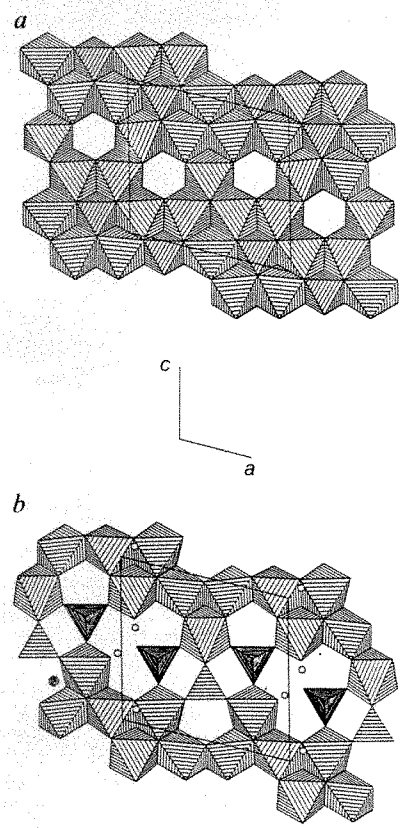

FIG. 3 Polyhedral projection of the structure of $^{VI}Mg_{12}{}^{VI}Si_1{}^{IV}Si_3O_{19}(OH)_2$ (Phase B) viewed parallel to (010). (Roman-numeral superscripts indicate coordination.) This structure also has a two-layer form. *a*, The defect (Mg, Si)O layer, with $-0.12 \leq y \leq 0.12$, has a central vertical section identical to that of Fig. 2*a*; however, there is a 'sheared' relationship between adjacent strips in the hydrous form. Note that the silicon octahedron is no longer located at the origin. *b*, Layer with $-0.30 \leq y \leq -0.07$ containing Mg octahedra, Si tetrahedra, and hydrogens indicated by small circles. This layer is identical to *b*–*c* layers of the humite structure.

$AnhB + H_2O$ or $B + stishovite \rightarrow AnhB + H_2O$, could be a mechanism for storage and release of large volumes of water. A possible scenario is that during the early history of the mantle, a magma ocean might first crystallize garnet, then AnhB. On cooling in the presence of water, the reaction would proceed to the left, storing the water in the solids. The difficulty with this scenario is that the hydrous phase B has not been shown to be stable in realistic mantle compositions; its phase relations are little known. We believe that there has been insufficient water present in most experiments to stabilize hydrous phase B. Further work is certainly required to clarify details of the possible phase relations.

Even if high-pressure hydrous silicates were not involved in the formation of primordial surface water, there is circumstantial evidence for their importance in maintaining a hydrosphere. Those planets too small to stabilize phase B in their mantles (Moon, Mercury) are completely dry[1]. The roughly 20-GPa pressures at the core–mantle boundary of Mars would limit the volume of phase B and its surface water has not been replaced. Venus is more complicated. Phase B should be abundant but at a greater depth than on Earth. The quantity of water in the atmosphere will be affected by the efficiency of volcanism in tapping this source and by the extent to which atmospheric water is photodissociated and H_2 lost[19]. □

ACKNOWLEDGEMENTS. We thank D. Veblen for transmission-electron-microscope examinations of phase B. The synthesis of single crystals was performed in the Stony Brook High-Pressure Laboratory, which is jointly supported by NSF and the State University of New York, and the X-ray diffraction data were obtained at the Geophysical Laboratory, which is supported by NSF and by the Carnegie Institution of Washington.

Ecosystem-level patterns of primary productivity and herbivory in terrestrial habitats

S. J. McNaughton, M. Oesterheld, D. A. Frank & K. J. Williams

Biological Research Laboratories, Syracuse University, Syracuse, New York 13244-1220, USA

ECOSYSTEMS are structurally organized as food webs within which energy is transmitted between trophic levels and dissipated into the environment. Energy flow between two trophic levels is given by the amount of production at the lower level and by the proportion of production that is consumed, assimilated and respired at the higher level. Considerable evidence indicates that food-web structure varies predictably in different habitats[1–5], but much less is known about quantitative relationships among food web fluxes. Many of the energetic properties of herbivores in African game parks are associated with rainfall and, by inference, with net primary productivity[6,7]. Respiratory costs per unit production at the consumer trophic level are higher for homeotherms than for heterotherms[8]. Plant secondary chemicals affect herbivore dietary choices[9,10] and the allocation of plant resources to those chemicals varies with resource availability[11]. How these phenomena are translated into ecosystem fluxes is unknown. We present evidence that herbivore biomass, consumption and productivity are closely correlated with plant productivity, suggesting that the latter is a principal integrator and indicator of functional processes in food webs.

A data base was compiled, using sets of data reported in the literature, which combined measurements of herbivore biomass, consumption and/or net secondary productivity with measures of net primary productivity[6,7,12–39]. Unpublished estimates of consumption and net primary productivity in unmanaged African grasslands, from a study described earlier[40], were also included. Cases in which herbivore trophic-level properties were estimated from primary productivity were excluded. Values of herbivore biomass, consumption and net secondary productivity rarely include all populations of herbivores in an ecosystem. Consequently, data were included only if the preponderance of the herbivore level was accounted for in the original study. Only processes occurring above ground were included, as comprehensive below-ground measurements were too few in numbers for quantitative analysis. Fluxes expressed in the literature as units

of mass were converted to energy using standard conversion factors[41-43]. Values of net primary production, net secondary production and consumption are presented in kJ m^{-2} yr^{-1}, and values of herbivore biomass are in kJ m^{-2}. Net primary productivity ranged from ~125 to ~29,000 kJ m^{-2} yr^{-1}. Wide ranges of ecosystems and primary productivities were thus encompassed by the assembled data.

There was a positive association between primary productivity and all three energetic properties of herbivore communities, with different types of ecosystems segregating along common lines (Fig. 1). Herbivore biomass (B) was related (coefficient of determination $r^2 = 0.579$, $P < 0.00001$, degrees of freedom (d.f.) = 49) to net primary productivity (NAP) by

$$\log B = 1.52 (\log \text{NAP}) - 4.79$$

where log indicates common logarithms. Consumption (C) and NAP were related ($r^2 = 0.367$, $P < 0.00001$, d.f. = 67) by

$$\log C = 1.38 (\log \text{NAP}) - 2.32$$

Finally, net secondary productivity (NSP) was related ($r^2 = 0.364$, $P < 0.0001$, d.f. = 34) to NAP by

$$\log \text{NSP} = 1.10 (\log \text{NAP}) - 3.27$$

These data indicate that net energy flux into the food-web base through primary producers is indicative of the three major energetic properties of the trophic level directly above.

Inspection of the goodness of fit between consumption and net primary productivity, revealed that forests fell below the line and grasslands above. Dominance by heterotherm herbivores in forests and homeotherms in grasslands, and the greater prevalence of secondary chemicals in trees than in grasses[11], were initially accepted as explanation of this pattern. Much of the net productivity of forests, however, is confined to wood, a poor quality food[44] largely unavailable to most herbivores. Therefore, we re-examined the relationship, confining net productivity to foliage (NFP). Then, for the larger number of studies in which foliage production and consumption were concurrently measured in forests, the relationship was (Fig. 2)

$$\log C = 2.04 (\log \text{NFP}) - 4.80$$

($r^2 = 0{\cdot}594$, $P < 0.00001$, d.f. = 73). Restricting primary productivity data to foliage, therefore, decreased the unexplained variance substantially by bringing forested ecosystems into line with the patterns across other ecosystems.

We infer that secondary chemicals and differences in the basic physiologies of consumers are much less important influences upon consumption at the ecosystem level than they are at the individual plant and population levels. Other than contributing to an essentially unavailable food class, namely wood[44], secondary chemicals appear to be more important as regulators of what herbivores eat and the types of herbivores prevalent in different ecosystems than as regulators of consumption at the ecosystem level.

All major energetic parameters of the herbivore community—biomass, incoming energy (consumption), and net energy change (net secondary productivity)—were closely associated with net energy flux into the food web. Those relationships based on best fit equations, however, were different. Herbivore biomass increased as a power of net primary productivity as the slope was significantly greater than 1 ($t = 2.80$, $P < 0.01$). The slope of consumption was also greater than 1 ($t = 1.71$, $P < 0.05$), particularly when primary productivity was restricted to foliage ($t = 5.26$, $P < 0.001$). Net secondary production, however, increased linearly with net primary production, with a slope indistinguishable from 1 ($t = 0.38$, P, not significant). This indicates that highly productive ecosystems sustain a larger level of herbivory per unit of primary production than unproductive systems. This larger level of herbivory, however, is accompanied by a lower efficiency in secondary production per unit of consumption, and, as a result, the relationship between net secondary and net primary production is linear.

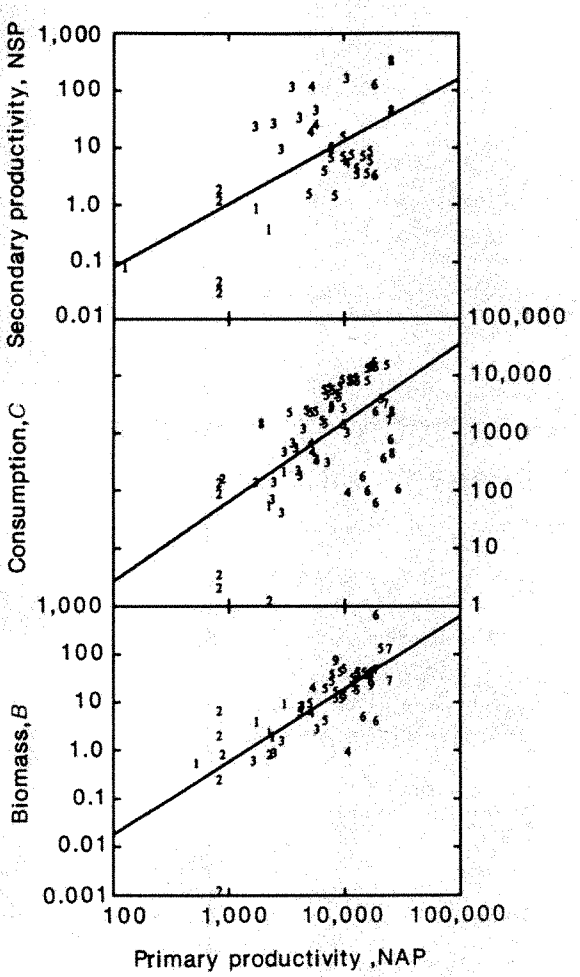

FIG. 1 Relationship between net above-ground primary productivity (NAP, abscissa) and herbivore biomass, consumption, and net secondary productivity (NSP). Units are kJ m^{-2} yr^{-1}, except for biomass which is kJ m^{-2}. Key to type of ecosystem: 1, desert; 2, tundra; 3, temperate grassland; 4, temperate successional old field; 5, unmanaged tropical grassland; 6, temperate forest; 7, tropical forest; 8, salt marsh; and 9, agricultural tropical grassland. The data set consisted of 51 points for B, 69 for C and 35 for NSP.

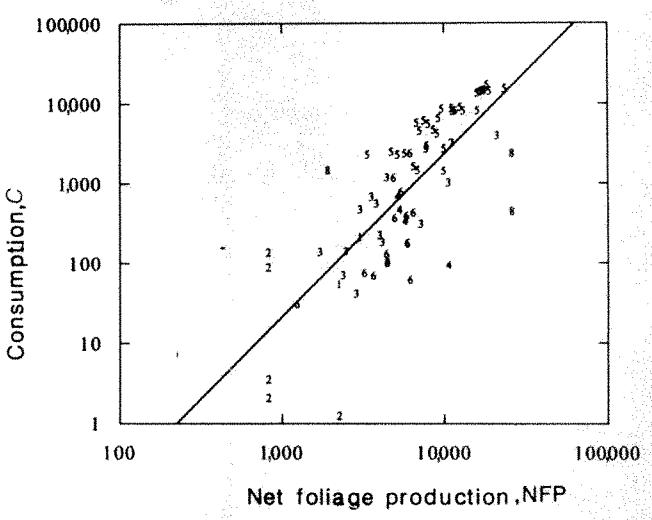

FIG. 2 Relationship between net foliage production (NFP) and consumption (C) by herbivores. Units and ecosystem symbols, as in Fig. 1.

The relationship between consumption and net foliage productivity was heavily influenced, in its upper limit, by a prevalence of data from African game parks, known to support among the highest levels of herbivory yet quantified[45]. It would be desirable to have a greater representation of other systems believed to be highly productive, such as tropical rain forests. Nevertheless, it is recognized that the levels of herbivory are variable but can be extremely high in tropical forest ecosystems[46,47]. High levels of folivory and rapid recycling of nutrients through herbivore wastes, therefore, may be a general feature of highly productive ecosystems[48].

We believe that it would be incorrect to infer from our results that biomass, consumption and production at higher trophic levels are merely a passive consequence of the incorporation of energy and chemicals into the producer level[40]. Higher trophic levels can often have dramatic effects upon food-web structure[49] and on both growth form[50] and productivity of plants[40]. It is useful, we believe, to regard net primary productivity as an integrative ecosystem variable that both influences, and is a reflection of, processes occurring at other trophic levels, some widely removed from primary producers[51].

The relationships documented here between energetic input at the base of the food web (net primary production) and major energetic components of the herbivore trophic level directly above have three major implications for ecosystem science. First, measuring net primary production, which is generally more feasible than measuring processes at the consumer trophic level, and may even be practicable using satellite imagery[52–54], can provide extensive information on whole-system fluxes. The global approach of the International Geosphere–Biosphere program could provide extensive information on general ecosystem processes if the relationships documented here are widely applicable. Second, as food-web structure is related in predictable ways to habitat[1–5], it may be possible to relate structural organizations of food webs to their functional properties in a more integrated, straightforward and predictive fashion. Finally, although our results were confined to only two trophic levels, their regularity indicates that similar patterns will apply to other trophic levels. As, for example, the foliage unconsumed by herbivores will flow into decomposer food webs, the relationship documented here between consumption by herbivores and net primary production indicates that the relative importance of the direct flow to detritus decreases as ecosystem productivity increases. Using the best fit equation, the predicted proportion of annual foliage production processed directly by decomposers, without the intervention of consumers, would decrease from >99% at a net foliage productivity of 500 kJ m^{-2} yr^{-1} to <50% at a net foliage productivity of 20,000 kJ m^{-2} yr^{-1}. □

The secreted form of the Alzheimer's amyloid precursor protein with the Kunitz domain is protease nexin-II

Tilman Oltersdorf, Lawrence C. Fritz, Dale B. Schenk, Ivan Lieberburg, Kelly L. Johnson-Wood, Eric C. Beattie, Pamela J. Ward, Russell W. Blacher, Harry F. Dovey & Sukanto Sinha*

Athena Neurosciences, Inc., 800 F Gateway Boulevard, South San Francisco, California 94080, USA

THE A4 protein (or β-protein) is a 42- or 43-amino-acid peptide[1] present in the extracellular neuritic plaques in Alzheimer's disease and is derived from a membrane-bound amyloid protein precursor (APP). Three forms of APP have been described[2–7] and are referred to as APP695, APP751 and APP770, reflecting the number of amino acids encoded for by their respective complementary DNAs. The two larger APPs contain a 57-amino-acid insert with striking homology to the Kunitz family of protease inhibitors[5–7]. Here we report that the deduced amino-terminal sequence of APP is identical to the sequence of a cell-secreted protease inhibitor, protease nexin-II (PN-II)[8]. To confirm this finding, APP751 and APP695

FIG. 1 Alignment of the N-terminal sequence of PN-II with the deduced N-terminal sequence (residues 18–50 of primary transcript) of APP[9,10]. The disagreement at residue 27 of PN-II is probably due to a mis-determination during Edman degradation.

cDNAs were over-expressed in the human 293 cell line, and the secreted N-terminal extracellular domains of these APPs were purified to near homogeneity from the tissue-culture medium. The relative molecular mass and high-affinity binding to dextran sulphate of secreted APP751 were consistent with that of PN-II. Functionally, secreted APP751 formed stable, non-covalent, inhibitory complexes with trypsin. Secreted APP695 did not form complexes with trypsin. We conclude that the secreted form of APP with the Kunitz protease inhibitor domain is PN-II.

The sequence of APP was compared by computer-assisted methods with sequences in the Protein Identification Resource (PIR) protein-sequence database. Surprisingly, amino-acid residues 18 to 50 of APP are identical to the N-terminal 33-amino-acid sequence of PN-II (ref. 8; Fig. 1) except at position 27 of PN-II; the residue at this position is a phenylalanine in contrast to the histidine at the corresponding position of APP. This difference is not definite, however, because the identification of residue 27 was in doubt in the original publication of the sequence of PN-II. The N-terminal 17 amino acids of the APP sequence, which precede the PN-II homology region, correspond exactly to the presumed signal sequence, which is cleaved off during translocation into the endoplasmic reticulum[9,10].

Protease nexins are a heterogeneous group of serine protease inhibitors secreted by a number of cell types in culture (see refs 11–13 for reviews). PN-II was first isolated by its property of forming complexes with epidermal growth factor-binding protein, EGF-BP, a pro-EGF processing serine esterase[14–17]. PN-II was subsequently purified to homogeneity from conditioned medium of primary human fibroblasts[8], and shown to additionally form complexes with trypsin and with the gamma subunit of nerve growth factor (NGF).

To further establish the relationship between PN-II and APP we co-transfected 293 transformed human-embryonic-kidney cells with pSV2-*neo* and cDNAs coding for APP695 and APP751 under the control of the human cytomegalovirus promoter/enhancer, which were then over-expressed as in stable clones[18]. The secreted form of APP was detected in tissue-culture medium by western blotting, using an affinity-purified polyclonal antibody raised against a bacterial fusion protein containing the extracellular part of APP from amino-acid residues 444 to 592 (anti-secreted APP) (Fig. 2). The apparent relative molecular masses (M_r) of secreted APP695 and APP751, determined by SDS-PAGE under reducing conditions, were ~110,000 (110 K) and 124,000 (124 K), respectively (Fig. 2*a*; Bio-Rad standards, high range; Amersham protein standards led to estimates of M_r of 9–10 K less). The reported M_r of PN-II under these conditions is 112 K (ref. 8). As PN-II has been shown to bind dextran sulphate-Sepharose with high affinity, we used dextran sulphate-Sepharose chromatography, followed by DEAE-Sepharose

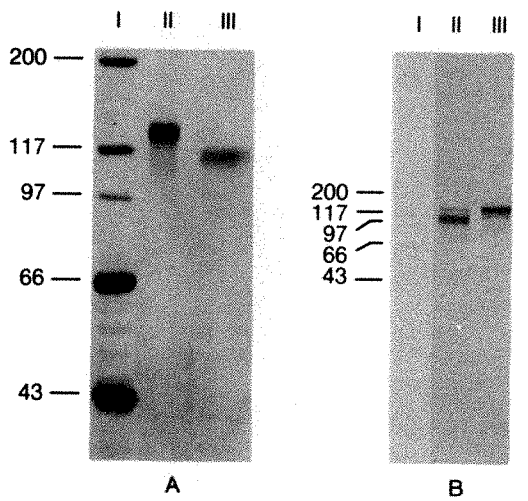

FIG. 2 *a*, SDS-PAGE analysis of purified secreted APP695 and APP751. Lane I, Bio-Rad high-range protein standards, 250 ng of each (myosin, 200 K; beta-galactosidase, 117 K; phosphorylase *b*, 97 K; BSA, 66 K; and ovalbumin, 43 K; lane II, secreted APP751 (175 ng); lane III, secreted APP695 (150 ng). *b*, Western blot of purified secreted APP695 and APP751. Lane I, Bio-Rad high range protein standards; lane II, secreted APP695; lane III, secreted APP751.

METHODS. Purification of secreted APPs. 293 cells stably transfected with either APP695 or APP751 cDNAs were grown in serum-free F12/Dulbecco's minimum essential medium (1:1) supplemented with 50 μM ethanolamine, 10 nM sodium selenite and 1 mM sodium pyruvate. Conditioned medium (500 ml) was collected from each cell type, then centrifuged and filtered. The clear medium was then loaded on to a 1.6 × 15-cm dextran-Sepharose column (prepared as described previously[8]), then washed with 50-column volumes of 20 mM potassium phosphate buffer, pH 7.4 and 75 mM NaCl. The column was then eluted with a linear gradient to 1.2 M NaCl in the same buffer. Fractions containing secreted APPs were identified by western blotting using affinity purified rabbit antisera raised to a bacterially expressed fusion protein containing the portion of APP amino-acid sequence from residue 444–592 (restriction sites *Bam*Hi to *Bgl*II). This cDNA fragment was inserted in the *Bam*HI restriction site of plasmid pEx × 10-mer (ref. 28), and a stop codon was introduced by making the plasmid linear using the *Xba*I site, filling in with Klenow polymerase, and religating the resulting blunt ends. The resulting plasmid, pBX5, was used to obtain a fusion protein with a 100 amino-acid bacteriophage MS2 polymerase N-terminal leader sequence by induction of the bacteriophage λP_L promoter contained in these plasmids, and partially purified by urea extraction as described previously[28]. Rabbit antisera raised against this fusion protein (anti-pBX5) were affinity purified by first removing non-relevant IgG over a column containing immobilized bacterially expressed pEx10-mer (containing the MS-2 leader peptide), then by binding to, and eluting from, a second column containing immobilized partially purified pBX5. Pooled fractions from the dextran-Sepharose elutate were then adjusted to the conductivity of 10 mM Tris buffer, pH 8, and NaCl (50 mM), by dilution with 10 mM Tris, pH 8, and then loaded onto a 1.6 × 10-cm DEAE-Sepharose column equilibrated with this buffer. The column was eluted with a linear gradient to 1.2 M NaCl, and fractions containing secreted APPs were again identified by western blotting and then pooled. Protein concentrations in the pooled fractions were estimated by the BCA protein assay (Pierce). Protein (150–175 ng) from each pool was analysed by SDS-PAGE, on a 12 × 18-cm acrylamide gel (10%), after denaturing in Laemmli sample buffer with DTT (100 mM). After electrophoresis, the gel was silver-stained[29]. For the western blot analysis, ~150 ng of purified secreted APPs were electrophoresed on a 12% acrylamide 6 × 9-cm SDS-PAGE, in a Bio-Rad Mini-Protean gel system, and the protein transferred to Immobilon (Millipore) membrane. The membrane was then incubated with anti-pBX5 (1:500), and the western blot developed using goat anti-rabbit IgG-alkaline phosphatase (Bio-Rad). The sensitivity of the western blot technique was shown by the detection of contaminating secreted APP751 in the purified secreted APP695 fraction, which is present at a level below the detection limit of the silver-staining method in *a*, lane III.

chromatography, to purify secreted APPs from serum-free conditioned medium of transfected cells (Fig. 2). The analysis of the two purified secreted APPs by SDS-PAGE silver staining and western blotting is shown in Fig. 2.

Aliquots of the purified secreted APPs were then tested for their ability to inhibit the esterolytic activity of pancreatic trypsin (Fig. 3*a*). Secreted APP751 potently inhibited trypsin, whereas secreted APP695 had no discernible inhibitory activity.

HPLC-gel exclusion chromatograpyy (GEC) was used to further confirm that a quantitative 1:1 complex formation of trypsin with secreted APP751 occurs in physiological buffer conditions. Porcine pancreatic trypsin was radio-iodinated by the lactoperoxidase-glucose oxidase method[19], and affinity purified on a column of Aprotinin-Sepharose[20]. Purified secreted APP751 was incubated with a stoichiometric mixture of cold trypsin and 125 I-labelled trypsin, and the mixture was then resolved on an HPLC-GEC column equilibrated with phosphate HEPES (20 mM pH 7.4) and NaCl (150 mM 0.5 M) (Fig. 3*b*). In the absence of added APP751, free iodinated trypsin eluted with a peak in fraction 19. Pre-incubation with secreted APP751 led to virtually quantitative peak elution in fraction 12, corresponding to an apparent higher M_r and indicating stable complex formation.

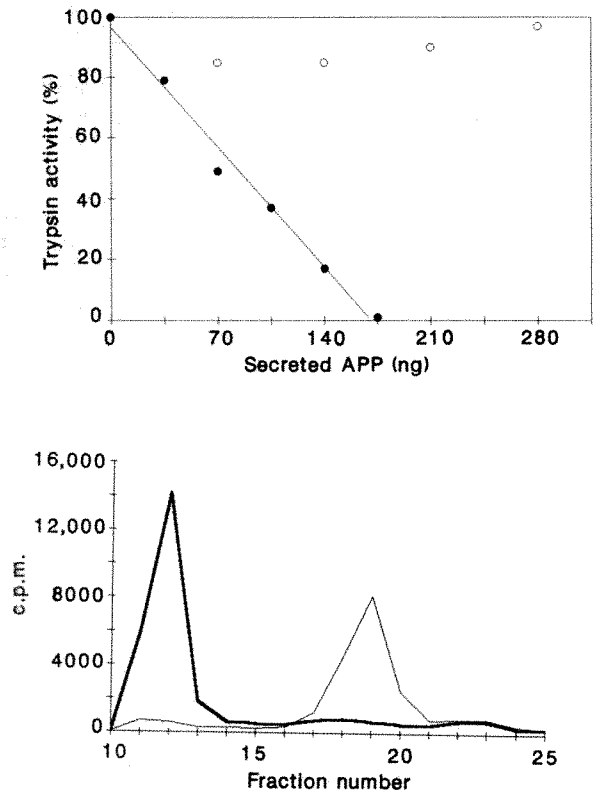

FIG. 3 *a*, Inhibition of the amidolytic activity of bovine pancreatic trypsin by secreted APPs. Aliquots (40 ng) of bovine pancreatic trypsin were incubated with increasing amounts of secreted APPs (APP751, 0–175 ng; APP695, 0–280 ng) in a total volume of 100 μl, containing 0.1 M HEPES, pH 7.25, and 1 mM $CaCl_2$. After 5 min, residual trypsin esterolytic activity was assayed by diluting 10 μl of the mixture into 140 μl of assay solution containing 0.25 mM Z-valyl-glycyl-arginyl-p-nitroanilide, in 0.1 M HEPES, pH 7.25, and 1 mM $CaCl_2$, and the rate of hydrolysis of the substrate monitored by the increase in absorbance at 405 nm. Kinetic assays were done in microtitre plate wells in a Molecular Devices V^{max} machine. Rate values were converted to 'percent trypsin activity' relative to the rate of hydrolysis of substrate by trypsin in the absence of addition of secreted APP. The inhibition of trypsin activity by secreted APP751 (●) could be fitted to a linear regression line, and showed virtually 1:1 (molar ratio) inhibition of trypsin activity by secreted APP751. By contrast, secreted APP695 (○) had no significant effect on trypsin activity. *b*, HPLC-GEC of complexes of trypsin with secreted APP751. Trypsin (40 ng) was mixed with 1 ng radio-iodinated trypsin (50,000 c.p.m.) then mixed either with 20 mM HEPES, pH 7.25, and 0.5 M NaCl to a final volume of 100 μl, or with 150 ng purified secreted APP751 in the same buffer. The mixtures were then injected onto a Bio-Rad TSK125 column, 0.78 × 25 cm, equilibrated with the same buffer at a flow rate of 0.5 ml min^{-1}. Fractions (0.5 ml) were collected and counted for ^{125}I activity directly in a Beckman Gamma Counter. Free trypsin, fine line; APP751, bold line.

To test whether the inhibition of trypsin by secreted APP751 was accompanied by the formation of complexes stable to denaturing SDS-PAGE, as has been claimed for complexes of PN-II with trypsin and the other arginine esterases[8], purified secreted APP751 was briefly incubated with a sub-stoichiometric amount of trypsin, mixed in a 1:1 ratio with twofold concentrated Laemmli sample buffer[21], heated at 60 °C for 5 min, then analysed by non-reducing SDS-PAGE. We found that complexes treated in this way were not stable to denaturing SDS-PAGE, because the trypsin and the secreted APP751 migrated with their usual independent mobilities (Fig. 4, lane 3B). We were also unable to show SDS stability using a Bistris-Bicine buffer SDS-PAGE system[22], similar to a Monotris-Bistris buffer system used by Knauer *et al.*[14], which was claimed to enhance SDS stability of PN-II-esterase complexes. When the trypsin-secreted APP751 mixtures were incubated in Laemmli buffer at room temperature, however, a higher M_r complex of trypsin with secreted APP751 (Fig. 4, lane 3A) was detected. With purified secreted APP695 we were unable to detect any complex formation; in fact, the brief incubation with trypsin before electrophoresis led to partial fragmentation of this form of the secreted APP (Fig. 4, lanes 4A and B). Only the 751 form, therefore, is capable of inhibiting esterolytic and proteolytic activities of trypsin, by forming tight and stable complexes with the protease through non-covalent interactions.

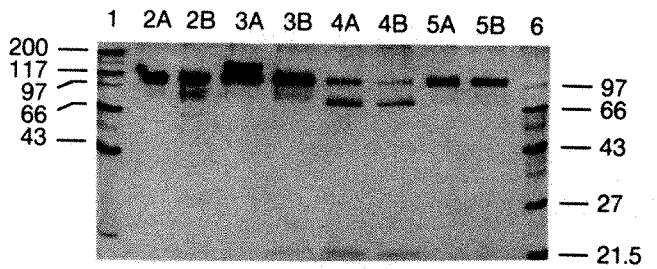

FIG. 4 SDS-PAGE analysis of trypsin and secreted APP mixtures. Lanes 1 and 6, Bio-Rad high protein standards (as described in Fig. 2) and low range protein standards (phosphorylase *b*, 97 K; bovine serum albumin, 66 K; ovalbumin, 43 K; carbonic anhydrase, 27 K; and soybean trypsin inhibitor, 21.5 K), respectively. Lanes 2A and B, Secreted APP751. Lanes 3A and B, Secreted APP751 and trypsin. Lanes 4A and B, secreted APP695 and trypsin. Lanes 5A and B, secreted APP695. All 'A' lanes indicate samples taken up in Laemmli buffer and not heated, and 'B' lanes refer to identical samples heated to 60 °C before electrophoresis. Secreted APP (150 ng) was mixed with either buffer (20 mM HEPES, pH 7.25) or bovine pancreatic trypsin (40 ng) in duplicate and on ice for 2 min. Tosyl-lysyl-chloromethylketone was then added to 1 mM to block any uncomplexed trypsin. Mixtures were taken up in non-reducing Laemmli buffer, and either heated at 60 °C for 5 min or left at room temperature before electrophoresis. The samples were run on 12% acrylamide SDS-PAGE in a Bio-Rad Mini-Protean apparatus and then silver-stained[29]. In Lane 3A a high relative molecular mass complex of trypsin with secreted APP751 is visible, migrating with a lower mobility than uncomplexed secreted APP751. Under denaturing conditions, however, this complex is not detectable and a free trypsin band is visible at a position corresponding to a M_r of 22 K (lane 3B). With secreted APP695 no complex is detectable and trypsin migrates at its expected position, whether the sample had been previously heated (lane 4B) or not (lane 4A). Comparison with lanes 5A and B shows that the brief incubation with active trypsin in fact led to rapid fragmentation of this secreted APP. An inhibitory complex is formed with secreted APP751, because APP751 is unaffected by its incubation with trypsin.

The sequence identity, similar relative molecular masses, quantitative binding to, and elution with increasing ionic strength from the dextran sulphate matrix, and stable inhibitory complex formation with trypsin, all indicate that the secreted version of APP containing the Kunitz inhibitor domain is indeed PN-II. At the moment we cannot determine if the described PN-II from human fibroblasts[8] is APP751 or APP770; both of these APPs contain the Kunitz domain and differ only by 19 amino acids. It is probable that material purified from fibroblasts contains a mixture of the two, because all cell types examined to date by S1 nuclease protection assays make both APP751 and APP770, and both of the proteins are poorly resolved by SDS-PAGE[23].

The dissociation of the secreted APP751–trypsin complex under denaturing conditions is not, at first sight, in accord with earlier reports[8,14]. These described PN-II as a 'serpin' inhibitor (see ref. 24 for review) that forms covalent bonds with target proteases stable to denaturing SDS-PAGE, as does protease nexin I (PN-I), for example[25]. This classification was based, however, entirely on the detection of an 'SDS-stable' complex of protease with PN-II electrophoresed after mild denaturation[8,14]. Our results indicate that although complexes of trypsin with PN-II may seem to be SDS-stable if mild denaturing conditions are used, they do not resist heating in 1% SDS, which is the accepted criterion for serpin–protease complex stability[26]. There is, therefore, no convincing evidence that the original classification of PN-II as a serpin[8] is correct.

It is ironic that a functional relationship between nexins and APPs containing Kunitz domains has been speculated previously[27]. Previous comparisons, however, were made between APP and PN-I, a cell-secreted protease inhibitor with neurite outgrowth promoting activity[13], but which does not have any significant sequence homology with PN-II. The identification of a secreted APP as PN-II shows that Kunitz inhibitors may also be used by cells as 'nexins', and that using PN-I as a mechanistic prototype for uncharacterized potential nexins may be misleading.

The identification of a secreted form of APP as a protease nexin raises new questions regarding the pathogenesis of Alzheimer's disease. It indicates that not only may the protease inhibitory activity of APP be important, but that the reuptake and degradation of APP–protease complexes, characteristic of PN-I, may also be of consequence. In addition, the possible role of PN-II on the uptake of growth-factor-associated serine esterases may have implications for Alzheimer's disease, where changes in such factors could influence the degree of cell survival, neuritic outgrowth, and other cellular processes. Identification and characterization of such variables could lead to a better understanding of the disease and ultimately to its therapy. □

Developmental alterations in the frequency map of the mammalian cochlea

Stephen M. Echteler, Ellis Arjmand & Peter Dallos

Auditory Physiology Laboratory, Department of Neurobiology and Physiology, Northwestern University, Evanston, Illinois 60208, USA

THE position of an auditory hair cell along the length of the cochlea determines the sound frequency to which it is most sensitive. Receptors located near the proximal end (base) of the cochlea are maximally stimulated by high-frequency sounds; those occupying successively more distal (apical) positions respond best to progressively lower frequencies[1]. At present, it is unclear how this frequency place map emerges with respect to the development of the cochlea. It has been suggested, on the basis of acoustic trauma experiments with developing chicks[2] and cochlear potential recordings[3–5] from developing gerbils, that this map may arise through systematic changes in the spatial encoding of frequency along the cochlea. Others have inferred from frequency tuning curves derived from auditory-nerve recordings in developing mammals[6] and chicks[7], that the cochlear frequency-place map remains stable throughout development. We analysed frequency tuning curves obtained from gerbil spiral ganglion cells at a constant location within the basal cochlea, and report here that these cells undergo significant increases (up to 1.5 octaves) in their best-response frequencies between the second and third weeks of postnatal life. These recordings provide direct evidence for developmental changes in the tonotopic organization of the mammalian cochlea.

The Mongolian gerbil (*Meriones unguiculatus*) is useful for studies of auditory development because it is of a species in which hearing matures after birth. The first sound-evoked cochlear potentials are recorded on postnatal day 12 (ref. 8), by which time the cochlea is already its mature length (S. Fikret and J. Siegel, unpublished results; D. Harris *et al.*, manuscript in preparation). Two days later, action potentials can be routinely recorded in the auditory nerve[9]. In previous experiments, cochlear potential recordings obtained from the mid-basal turn in an age-graded series of gerbils have shown that the best-response frequency of this recording site changes systematically from ~5 kHz at 13 days after birth to ~17 kHz at 30 days after birth[3–5]. Similar alterations in the tonotopic organization of several gerbil auditory brainstem nuclei have also been noted during this time period[10,11]. Because cochlear length is fully developed and the middle ear is essentially mature by postnatal day 14 (ref. 12), these data imply some sort of reorganization of the high-frequency responsive region of the mammalian cochlea during development. To directly test this hypothesis, we recorded frequency tuning curves from single spiral ganglion cells of known location within the cochlea to assess their best-response frequencies at different stages of development.

Experiments were on gerbils ranging in age from 14 to 53 days. Figure 1 shows the recording approach to Rosenthal's canal within the basal turn of the gerbil cochlea. The recording

site, illustrated schematically, was verified in each case by extracellular injection of horseradish peroxidase. At all ages studied, the peripheral neurites of labelled spiral ganglion cells were orientated radially within the cochlear spiral and projected to inner hair cells located 2.7 ± 0.2 mm from the basal end of the basilar membrane. Total basilar membrane length averages 12.1 mm in this species[13].

The postnatal development of frequency tuning for single spiral ganglion cells at this recording site is illustrated in Fig. 2. At 14 days after birth, frequency tuning (neural isoresponse) curves possessed a broadly-tuned low-frequency 'tail' and a more sharply-tuned high-frequency 'tip' centred between 5 kHz and 7 kHz (Fig. 2*a*). Neural thresholds at this age exceeded 90 dB. Over the next three postnatal days, the tip of the tuning curves obtained from neurons at this location shifted progressively upwards in frequency and downwards in threshold (Fig. 2*b*, *c*). Tuning curve tails, however, remained relatively stable in their morphology throughout this period, undergoing only a 20-dB reduction in threshold. Neural tuning had stabilized at this location by postnatal day 17. To emphasize this point we have superimposed the tuning curves derived from 17-, 22- and 53-day old animals (Fig. 2*c*). This also illustrates both the consistency of our recording site and the homogeneity in tuning-curve morphology observed in adult animals.

In Fig. 3*a* the characteristic frequencies (CF, the frequency of the lowest threshold) of individual spiral ganglion neurons are plotted as a function of postnatal age. Within a three-day period, from postnatal day 14 to 17, cochlear neurons at this recording location within the basal turn undergo a substantial increase (1.5 octaves) in their CF. The rate at which the CF matures, however, is not constant throughout this postnatal period. The most dramatic increase occurred within a 24-hour period between 14 and 15 days after birth and amounted to ~1.0 octave. Over the next two days, the best-response frequency for neurons at this cochlear location continued to increase by ~0.5 octave until mature CFs were achieved on postnatal day 17. During this time, neural thresholds at CF decreased by over 80 dB (Fig. 3*b*).

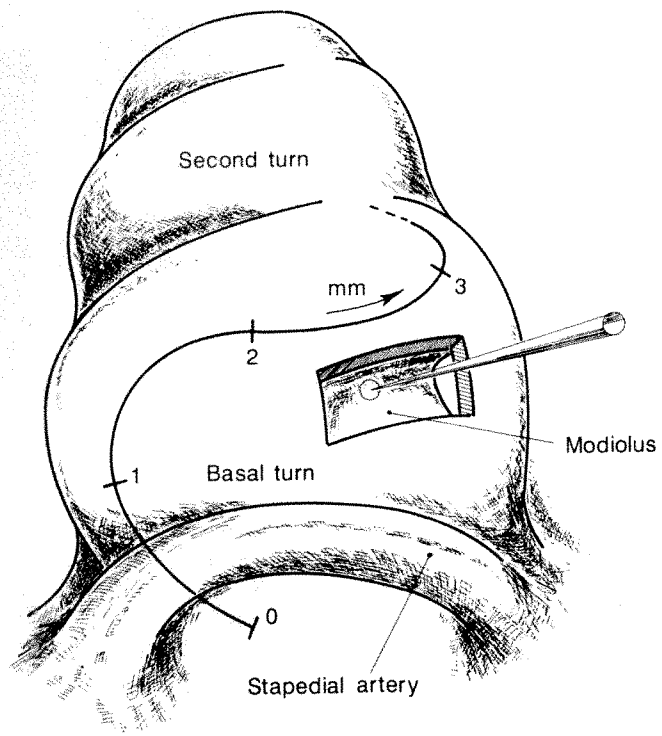

FIG. 1 Schematic illustration of the spiral ganglion recording site within the basal turn of the gerbil cochlea. The basilar membrane is depicted as a spiraling solid line with distance from its base indicated in millimetres. A microelectrode enters scala tympani through a window in the cochlear capsule and passes through an opening in the bone overlying Rosenthal's canal.

METHODS. Gerbils were anaesthetized by injection of sodium pentobarbital (48 mg kg^{-1}, intraperitoneal) and, after the insertion of a tracheal cannula, the right pinna was removed to allow direct coupling of the sound delivery system to the external meatus. The cochlea was exposed using surgical procedures previously described[18]. A fine scalpel blade was used to open a rectangular window (~0.8 mm × 0.5 mm) in the cochlear capsule overlying scala tympani of the basal turn. This window was positioned ~180° apical to the round window and its removal allowed visualization of an 800-μm segment of the modiolus within the middle third of the basal turn. Rosenthal's canal, which contains the cell bodies of the spiral ganglion neurons, was easily distinguished as a pearl-grey stripe, ~250 μm wide, coursing through the white modiolar bone. Using visual landmarks, such as modiolar blood vessels, a 100-μm hole was made in the bone overlying a specific portion of Rosenthal's canal using a sharpened insect pin mounted on a three-stage micromanipulator. After surgery, the animal was placed on a vibration-damped table within a double-walled sound-isolation chamber.

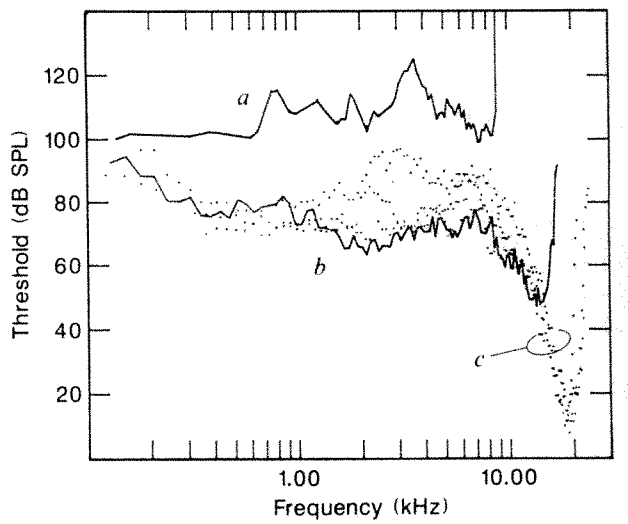

FIG. 2 Tuning curves obtained from single spiral ganglion neurons at the recording location described in Fig. 1, 14 days after birth (*a*), 15 days after birth (*b*), and 17, 22, and 53 days after birth (*c*).

METHODS. Acoustic stimuli were delivered through a Beyer DT48 earphone sealed to the external meatus. Stimulus sound pressure level was monitored at the mouth of this tube, near the tympanum, through a concentrically placed calibrated probe tube coupled to a Knowles microphone. Auditory stimuli were tone-bursts (100-ms duration; 2.5-ms rise/fall time) ranging in frequency from 100 Hz to 21 kHz and delivered at a rate of 3 per second. Stimulus frequency and intensity were controlled by a PDP 11/34 digital computer. Grason-Stadler logic elements controlled stimulus shaping and presentation rate. Single unit activity was recorded with glass microelectrodes filled with NaCl (2M) (impedances of 40–90 mΩ). Neural discharges were amplified and then shaped by a Schmitt trigger, which provided the input to a microprocessor-based event-time counter interfaced to the computer. An automated paradigm was used to derive frequency tuning curves. In this paradigm, the number of spikes was compared in two sequential 50-ms time-windows. A tone was present only during the first window. Threshold was defined as the stimulus intensity required to elicit at least two more spikes in the first window than the second. Stimulus intensity was reduced or increased in 2-dB steps until the threshold criterion was met once. Threshold was determined at up to 135 discrete frequencies per tuning curve. After neural recording, a solution of horseradish peroxidase (Sigma VI, 10% w/v) was iontophoretically ejected (+2 μA for 15 min; 200-ms pulses, 50% duty cycle) from a glass micropipette (5 μm tip) to mark the recording location within the spiral ganglion. One to three hours after horseradish peroxidase injection, the animals were killed by overdose of anaesthetic and perfused through the heart with 0.9% saline followed by 3% glutaraldehye in 0.1 M phosphate buffer. The horseradish peroxidase histochemistry of the cochlea was observed by the reaction with diaminobenzidine with cobalt chloride intensification[19]. Cochleae were embedded in Epon and prepared for viewing as a surface preparation. The position of the recording location within the cochlear spiral was computed from tracings made of the basal turn.

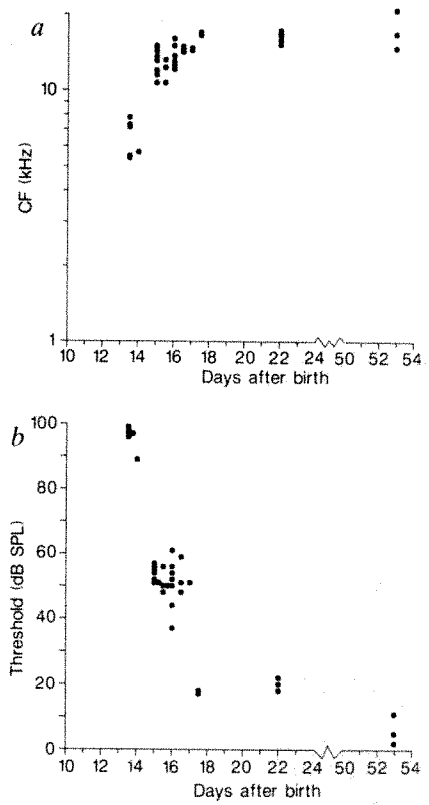

FIG. 3 The characteristic frequencies (CF) of individual spiral ganglion cells (*a*) and their neural thresholds at CF (*b*) as a function of postnatal age at the recording site described in Fig. 1. Breeding colonies were checked twice daily. Age was determined with an accuracy of ±12 hours.

These results confirm the hypothesis that mature tonotopy develops within the inner ear through systematic changes in the spatial encoding of frequency along the cochlear duct[2]. As noted earlier, the first evidence for ontogenic changes in the frequency distribution of the mammalian ear was provided by cochlear potential measurements in developing gerbils[3-5]. The relevance of those studies to the emergence of cochlear nerve responses has been questioned[14], however, because they relied on measurements of cochlear microphonic and summating potentials, which are generated primarily by outer hair-cell receptors[15], whereas auditory nerve recordings reflect inner hair-cell responses[16]. The results reported here provide direct evidence for developmental changes in tonotopic organization within the auditory nerve. Moreover, the magnitude and time course of the changes in frequency tuning observed in our spiral-ganglion recordings are in substantial agreement with those obtained from cochlear potential measurements, thereby providing additional support for the value of those techniques in mapping functional changes within the developing auditory periphery.

The extent to which our results can be generalized to other mammalian species remains to be determined. Our present knowledge of the functional development of the cochlear nerve in mammals has been derived from extracellular recordings from single or multiple nerve fibres within the auditory nerve trunk. Such techniques, unlike those that we used, cannot verify the exact site within the cochlear spiral from which the neurons recorded from originate. Nevertheless, the emergence of response properties for particular frequency bands has been inferred from many of these studies by comparing tuning curves with the same apparent CF at different developmental ages[6,17]; this inference presumed a stable cochlear frequency map. If alterations in the frequency-place map such as those reported here are a common feature during cochlear development in mammals, then such studies will require re-evaluation. □

DURING the development of the vertebrate nervous system, many neurons depend for survival on interactions with their target cells[1]. Specific proteins are thought to be released by the target cells and to play an essential role in these interactions. So far, only one such protein, nerve growth factor, has been fully characterized. This has been possible because of the extraordinarily (and unexplained) large quantities of this protein in some adult tissues that are of no relevance to the developing nervous system[2]. Whereas the dependency of many neurons on their target cells for normal development, and the restricted neuronal specificity of nerve growth factor have long suggested the existence of other such proteins, their low abundance has rendered their characterization difficult. Here we report the full primary structure of brain-derived neurotrophic factor. This very rare protein is known to promote the survival of neuronal populations that are all located either in the central nervous system or directly connected with it[3]. The messenger RNA for brain-derived neurotrophic factor was found predominantly in the central nervous system, and the sequence of the protein indicates that it is structurally related to nerve growth factor. These results establish that these two neurotrophic factors are related both functionally and structurally.

Brain-derived neurotrophic factor (BDNF) was purified from pig brain[4,5], and a partial amino-acid sequence determined both from the N-terminal end and from fragments purified after cleavages (Table 1). The longest sequence, compiled from several overlapping fragments, was used to synthesize two sets of oligonucleotides that were used to prime the amplification of a pig genomic template using the polymerase chain reaction (PCR)[6]. The nucleotide sequence between the two primers was determined and used to synthesize specific primers for further PCRs on a complementary DNA template obtained by reverse

primer. An amplification reaction was performed using this template with oligo 3 and oligo 5 as primers and cloned into a pBluescript vector. The inserts of several 3′- and 5′- clones were sequenced.

FIG. 2 Sequence comparison between NGF and BDNF. Areas with more than two amino acids found at identical positions are indicated by shading. The sequences start with the first amino acids of the mature proteins and end with the last ones before the stop codons. Fifty-one amino acids are common to BDNF and the various NGFs[11], including the six cysteine residues (see text for details). Asterisks indicate gaps introduced to optimize matching.

transcription of total RNA isolated from the superior colliculus of the pig brain. This brain area was used because retinal ganglion cells are known to respond to BDNF[7]; the superior colliculus, one of the major targets of retinal ganglion cells[8], was therefore assumed to be a site of BDNF synthesis. The nucleotide sequence (resulting from combined cDNA clones) shows an open reading frame coding for a protein of 252 amino acids, starting with the first methionine codon found after four in-frame stop codons (Fig. 1). The N terminus of mature BDNF starts after an Arg–Arg cleavage sequence. Both the predicted size of mature BDNF (relative molecular mass 13,511) as well as its calculated isoelectric point (pI = 9.99) agree well with the results of previous determinations made with BDNF purified by two-dimensional gel electrophoresis[4]. The partial amino-acid sequence of BDNF determined by protein microsequencing (singly underlined in Fig. 1) is in complete agreement with the predicted amino-acid sequence deduced from the cDNA sequence. To demonstrate that this open reading frame is necessary and sufficient to direct the synthesis of biologically active BDNF, we performed the PCR with oligonucleotide primers corresponding to the 5′- and 3′-most regions of the sequence coding for BDNF on a pig genomic template (Table 2). The resulting amplified product had a size corresponding to that predicted from the cDNA sequence, indicating that no introns are present in this portion of the BDNF gene. The amplified product was cloned into an expression vector and introduced into monkey kidney COS cells. The biological activity secreted by these cells into the culture medium (collected after 48 h) was assayed using spinal sensory neurons from embryonic chick. Quantitation of the neuronal survival in this medium indicated that the biological activity was indistinguishable from that of the purified protein (Table 2). The effects were quantitatively similar to those obtained with the purified protein when used at concentrations giving maximal neuronal survival,

Amino acids represented by the single-letter code. BDNF was either sequenced directly (two runs with 50 and 70 pmole, as determined by amino-acid analysis, with initial yield of 40 and 50 pmole respectively for the N-terminal histidine) or cleaved (5–10 μg BDNF, from five different preparations) as follows: V8, 1 μg *Staphylococcus aureus* V8 (Miles) was added to 5 μg BDNF in 0.2 M NH_4CO_3, pH 8.0, containing 10% acetonitrile (total volume, 50 μl) and incubated overnight at room temperature; trypsin, 1 μg tosyl phenylalanine chloromethyl ketone (TPCK)-treated trypsin (bovine pancreas, Sigma Type XIII) was added to 8 μg BDNF in Tris-HCl (0.1 M, pH 8.0) containing 10 mM $CaCl_2$ (total volume, 40 μl) and incubated overnight at 37 °C; cyanogen bromide (CNBr), 10 μg BDNF were incubated for 3 h at room temperature (total volume, 60 μl) with 10% (w/v) CNBr in 70% (v/v) formic acid (final concentrations). After addition of 500 μl H_2O at the end of the reaction, the sample was concentrated to 50 μl in a speed-vac. Tris-HCl (50 μl, 1.0 M, pH 8.0) were added together with 5 μl β-mercaptoethanol and the sample was incubated overnight at 37 °C. After addition of 5 μl iodomethane, the sample was evaporated to dryness on a speed-vac. Reduction and alkylation of BDNF after CNBr cleavage were found to be necessary: no fragments were obtained without reduction, as shown by HPLC and Swank–Munkres SDS-gel electrophoresis[15]. This indicates that disulfide bridges are present in BDNF. After all cleavages, the dried samples were resuspended in 0.1% trifluroacetic acid (TFA) and applied onto a reverse phase C8 microbore HPLC column (Applied Biosystems) and the peptides eluted at 0.1 ml min^{-1}, using a 60-min linear gradient of 0–60% acetonitrile in 0.1% TFA. Detection was at 214 nm with a Waters 441 ultraviolet detector. The peptides were sequenced by automated Edman degradation on a gas-phase microsequencer (model 470A Applied Biosystems), according to Hewick[16] and Hunkapiller[17]. Detection of the phenylthiohydantoin amino acids was as described[18].

TABLE 2 Survival of cultured chick sensory neurons

	COS medium (final dilution)		
	1:20	1:50	1:200
		Cell count	
COS^+		2,510 ± 263	2,833 ± 171
COS^-	211 ± 16		
COS	250 ± 87		
BDNF + COS^+		2,516 ± 209	
NGF + COS^+		5,770 ± 72	
BDNF alone		**2,718 ± 424**	

E8 chick spinal sensory neurons were plated (6,000 per well), incubated for 24 h and counted after 24 h (ref. 9). The values are the means of triplicate determinations ± s.d. BDNF and NGF were used at 1 ng ml^{-1}, concentrations at which maximal neuron survival is observed with either factor. COS^+ and COS^-, cells transfected with plasmids containing the BDNF insert in the sense or antisense orientation, respectively. COS, non-transfected cells. At dilutions higher than 1:20, no survival above that of the control was seen with either COS^- or COS conditioned medium. In all experiments without NGF, a monoclonal anti-NGF antibody[19] was used at 1 μg ml^{-1}. The sequence corresponding to pig preproBDNF was obtained by using the oligonucleotide primers ATAATCTAGATGACCATCCTTTTCCTT (sense) and ATAATCTAGACATCTTCCCCTCTTAAT (antisense) in a PCR using 1 μg of pig genomic template (each primer had an added *Xba*I site). After digestion with *Xba*I, the amplified DNA was ligated in the *Xba*I site of the plasmid pCMV[20] and E-1 bacteria transfected by electroporation. Plasmid DNA was cut with both *Xba*I and *Pst*I. The size of the resulting products allowed us to determine the orientation of the inserts, and both plasmids were used to transfect COS cells by the calcium phosphate method[21], and the growth medium (consisting of DMEM and 10% FCS) collected after 24 h.

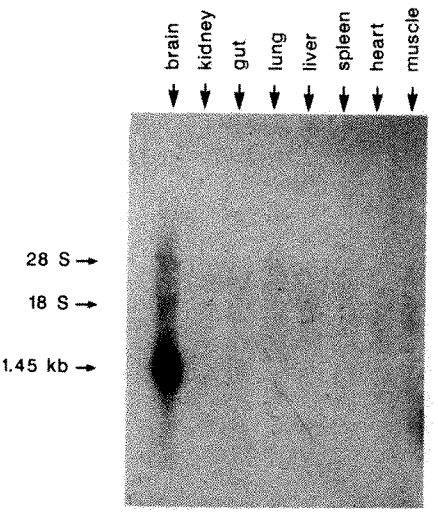

FIG. 3 Northern blot analysis. From each tissue, 20 μg total RNA was applied per lane and hybridized with a ^{32}P-labelled cRNA mouse BDNF probe. Note that a strong signal can be seen at a position corresponding to ~1.45 kb with brain tissue, but not with the seven other tissues analysed. Muscle is thigh skeletal muscle.

METHODS. Total RNA was extracted from various tissues of adult female mice according to Okayama[28]. Electrophoresis was according to Lehrach[29] on 1.3%-agarose–formaldehyde gels. The RNA was transferred to nylon membranes (Hybond-N, Amersham) and hybridized overnight at 65 °C in 2 ml hybridization buffer (7.5 × SSC, 50% formamide, 5 × Denhardt's solution, 0.25% SDS, 250 μg ml^{-1} salmon sperm DNA, 5 mM EDTA in 50 mM sodium phosphate, pH 7.2) with a ^{32}P-cRNA mouse BDNF probe (10^7 c.p.m. ml^{-1}). Washing was for 60 min at 60 °C in 0.1 X SSC containing 0.5% SDS. After washing, the blot was incubated for 60 min at room temperature with 0.1 μg ml^{-1} RNase A (Pharmacia) and the film exposed at −70 °C (with intensifying screen) for 48 h. Preparation of the mouse probe: in brief, a mouse brain cDNA library (Clontech) was screened with two independent BDNF oligonucleotides. Double positive clones were isolated and subcloned into the *Eco*RI site of a pBluescript SK^+ vector (Stratagene). The nucleotide sequence corresponding to nucleotides 350–829 of the pig sequence was determined, and a total of only four amino-acid differences (all in the precursor part) were found between mouse and pig BDNF. This indicates a remarkable degree of sequence conservation between pig and mouse BDNF. A single-stranded RNA probe was prepared using this template and T3 polymerase (Promega). The specific activity of this probe was 10^8 c.p.m. μg^{-1}.

and were additive to those of NGF, as previously reported for BDNF[9].

A striking feature of the primary structure of mature BDNF is its similarity to that of NGF: with only three gaps introduced in the NGF sequences to optimize matching, 51 identities are common to the various nerve growth factors (NGFs) (from snake to man) and BDNF (Fig. 2). Significantly, these identities include all six cysteine residues. Although the exact arrangement of the disulfide bridges of BDNF are not yet known, it is clear that such bridges are present (Table 1, legend). Also, the three tryptophan and two phenylalanine residues, as well as most valine and aspartic acid residues, are found at identical positions in NGF.

Most of BDNF's precursor sequence is unrelated to that of NGF, with two exceptions: the putative secretory signal sequence of BDNF shows 5 amino-acid identities (out of 18 amino acids) and a striking overall relatedness with the signal sequence of mouse NGF, where cleavage has been demonstrated to occur after an alanine residue at position 18 (ref. 10). The other similarity with NGF starts at the only N-glycosylation consensus sequence (doubly underlined in Fig. 1), corresponding to asparagine 126. This asparagine is located eight amino acids before the cleavage site giving rise to mature BDNF. The same arrangement is found in several NGFs, as well as the sequence Arg-X-Basic residue-Arg as the last four amino acids of the precursor[11].

To study the site of BDNF synthesis, a mouse cRNA probe was used to probe mouse tissues in northern blot analyses. (Rapid tissue processing for RNA extraction, which is technically difficult with pig tissues, was found to be essential.) A strong signal at a position corresponding to 1.45 kilobases (kb) was detected in the brain (Fig. 3) and spinal cord (data not shown), whereas under identical hybridization conditions, no signal was detected in all other tissue tested including kidney, gut, lung, liver, spleen, heart and skeletal muscle (Fig. 3).

Two main conclusions can be drawn from this study. First, the mRNA coding for BDNF is present in the central nervous system, in areas such as the spinal cord and the superior colliculus that contain the target cells of neurons previously shown to respond to BDNF (primary sensory neurones[9,12] and retinal ganglion cells[7]). These data support the view that BDNF is a target-derived neurotrophic factor. Clearly, detailed studies need to be done to examine the various sites of synthesis of BDNF in the CNS. It is already evident, however, that the distribution of BDNF mRNA is very different from that of NGF mRNA, which is found in many non-CNS tissues[13,14]. It is also apparent that the amounts of BDNF mRNA in the brain are considerably larger than those of NGF mRNA. Second, the amino-acid sequence of mature BDNF shows striking similarity to that of mature NGF, including all six cysteine residues. It is tempting to speculate that BDNF and NGF might also display similarities in their tertiary structures. Their respective neuronal receptors are thus likely to also have common structural features.

There is no reason to think that BDNF and NGF should be the only members of a family of neurotrophic proteins having in common both functional and structural characteristics. Indeed, from a descriptive point of view, a variety of observations suggest that the control of neuronal survival and maintenance of function exerted by target cells both during development and in adulthood is a general phenomenon, and that this control also applies to NGF- and BDNF-independent neurons. Thus it is hoped that the structural features common to both NGF and BDNF can be used to aid the discovery of other members. □

Regulation of Ca^{2+}-dependent K^+-channel activity in tracheal myocytes by phosphorylation

H. Kume, A. Takai*†, H. Tokuno* & T. Tomita*

The Second Department of Internal Medicine and * Department of Physiology, School of Medicine, Nagoya University, Tsurumai-cho 65, Showa-ku, Nagoya 466, Japan

ISOPRENALINE is a β-adrenergic agonist of clinical importance as a remedy for asthma. In airway smooth muscle its relaxant action is accompanied by hyperpolarization of the membrane[1,2] and elevation of the level of intracellular cyclic AMP[3]. Hyperpolarization and relaxation are also induced by drugs such as forskolin, theophylline and dibutyryl cAMP, indicating that cAMP-dependent phosphorylation is involved in producing the electrical response[1]. Cyclic AMP-dependent protein kinase (protein kinase A) has been reported to activate Ca^{2+}-dependent K^+ channels in cultured aortic smooth muscle cells[4] and snail neurons[5,6]. The membrane of tracheal smooth-muscle cells is characterized by a dense distribution of Ca^{2+}-dependent K^+-channels[7]. We have now examined the effect of isoprenaline and protein kinase A on Ca^{2+}-dependent K^+-channels in isolated smooth muscle cells of rabbit trachea, using the patch-clamp technique[8]. Our results show that the open-state probability of Ca^{2+}-dependent K^+-channel of tracheal myocytes is reversibly increased by either extracellular application of isoprenaline or intracellar application of protein kinase A. We also show that this effect is significantly enhanced and prolonged in the presence of a potent protein phosphatase inhibitor, okadaic acid[9–13].

Smooth muscle cells were enzymatically isolated[14] from the trachea of adult male rabbits (2.5–3 kg). The giga-seal method[8] was applied to measure the membrane current under

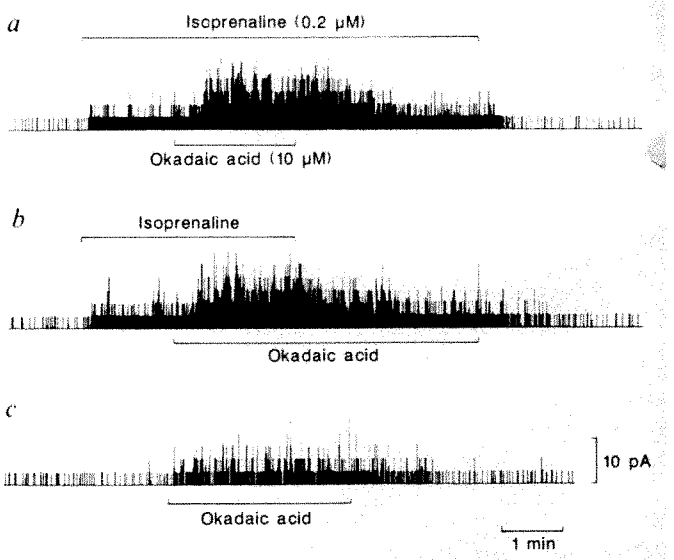

FIG. 1 Effect of isoprenaline on the channel activity and its enhancement by a protein phosphatase inhibitor, okadaic acid. For an explanation of *a*, *b* and *c*, see text. Tracheal smooth muscle cells were dispersed with collagenase and elastase. Continuous recording with a cell-attached pipette filled with a physiological saline of the following composition (mM): NaCl, 127; KCl, 5.9; $CaCl_2$, 2.4; $MgCl_2$, 1.2; dextrose, 11.8 and HEPES, 10 (pH 7.4 at 25 °C adjusted with NaOH). The isolated myocytes were transferred into a small chamber (0.2 ml) which was perfused with physiological saline at 3 ml min^{-1}. Isoprenaline (0.2 μM) and okadaic acid (10 μM) were added to the perfusing solution.

voltage-clamp conditions at room temperature (20–25 °C). Okadaic acid is a polyether derivative of a 38-carbon fatty acid which was first isolated from marine sponges of the genus *Halichondria*[15]. It is a potent inhibitor of protein phosphatases 1 and 2A (PP1 and PP2A)[11,12,16] and produces various effects in physiological systems that are modulated by phosphorylation[9–11,13,17]. For example, okadaic acid has a strong inotropic action on heart muscle[18] that is due to an increase in the open-state probability of Ca^{2+} channels[11], which is thought to be regulated by cAMP-dependent phosphorylation[19]. Okadaic acid has no effect on protein kinases, including protein kinase A[13,17], protein kinase C[20] and Ca^{2+}/calmodulin-dependent myosin light-chain kinase[9]. In smooth muscle tissues, the activities of intracellular PP1 and PP2A are nearly abolished by 10 μM okadaic acid[21].

Figure 1 shows the effect of extracellular application of isoprenaline and okadaic acid on channel activity recorded with a cell-attached pipette. The voltage in the pipette was clamped at −40 mV. Under this condition, the unitary current through the channel was ~3 pA and the open-state probability (P_0; mean ± s.e.m.) was 0.012 ± 0.004 ($n = 3$). Isoprenaline (0.2 μM) increased P_0 to 0.08 ± 0.02 ($n = 3$) (Fig. 1*a*). The P_0 further increased to 0.19 ± 0.08 ($n = 3$) when 10 μM okadaic acid was also applied (Fig. 1*a*). The activating effect of isoprenaline on the channels disappeared within 15–20 s, either by removing isoprenaline (Fig. 1*a*) or by adding 1 μM propranolol to the perfusing solution (results not shown).

The time course for washing out the effect of isoprenaline was markedly prolonged in the presence of 10 μM okadaic acid (Fig. 1*b*). The increased P_0 did not return to the control level until okadaic acid was removed 3 min after the removal of isoprenaline (Fig. 1*b*). The P_0 increased to 0.04 ± 0.01 ($n = 3$) when okadaic acid was applied in the absence of isoprenaline (Fig. 1*c*).

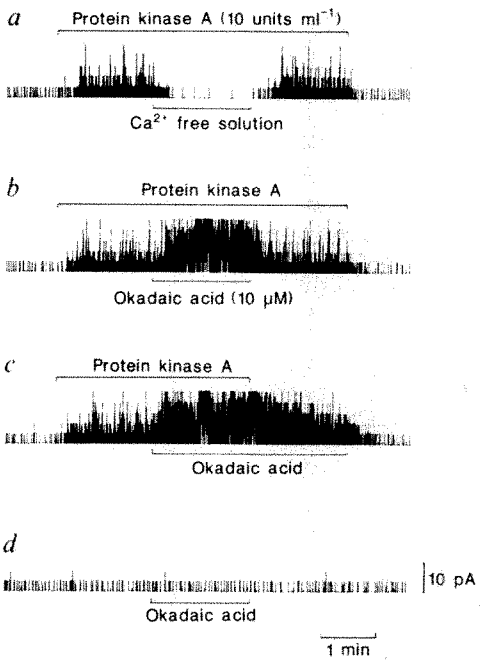

FIG. 2 Effect of protein kinase A on the channel activity and its enhancement by okadaic acid. Continuous recording in an inside-out membrane patch from a tracheal smooth muscle cell at a holing potential of 0 mV. For explanation of *a*–*e*, see text. The pipette filled with physiological saline was attached to the cell membrane, and the response to 0.2 μM isoprenaline shown in Fig. 2 was observed before the membrane was isolated from the cell (not shown). After establishment of the inside-out configuration, the cytoplasmic side of the membrane was perfused with a solution containing (mM): potassium aspartate, 80; KCl, 50; NaCl, 20; $MgCl_2$, 0.8; HEPES, 10; EGTA, 5; ATP-Na_2, 0.3; and cAMP, 0.1 (pH 6.9 at 25 °C, adjusted with NaOH). The free Ca^{2+} concentration was adjusted to 0.1 μM by adding $CaCl_2$. (For the Ca^{2+}-free solution, $CaCl_2$ was not added.) Commerical protein kinase A (Sigma P5511; from bovine heart) was dialysed just before use against the perfusing solution at 0 °C for 4 h to remove buffer materials (such as EDTA, potassium phosphate). Addition of okadaic acid (10 μM) and dialysed protein kinase A (10 units ml^{-1}) had very little effect on the pH of the perfusing solution.

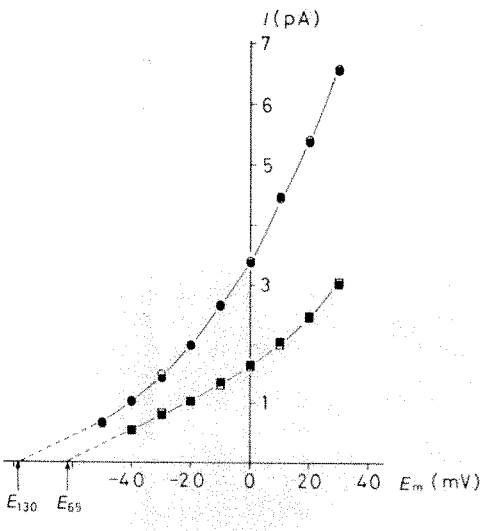

FIG. 3 The *I*–*V* relationship of the channel activated by protein kinase A. In the same type of patch-clamp experiment as illustrated in Fig. 2, the amplitude of the unitary current of the channel (I) was measured at various holding potentials (E_m) using the pipette filled with physiological saline ($[K^+]_o = 5.9$ mM). The K^+ concentration in the bath solution, $[K^+]_i$, was reduced from 130 mM (○ and ●) to 65 mM (□ and ■) by isosmotically replacing K^+ with Na^+. Measurements were made in the absence (open symbols) and presence (closed symbols) of protein kinase A (10 units ml^{-1}) on the cytoplasmic side. The equilibrium potential of K^+ ($=(RT/F)\ln([K^+]_o/[K^+]_i)$) for $[K^+]_i$ of 130 mM and 65 mM are denoted by E_{130} and E_{65}, respectively.

These observations are consistent with the activation of channels by β-adrenergic stimulation that is mediated by phosphorylation of some regulatory protein(s). This possibility was further examined in experiments using isolated inside-out membrane patches (Fig. 2). The cytoplasmic side of the membrane was perfused with a solution containing 0.1 μM free Ca^{2+} and the voltage in the pipette was clamped at 0 mV. The channels were reversibly activated when protein kinase A (10 units/ml^{-1}) was applied to the perfusing solution in the presence of 0.1 mM cAMP and 0.3 mM ATP (Fig. 2*a*). The unitary current of the channels was 3.3 ± 0.1 pA ($n = 10$) and P_0 was 0.008 ± 0.002 ($n = 4$). The P_0 increased to 0.033 ± 0.006 ($n = 4$) ~20 s after application of protein kinase A. Channel opening was almost completely suppressed by perfusing with Ca^{2+}-free solution in the presence of protein kinase A (Fig. 2*a*). The P_0 returned to the control level about 10 s after removal of protein kinase A (Fig. 2*a*), indicating the presence of a relatively high phosphatase activity in the isolated membrane. Indeed, P_0 was increased to 0.23 ± 0.05 ($n = 3$) by adding okadaic acid (10 μM), a protein phosphatase inhibitor, to the perfusing solution in the presence of protein kinase A and 0.1 μM free Ca^{2+} (compare Fig. 1). The activating effect of okadaic acid disappeared quickly when okadaic acid was removed (compare Fig. 1*a*). The time course of disappearance was considerably faster than that observed in Fig. 1*a*, supporting the idea that the site of action of okadaic acid is intracellular. Okadaic acid significantly slowed the recovery from the activating effect of protein kinase A. (Fig. 2*c*; compare Fig. 1*b*). In excised patches, okadaic acid (10 μM) failed to produce any effect on channel activity when it was applied in the absence of protein kinase A (Fig. 2*d*; compare Fig. 1*c*).

Similar results were obtained when the catalytic subunit of protein kinase A (Sigma P2645; 10 units ml^{-1}) was used instead of the holoenzyme and cAMP. Neither the holoenzyme nor the

catalytic subunit produced any effect on channel activity in the absence of ATP (data not shown).

Figure 3 shows the voltage–current (V–I) relationship for the channel activated by protein kinase A. In an inside-out patch, the unitary current of the channel (I) was measured at various holding potentials (E_m). The concentration of K^+ in the pipette ($[K^+]_0$) was 5.9 mM. When the K^+ concentration in the bath ($[K^+]_i$) was 130 mM, the maximal slope conductance of 120 pS was obtained in the voltage range 20–30 mV (Fig. 3). In myocytes of the rabbit portal vein, two types of Ca^{2+}-dependent K^+-channels have been identified with either a large or small conductance (K_L type and K_S type)[22]. The V–I relationship for the channels observed in the present experiments was similar to that for the K_L-type K^+-channel. The V–I curve shifted to the right and the curvature decreased as $[K^+]_i$ was reduced. The maximal-slope conductance was 55 pS when $[K^+]_i$ was 65 mM (Fig. 3). The reversal potentials estimated for $[K^+]_i$ of 130 mM and 65 mM by extrapolation of the V–I curves to the abscissa, agreed well with the equilibrium potentials of K^+ (E_{130} and E_{65}). Thus, channels activated by protein kinase A observed in these experiments belong to the category of Ca^{2+}-activated K^+-channels (see also Fig. 2*a*). The V–I relationship was not affected by protein kinase A (Fig. 3) or okadaic acid.

These results strongly support the idea that isoprenaline activates Ca^{2+}-dependent K^+-channels in tracheal myocytes by phosphorylation of a channel- or channel-related protein(s). In isolated membranes, okadaic acid increased the open-state probability of the channels in the presence of protein kinase A activity, whereas it failed to produce any effect when protein kinase A was not added to the perfusing solution (see Fig. 2). This indicates that some protein phosphatase activity is bound to the membrane, whereas the kinase activity is present only in the cytosol. In intact myocytes, okadaic acid caused a slight but clear elevation of the P_0 in the absence of isoprenaline (see Fig. 1*c*). Therefore, some kinase activity seems to remain even under conditions of no stimulation.

Until now the clinically important relaxant action of isoprenaline on airway smooth muscle has been thought to be due to a cAMP-dependent increase in sequestration of intracellular Ca^{2+} and/or Ca^{2+} extrusion from the cell[23,24]. Because an increase of K^+ conductance results in hyperpolarization, the cAMP-mediated activation of the Ca^{2+}-dependent K^+-channels, which are densely distributed in the plasma membrane of trachael myocytes[7], may be another important factor in the relaxant effect of isoprenaline. □

Bidirectional movement of actin filaments along tracks of myosin heads

Yoko Yano Toyoshima*, Chikashi Toyoshima* & James A. Spudich†

Department of Cell Biology, Stanford University School of Medicine, Stanford, California 94305, USA

IT is well established that muscle contraction results from the relative sliding of actin and myosin filaments. Both filaments have definite polarities and well-ordered structures. Thick filaments, however, are not vital for supporting movement *in vitro*[1–4]. Previously we have demonstrated that actin filaments can move continuously on myosin fragments (subfragment-1 or heavy meromyosin (HMM)) that are bound to a nitrocellulose surface[3]. Here we report that actin filaments can move in opposite directions on tracks of myosin heads formed when actin filaments decorated with HMM are placed on a nitrocellulose surface. The actin filaments always move forward, frequently changing the direction of the movement, but never move backward reversing the polarity of the movement. The direction of movement is therefore determined by the polarity of the actin filament. These results indicate that myosin heads have considerable flexibility.

Decorated actin filaments were formed by mixing HMM and actin filaments labelled with rhodamine-phalloidin at an HMM:actin molar ratio of slightly less than 1:2. The solution was diluted 20 times and applied to a flow cell. A solution of HMM alone, applied at this concentration (5 μg ml^{-1}) and randomly distributed over the nitrocellulose surface, was too dilute to support movement (Toyoshima *et al.*, manuscript in preparation). The decorated actin filaments bound to the nitrocellulose surface showed the characteristic arrowhead pattern indicative of a unipolar arrangement of myosin heads along the actin filaments[5,6] (Fig. 3*a*).

On addition of ATP, actin filaments started to move. In Fig. 1, initial positions of actin filaments are shown in red, thus indicating the tracks of HMM; moving filaments appear in white (the part of the actin filament on the HMM tracks) or blue (the part that has run off the HMM tracks). After the actin filaments moved one filament length at a constant speed, they came off the surface and showed only Brownian motion (Fig. 1*a*). This result demonstrates that the inertia of the filament was negligible, as was expected for movement in a low-Reynolds-number fluid. During the following minutes, some of the actin filaments released from HMM tracks elsewhere in the flow cell came to the surface again by diffusion and repeated the movement: they followed exactly the same tracks, and came off at the end of the tracks. Surprisingly, some filaments moved in the opposite direction to that of the initial filaments. Occasionally an actin filament moved to one end of the track and came off, then flipped over and moved towards the other end of the same track. Sometimes two actin filaments passed over each other on a track (Fig. 1*b*). The speed of the movement was about the same in either direction and independent of the filament length. These observations indicate that the direction of the movement is simply determined by the polarity of actin filaments and that the HMM is flexible enough to support the movement in any direction along the surface.

The density of HMM and the width of the track were examined before and after the addition of ATP by using immunogold labelling. The primary antibody used had a very high affinity for the 25K–50K junction of myosin heads, and the secondary antibody was conjugated with gold. Figure 2*a* shows a fluores-

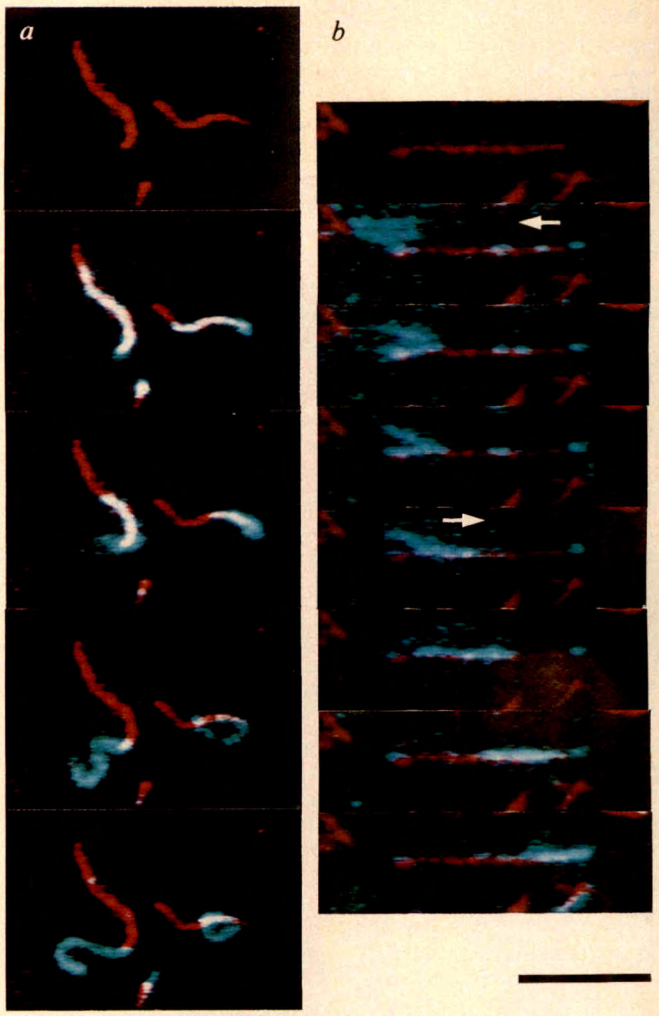

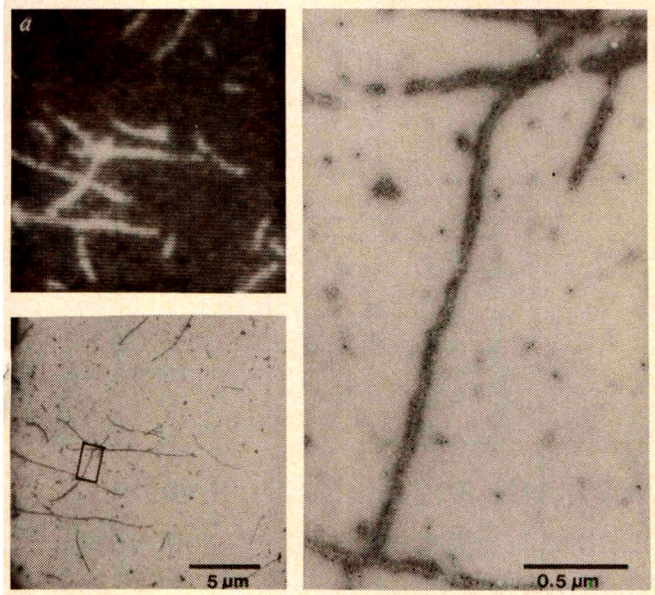

FIG. 1 Sequences of video-processed images showing the movement of actin filaments along tracks of HMM. Locations of initial actin filaments decorated with HMM to form the HMM tracks were recorded before ATP addition; they are shown in red and superimposed on real-time images shown in blue. As a result, the part of the filament on the HMM track appears white. *a*, Immediately after the addition of ATP. Filaments moved one filament length and came off the surface (or sometimes remained attached at their trailing ends, possibly due to radiation damage) and exhibited Brownian motion. Sequence, 0.5 s between frames. *b*, Actin filaments following the same track in opposite directions (arrows). In the minutes following addition of ATP, actin filaments released from HMM tracks elsewhere came to the surface again by diffusion and followed the same tracks. In this example, two filaments moved on the track from left to right while one short filament moved from right to left. Sequence, 0.5 s between frames; scale bar, 10 μm.

METHODS. Protein preparations, assay conditions and the optics system have been described previously[3,14]. Chymotryptic HMM (100 μg ml^{-1}) was mixed with rhodamine-phalloidin-labelled actin filaments (28 μg ml^{-1}) at slightly less than stoichiometric amounts in the assay buffer (25 mM KCl, 4 mM $MgCl_2$, 1 mM dithiothreitol, 25 mM imidazole, pH 7.4) to form rigor complexes. The mixture was applied to a flow cell at an actin concentration of 1.4 μg ml^{-1} and allowed to bind to the surface for 30 s. BSA (0.5 mg ml^{-1}) in assay buffer was applied to wash unbound materials away and to block the free surface from non-specific protein binding. ATP (1 mM) in assay buffer was perfused through the flow cell to start the movement of the actin filaments. Fluorescence images were processed (averaging, linear contrast enhancement and superimposition) with a video-image processor (series 151, Imaging Technology) controlled by a microcomputer (IBM PC/AT).

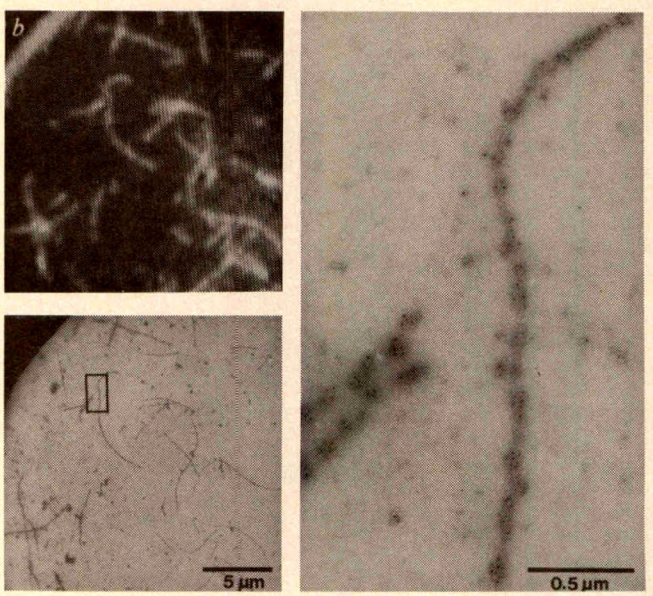

FIG. 2 Fluorescence images of actin filaments decorated with HMM and electron micrographs of the same fields. Fluorescence images (upper left) were recorded before ATP addition. Electron microscopic images of the same fields (lower left) were recorded before (*a*) or after (*b*) ATP addition; higher magnification images of boxed-off areas (right) show immunogold labelling of HMM. Note that the appearance of the HMM tracks (for example width and density of HMM) seemed to be unaltered by the movement of actin filaments. Scale bars, 5 μm (left) and 0.5 μm (right).

METHODS. To observe an identical field by both fluorescence and electron microscopy, an electron microscope finder grid (HF 7, Graticule, UK) was sandwiched between a coverslip and the nitrocellulose film that constituted the top part of the flow cell. Fluorescence images of actin filaments on marked grid squares were recorded first. Either before or after the addition of ATP, antibody against myosin subfragment-1 (25K–50K junction) was applied to the flow cell and incubated for 40 min. Unbound antibody was washed away with 0.5 mg ml^{-1} bovine serum albumin, and secondary antibody conjugated with gold (AuroProbe EM, Janssen, Belgium) was applied. After 40 min of the incubation and washing, the grid was picked up from the coverslip and negatively stained with 1% uranyl acetate. Electron microscope pictures of the marked grid squares were taken in an electron microscope 400T (Philips) at ×10,000 and ×33,000 magnification.

cence image of decorated actin filaments before ATP addition, and electron micrographs of the corresponding field. Filaments were well preserved and remained at the same locations despite the incubation with antibodies and the negative staining. More than 99% of the filaments were identified in both images (left). At a higher magnification (right), gold patches were seen to align along the actin filaments. The density of gold particles in the background reflects a random distribution of HMM which was not of sufficient density to support actin filament movement. Figure 2*b* shows a fluorescence image before ATP addition, and electron micrographs of the corresponding area after actin filaments had moved off the tracks in the presence of ATP. Gold particles still remained along the initial tracks of decorated filaments (right). The width of the track or the density of gold particles in the background did not increase appreciably. Furthermore, the density of the gold particles along the tracks remained almost the same (31.1 ± 2.8 particles per μm, $n = 20$ filaments, before ATP addition; 30.6 ± 3.4 particles per μm, $n = 23$, after ATP addition). These observations indicate that the HMM molecules associated with the nitrocellulose surface while maintaining unipolar binding to actin filaments, and stayed attached to the surface, probably in their original locations, even after actin filaments moved away.

To examine the flexibility of the nitrocellulose-bound HMM in binding to actin filaments, tracks of HMM were formed using long actin filaments, which were subsequently removed by ATP addition, and then very short actin filaments prepared with severin[7] were introduced in the absence of ATP. If HMM could bind to actin filaments lying in either direction along the track, then it was anticipated that we should be able to see arrowhead patterns pointing in opposite directions on a single track of HMM. Figure 3*b* shows several short repeats of arrowheads formed on a long track; they indeed show opposite polarities (see long arrows). Immunogold labelling of severin (Fig. 3, short arrows), which binds to the barbed end of actin filaments[8], corroborates the polarity.

These experiments show that (1) actin filaments can follow the path pre-determined by HMM locations irrespective of the filament length, (2) actin filaments can move along the same HMM track in opposite directions, and (3) HMM bound to a nitrocellulose surface is flexible and can form a rigor complex even with an actin filament having opposite polarity to that of the initial filament. Two earlier observations showed that there is considerable flexibility in the HMM portion of the myosin molecule. First, two heads of HMM bind to actin molecules on the same strand in the absence of ATP[9], showing that the two heads are translationally related in this bound configuration. Second, a single IgG molecule sometimes cross-links two heads of myosin[10,11], showing that the two heads can be arranged so that the same epitopes on the two heads face each other. Thus, there must be a considerable rotational freedom in the head-rod junction or head itself. The head–rod junction is known to have a large degree of freedom (for example, ref. 12); the myosin head may be rotating rapidly around its long axis looking for the correct binding site on the actin. One possible interpretation for the bidirectional movement described here is, therefore, that 180° rotational freedom exists in HMM. This interpretation is strongly supported by the complementary experiments reported by Reedy *et al.*[13]. They showed that myosin heads tethered in a single thick-filament of a mutated *Drosophila* muscle sarcomere can bind with opposite rigor-cross-bridge angles to flanking thin filaments, which are apparently of opposite polarities. □

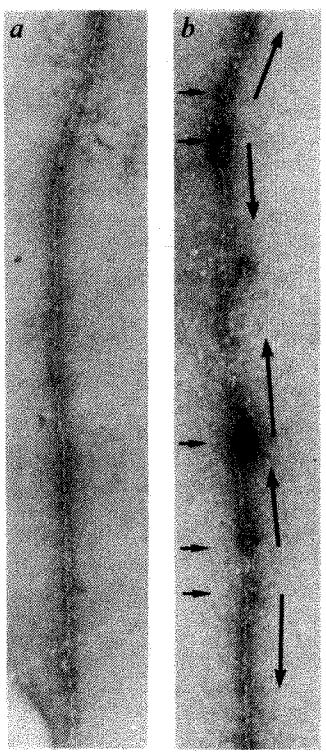

FIG. 3 *a*, Negatively stained actin filament decorated with HMM on a nitrocellulose film of a flow cell; well-ordered arrowhead patterns show unipolar binding of HMM along the actin filament. *b*, Short decorated actin filaments pointing in opposite directions (long arrows) on a single long track of HMM, showing that the HMM bound to the nitrocellulose film could bind to actin filaments with either polarity. HMM tracks were first formed by placing onto the nitrocellulose long decorated actin filaments, which were removed later by addition of ATP; short actin filaments prepared with severin were then introduced in the absence of ATP to form rigor complexes with the HMM on the track. The gold particles (short arrows) show the presence of severin at the barbed ends of the short actin filaments, corroborating the polarity indicated by the arrowhead pattern. Scale bar, 0.2 μm.

METHODS. Short actin filaments were prepared with severin, an actin-filament severing protein[7]. Severin was first mixed with actin labelled with rhodamine-phalloidin at a 1:100 molar ratio in the absence of Ca^{2+}; 0.1 mM Ca^{2+} was subsequently added to the mixture to activate the severin[7]. Antibody against severin and gold-conjugated secondary antibody were applied after introduction of the actin filaments into a flow cell, and the specimens were negatively stained with 1% uranyl acetate.

Segment-specific expression of a homoeobox-containing gene in the mouse hindbrain

Paula Murphy, Duncan R. Davidson & Robert E. Hill

MRC Human Genetics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU, UK

THE process of segmentation, in which the developing embryo is divided into repetitive structures along its antero–posterior (A–P) axis, as a means of organizing and coordinating the body plan is found in a wide range of organisms. In *Drosophila*, homoeotic genes are involved in all levels of segmental organization and in determining segment identity[1]. The roles of these genes in segmentation have been found mainly by mutational studies[2,3], but also by *in situ* hybridization, which has shown their domains of expression. In contrast to *Drosophila*, however, embryonic

expression of homoeobox-containing genes in vertebrate organisms has not been found to follow a segmental pattern[4]. Vertebrate segmentation can be clearly seen in the mesodermal somites, but repetitive morphological structures in the central nervous system (neuromeres)[5–13] have only recently been shown to have developmental significance. Neuromeres in the hindbrain (rhombomeres) have been defined as segmental units by their pattern of nerve formation in the developing chick[14] and by the alternating expression of *Krox-20*, a gene encoding a zinc-finger DNA-binding protein, in the 9.5-day-old mouse[15]. Here we report that a mouse homoeobox-containing gene, *Hox-2.9*, is expressed in a segment-specific manner in the developing mouse hindbrain. This expression is in a region which is flanked by the regions of expression of *Krox-20*, and is precisely contained within a single neuromere, rhombomere 4.

A homoeobox-containing gene mapping to the *Hox-2* gene cluster on chromosome 11 (refs 16 and 17), which we have characterized as *Hox-2.9* (P.M. *et al.*, manuscript in preparation; R. Krumlauf, personal communication), was isolated from an 8.5-day-old mouse embryonic complementary DNA library. We determined the pattern of *Hox-2.9* expression during development by *in situ* hybridization using a probe specific for *Hox-2.9*, 3′ to the homoeobox, and analysing serial sections from 6.5-day-, 8.5-day-, 9.5-day-, 10-day- and 13.5-day-old embryos, using at least four embryos from each stage.

Hox-2.9 transcripts were not detected in the 6.5-day-old embryo, when gastrulation begins. At 8.5 days of development the embryo is at the neural fold stage. At this stage, expression of *Hox-2.9* is detected in both the neural ectoderm and the underlying mesoderm (Fig. 1*a*, *b*). The domain of expression is extensive, with an anterior limit in the developing hindbrain posterior to the preotic sulcus (Fig. 1*c*, *d*). The low level of expression and the absence of morphological markers in the hindbrain, however, made it difficult to locate the anterior limit of expression more precisely. Mesodermal expression was restricted to lateral and presomitic mesoderm; no label was detectable in the somites.

By 9.5 days the expression pattern had changed dramatically, as had the complexity of the embryo. At this stage the segmental units of the hindbrain, the rhombomeres, could easily be seen as a series of neuroepithelial swellings in frontal and parasagittal sections (Figs 2 and 3*d*). Individual rhombomeres could be

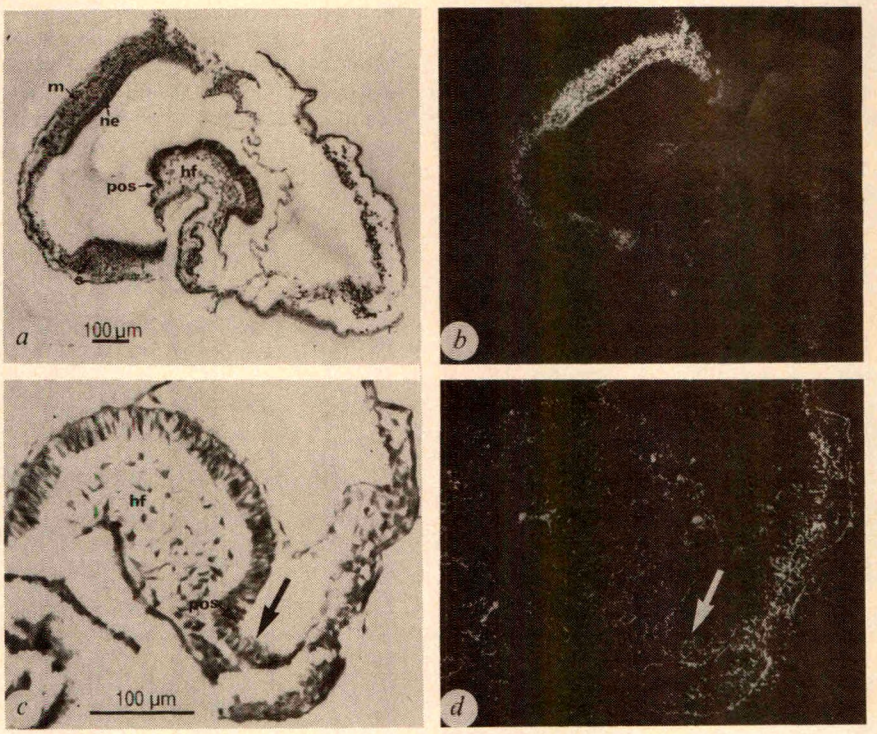

FIG. 1 *In situ* hybridization of a ^{35}S-labelled antisense probe for *Hox-2.9* to 8.5-day-old mouse-embryo sections. *a*, *b*, Sagittal section showing expression in the mesoderm (m) and neural ectoderm (ne). *c*, *d*, Sagittal section through the headfold (hf) region showing the anterior limit of expression in the neuroectoderm and lateral mesoderm (arrow). *a* and *c*, Brightfield photographs; *b* and *d* are the corresponding darkfield photographs. s, Somite; pos, preotic sulcus.
METHODS. The *in situ* hybridization procedure used was as previously described[31], with ~4 × 10^5 d.p.m. of ^{35}S-labelled UTP incorporated into RNA applied per section. Sense-strand control probe was included routinely and showed no hybridization signal above background (data not shown).

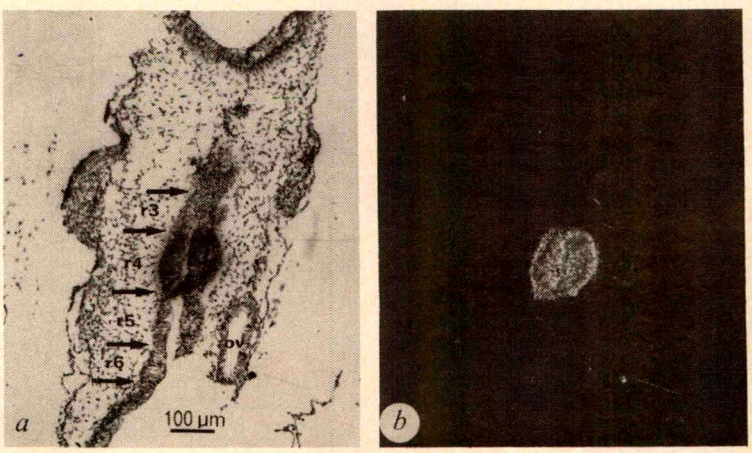

FIG. 2 Frontal section through the hindbrain of a 9.5-day-old embryo showing localized expression of *Hox-2.9* within rhombomere 4 (r4). *a*, Brightfield photograph. *b*, Corresponding darkfield photograph. ov, Otic vesicle; arrows indicate neuromere boundaries; rhombomeres are numbered r3, r4, r5, r6.

identified visually by their position relative to the otic vesicle and numbered as shown in Fig. 4. In the hindbrain, *Hox-2.9* was expressed at this stage in a single segment, rhombomere 4. It was difficult, however, to relate rhombomere 4 to the hindbrain expression at day 8.5, when rhombomeres are not morphologically detectable. Expression was detected throughout rhombomere 4, with the exception of the thin roof plate. The boundaries of expression corresponded precisely with the morphological boundaries of rhombomere 4 (Figs 2 and 3*d*), and Fig. 3*c* shows the precision of this boundary at the cellular level. Rhombomere 4 seems to be the principal site of expression of *Hox-2.9*, because the very localized signal seen at this site was consistently much higher than any other signal detected.

Outside the hindbrain the anterior neural tube was unlabelled at 9.5 days, but expression was detected in the neural tube posterior to the forelimb buds (Figs 3*a*, *b*). Expression was still detected in the presomitic mesoderm but not in the somites (Figs 3*e*, *f*). Gut-associated mesenchyme and the epithelium of the upper gut posterior to the third branchial arch were also labelled (Fig. 3*a*, *b*), the gut-associated mesenchyme having been derived from lateral-plate mesoderm, which showed expression at day 8.5. A low level of expression was detected in the nephrogenic duct (Fig. 3*a*, *b*). Analysis of sections through 10-day-old embryos showed no further change in *Hox-2.9* expression. Unlike most homoeobox-containing genes previously analysed, the expression of *Hox-2.9* did not persist in the late embryo stage: at 13.5 days of development, expression could not be detected in any part of the embryo by examination of serial sections in sagittal, transverse or frontal planes. Neuromeric boundaries could also no longer be seen at this stage.

The expression of *Hox-2.9* in rhombomere 4 indicates that this gene plays a part in the formation or differentiation of this segment. Neuromeres have segmental identities, as seen by the exit points of cranial ganglia from specific neuromeres[14] with the facial and acoustic ganglia extending from rhombomere 4. Independent evidence for the genetic control of development within this neuromere comes from the phentotype of the mouse developmental mutant *kreisler*, which displays faulty segmentation of the hindbrain and specific degeneration of the cells of rhombomere 4 by day 9.5 (ref. 18). The mutation maps to mouse chromosome 2 (ref. 19) and is therefore not allelic with *Hox-2.9*. It is possible that *Hox-2.9* and *kreisler* are both genetic regulators of segmentation in the hindbrain. We can now investigate the relationship between these two genes.

Krox-20 is expressed in rhombomeres 3 and 5 (ref. 15), which flank the region of expression of *Hox-2.9* at day 9.5. At day 8.5, before the neuromeres become visible, *Krox-20* expression is first detected in the region of two neuroepithelial invaginations, proneuromeres-A and -B, indicating that segments start to become established at this stage[15]. *Krox-20* is therefore a likely candidate for involvement in the process of segmentation because its expression precedes the appearance of morphological segments. The spatial and temporal correlation between the expression of *Hox-2.9* and *Krox-20* raises the possibility that their products interact, directly or indirectly, in the process of segmentation in this region of the central nervous system (CNS). Both of these genes are thought to encode regulatory proteins on the basis of the DNA-binding motifs that the proteins possess: *Hox-2.9* encodes a protein that has a helix-turn-helix motif[20] and *Krox-20* encodes a protein with a zinc-finger DNA-binding

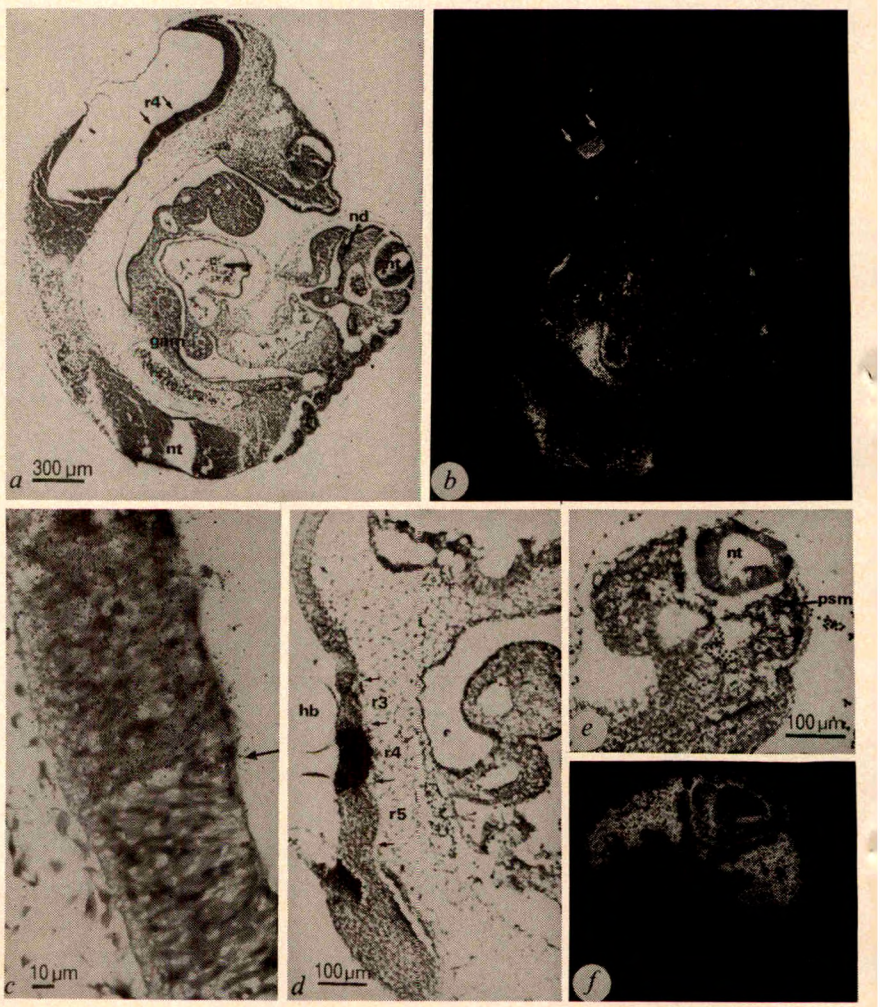

FIG. 3 Expression of *Hox-2.9* in 9.5–10-day-old mouse embryos. *a*, *b*, Sagittal section of a 10-day-old embryo showing expression in the hindbrain (r4, rhombomere 4), the gut-associated mesenchyme (gam), the nephrogenic duct (nd), and the posterior neural tube (nt). *c*, Boundary between r3 and r4 (marked with arrow) in a 10-day sagittal section showing expression of *Hox-2.9* within r4. The short autoradiographic exposure time (two weeks) allowed the labelling of individual cells to be observed and emphasized the sharpness of this expression boundary. *d*, Sagittal 9.5-day embryo section probed with the *Hox-2.9*-specific probe and exposed for a long period (5 weeks) shows the morphology of the hindbrain and the expression of *Hox-2.9* in r4. hb, Hindbrain. *e*, *f*, Transverse section showing expression of *Hox-2.9* in presomitic mesoderm (psm) and the neural tube (nt) in posterior regions of the 9.5-day-old embryo. *a* and *e*, Bright field photographs. *b*, *f*, Corresponding darkfield photographs.

motif[21,22]. There is evidence of interaction between proteins with these regulatory domains within the *Drosophila* segmentation system[23].

An evolutionary relationship has been suggested between genes of the *Hox-2* and *Hox-1* clusters in the mouse and the homoeotic genes of the Antennapedia complex in *Drosophila*[16,17]. The sequence of the *Hox-2.9* homoeobox (data not shown) shows a high degree of similarity to *Hox-1.6*, which is most similar to the *Drosophila* gene *labial*[24]. It is of interest that both *Hox 2.9* and *Hox 1.6* have the same temporal pattern of expression[25] (P.M. *et al.*, manuscript in preparation). *Labial* has a homoeotic role in determining segmental identity and its pattern of expression marks a single ancestral segment in the developing *Drosophila* head[26,27]. Most evidence suggests that segmentation arose independently in invertebrates and vertebrates[28]; the expression of *labial* and *Hox-2.9* in single segments may reflect parallels in the mechanisms that determine the identity of anterior segments in invertebrates and vertebrates.

The results presented here raise the possibility that other homoeobox-containing genes are involved in specifying neural segments. Numerous expression studies on mouse homoeobox-containing genes show that their transcripts are most abundant within the developing CNS, where they occupy large overlapping domains[4]. Several of these transcripts have anterior boundaries to their expression in the hindbrain[16], and our work indicates that studies should now be undertaken to identify these boundaries in sections where neuromeres are well defined. The distinct anterior limit of *Hox-1.5* expression lies at a neuromere boundary[29]. We infer, from its position rostral to the otic vesicle[30], that this boundary lies between rhombomeres 4 and 5, which coincides with the posterior limit of *Hox-2.9* expression.

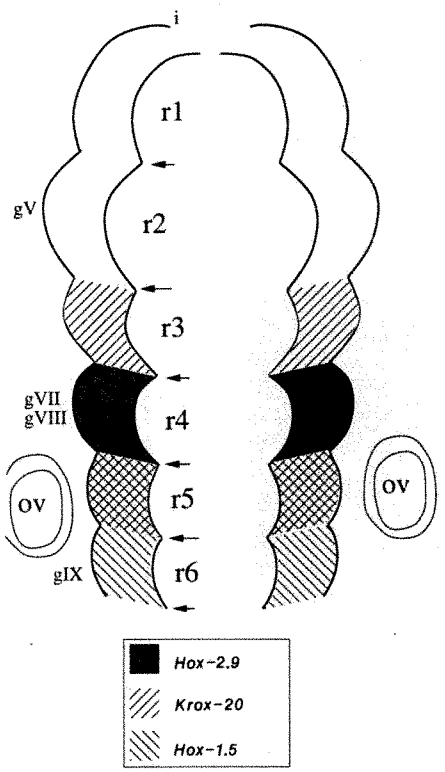

FIG. 4 Diagrammatic representation of a frontal section through the hindbrain of a 9.5-day mouse embryo showing the position of the neuromeres (rhombomeres) with respect to the otic vesicle (ov), the hindbrain–midbrain junction (isthmus, i), and the cranial ganglia which are represented alongside the rhombomeres from which they extend (gV–gIX). The arrows indicate rhombomere boundaries, and the rhombomeres are numbered from anterior to posterior (r1–r6). The shaded areas indicate the domains of expression of *Hox-2.9*, *Hox 1.5* and *Krox-20* in the hindbrain (see text for refs). *Hox-1.5* expression extends posteriorly into the neural tube.

It has been suggested that the overlapping domains of homoeobox-containing-gene expression convey positional information in the form of unique combinations of gene products in blocks along the A–P axis[4]. It remains to be seen if these blocks relate to neuromeres. In this context, *Hox-2.9* is unique in being expressed within a single neuromere, and its expression within rhombomere 4 indicates that it is involved in specifying the unique identity of this segment. □

CD3-negative natural killer cells express ζ TCR as part of a novel molecular complex

Paul Anderson*†, Michael Caligiuri*, Jerome Ritz* & Stuart F. Schlossman*

* Division of Tumor Immunology, Dana-Farber Cancer Institute, 44 Binney Street, Boston, Massachusetts 02115, USA
† Department of Rheumatology and Immunology, Brigham and Women's Hospital, Harvard Medical School, 75 Francis Street, Boston, Massachusetts 02115, USA

NATURAL killer (NK) cells are large granular lymphocytes capable of killing tumour cells in a non-MHC restricted manner[1,2]. NK cells do not express cell-surface CD3, or any known target recognition structure analogous to the T cell antigen receptor (TCR) heterodimers ($\alpha\beta$ or $\gamma\delta$)[3–8]. Consistent with their lack of expression of a CD3–TCR complex, NK cells do not require prior sensitization or antigen presentation by accessory cells to specifically recognize their tumour targets[1]. Although NK cells do not express CD3–TCR, they do express CD2, the target of an alternative activation pathway which is functional in both T cells and NK cells[9–12]. In T cells, this alternative activation pathway utilizes some component of the CD3–TCR complex as a transducer molecule that is required for mitogenesis[13–15]. The fact that NK cells are activated by this alternative pathway suggested that they might express a related subunit of the CD3–TCR complex capable

of transducing the CD2-mediated signal. Here we show that human NK cells express the ζ-chain of the TCR complex in association with additional structures not included in CD3–TCR.

Total cellular RNA extracted from clonal and polyclonal populations of human peripheral blood NK cells was probed for its expression of ζ TCR messenger RNA by northern blotting (Fig. 1, top). Compared with $CD3^+$ T cells (lane 1), both the clonal (JJ1, lane 2) and polyclonal (lane 3) NK populations expressed significant amounts of ζ-chain message. By contrast, neither the JJ1 NK clone, nor the polyclonal population of peripheral blood $CD3^-$ NK cells expressed detectable amounts of CD3 γ mRNA (Fig. 1, middle). As previously reported[7], both NK populations expressed small amounts of CD3 ε mRNA (Fig. 1, bottom panel). These results suggested that one or both of these TCR subunits might participate in a novel NK cell receptor complex.

To determine whether either of these mRNAs was translated into a stably expressed protein product, we screened two $CD3^-$ peripheral blood NK cell clones for their expression of CD3 ε CD2, ζ TCR and CD56 (NKH1) by flow cytometry. Figure 2 shows the flow cytometry phenotype of two $CD3^-$ NK clones that have been described previously[1]. Both clones were found to be $CD3^-$, $CD2^+$, ζ TCR^+ and $NKH1^+$. The presence of ζ TCR in clonal and polyclonal populations of $CD3^-$ NK cells was confirmed by the immunoblotting analysis shown in Fig. 3. Detergent lysates prepared from T cells (lane 1), NK clones JJ1 and JT_B18 (lanes 2 and 3) and interleukin-2 (IL-2) expanded peripheral blood $CD3^-$ NK cells (lane 4) all expressed significant amounts of ζ TCR migrating as a single band with a

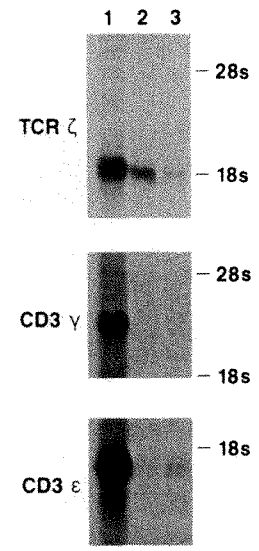

FIG. 1 Northern blot analysis of T cells and NK cells. Lanes 1, 2, and 3 contain RNA extracted from a $CD4^+$ T-cell clone (T4Cl), an NK clone (JJ1) and peripheral blood $CD3^-$ NK cells, respectively. Nitrocellulose blots were probed with complementary DNA inserts encoding ζ TCR (top), CD3 γ (middle) and CD3 ε (bottom) as described below.

METHODS. Cellular RNA was extracted[23] from a $CD4^+$ T-cell clone (T4Cl), an NK clone (JJ1), and peripheral-blood NK cells prepared in the following manner. Peripheral blood lymphocytes were isolated from whole blood by centrifugation over Ficoll Hypaque. T lymphocytes were depleted by antibody-mediated complement lysis using a monoclonal antibody reactive with CD6. The remaining cells were cultured in the presence of recombinant IL-2 (1,000 U ml^{-1}) for 14 days. Viable cells were collected by centrifugation over Ficoll Hypaque and further depleted of cells expressing CD3 using magnetic beads coupled to anti-CD3 antibody. The resulting population was phenotypically <1% $CD3^+$ and 89% $NKH1^+$, and demonstrated non-MHC restricted killing of tumour targets as previously described[24]. RNA from $CD3^+$ T cells (5 μg poly(A)$^+$ RNA, lane 1), the JJ1 NK clone (20 μg total cellular RNA, lane 2), and polyclonal $CD3^-$ NK cells (20 μg total cellular RNA, lane 3), was separated on a 1.2% formaldehyde agarose gel, transferred to nitrocellulose and probed for the expression of the indicated mRNAs. A full length cDNA encoding the human TCR ζ-chain in the vector pGEM3 was a gift from A. Weissman[25]. Insert DNA was excised using appropriate restriction endonucleases, separated on a 1% low melt agarose gel, and extracted with phenol. Insert DNA was labelled with ^{32}P by nick translation and hybridized to the nitrocellulose blot described above. The nitrocellulose blot hybridized to ζ TCR was stripped and rehybridized using cDNA probes encoding CD3 γ (ref. 26) and CD3 ε (ref. 27), both gifts from C. Terhorst. The CD3 γ mRNA is detected as a 3.5 kilobase (kb) transcript and the CD3 ε mRNA is detected as a 1.8 kb transcript. The relative migration of 28S and 18S ribosomal RNAs are indicated.

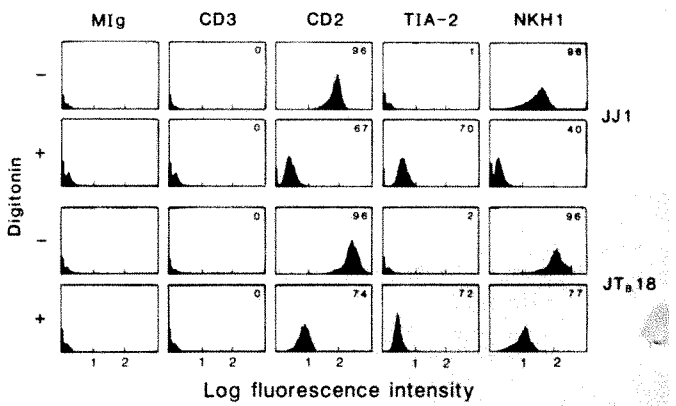

FIG. 2 Flow cytometric analysis of permeabilized and unpermeabilized NK clones.

METHODS. Clonal populations of peripheral blood NK cells were isolated as described[28]. These cells were capable of non-MHC restricted cytotoxicity against a variety of tumour targets as has been reported[1,28]. Clones designated JJ1 and JT_B18 were stained with control ascites (MIg), monoclonal antibodies reactive with CD2 (ref. 9) (1 old 24Cl, immunoglobulin (Ig)G2), CD3 ε (refs 29, 30) (RW24B6, IgG2), ζ TCR (ref. 20) (TIA-2, IgG1) or NKH1 (ref. 31) (IgG1), and analysed by flow cytometry. Both clones were stained in the absence or presence of digitonin, a permeabilization agent that allows the detection of intracellular targets by exogenously added antibody[32]. The monoclonal antibody reactive with ζ TCR (TIA-2) has been shown to stain permeabilized, but not unpermeabilized T cells, suggesting that it recognizes an intracellular epitope of this antigen receptor subunit[20]. Individual histograms are derived from analysis of 10,000 individual cells. Numbers in the upper right-hand corner of each histogram give the percentage of positively staining cells.

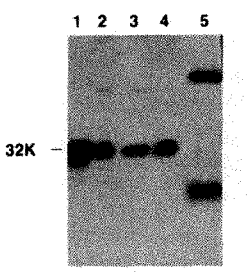

FIG. 3 Immunoblotting analysis using a monoclonal antibody reactive with ζ TCR (TIA-2). Lane 1, Peripheral blood T lymphocytes; Lane 2, NK clone JJ1; Lane 3, NK clone JT_B18; Lane 4, peripheral blood NK cells; Lane 5, 1 μg of IgG1 antibody treated with 2-mercaptoethanol. Heavy and light chains are visualized by virtue of their reactivity with the rabbit anti-mouse developing reagent and serve as size markers.

METHODS. The indicated cell types (5×10^6 cells per sample) were solubilized in NP-40 lysis buffer (1% NP-40, 150 mM NaCl, 1 mM EDTA, 1 mM PMSF, 50 mM Tris, pH 8.0) for 30 min on ice, then centrifuged for 30 min at 12,000g. Supernatants were diluted 1:1 with sample buffer (2% SDS, 10% glycerol, 0.1 M Tris HCl, pH 6.8, 0.02% bromphenol blue), separated on 10% SDS polyacrylamide gels, transferred to nitrocellulose, and probed with TIA-2 as previously described[20].

relative molecular mass (M_r) of 32,000 (32K). In some immunoblots, ζ TCR migrated as a doublet with the upper band at 32K. The relative expression of ζ TCR in $CD3^+$ T cells and NK cells was estimated from both northern analysis (normalized to the relative expression of actin mRNA, not shown) and immunoblotting analysis (Fig. 3) to be ~2:1. These results indicate that ζ-chain expression is not limited to cells possessing the entire CD3-TCR complex.

In T cells, the ζ-chain appears to regulate signal transduction mediated by the antigen-receptor heterodimer[16-19]. If it has a similar function in NK cells, its presence might explain the differential responsiveness of T cells and NK cells to CD2 mediated activation in the absence of cell-surface CD3. By comparing the ζ TCR-containing complexes immunoprecipitated from digitonin lysates prepared from T cells to those immunoprecipitated from lysates prepared from NK cells, we hoped to identify candidate NK receptor complexes that might be functionally analogous to the T-cell-antigen-recognition unit. Digitonin-solubilized cells were immunoprecipitated with antibodies reactive with either CD3 ε or ζ TCR, and analysed on non-reducing/reducing diagonal gels as shown in Fig. 4. As we have previously reported[20], peripheral blood T lymphocytes express a receptor complex composed of an $\alpha\beta$ heterodimer, the CD3 molecular complex (γ, δ and ε), and ζ (Fig. 4*a*). The receptor complexes immunoprecipitated by anti-CD3 ε and ζ TCR antibodies differed in two ways. First, ζ TCR immunoprecipitates included a 60-70K spot above the diagonal that was less prominent in CD3 ε immunoprecipitates. Second, ζ TCR immunoprecipitates included a novel heterodimer composed of ζ and a 12K structure that was not seen in CD3 ε immunoprecipitates. Although the 12K structure is relatively faint in the exposure shown in Fig. 4*a*, it was more prominent in longer exposures of this same autoradiogram (data not shown). In contrast to T lymphocytes, anti-CD3 ε immunoprecipitates prepared from NK cell lysates did not contain any component of the TCR complex (Fig. 4*b*, *c*). In spite of the fact that these cells express small amounts of CD3 ε mRNA, they do not contain detectable amounts of CD3 ε protein. Consistent with the flow cytometry and immunoblotting data shown in Figs 2 and 3, immunoprecipitates formed using the ζ TCR reactive antibody TIA-2 contained significant amounts of ζ migrating as two distinct 16K spots off the diagonal. The migration patterns of proteolytic digests prepared from these 16K proteins were identical (data not shown), suggesting that in NK cells, ζ is expressed, in approximately equal amounts, as a disulphide-linked homodimer and as a disulphide-linked heterodimer with the 12K structure mentioned above (arrow, Fig. 4*b*, *d*). We were unable to obtain sufficient quantities of the 12K protein to compare it to ζ by proteolytic mapping. It is possible that the 12 K protein arises from a proteolytic cleavage of one of the chains of the ζ homodimer. Additional experiments will be required to determine whether these disulphide-linked subunits are structurally related.

In addition to ζ, higher molecular weight structures were also included in these immunoprecipitates. In NK clone JJ1 (Fig. 4*b*), this structure migrated as a 60-70K spot above the diagonal that appears to be the same structure identified in T-cell lysates (Fig. 4*a*). In NK clone JT_B18, this structure migrated as an 80-90K on diagonal spot (Fig. 4*c*). Interestingly, polyclonal populations of $CD3^-$ peripheral blood NK cells expressed a ζ complex that appeared to associate with both of the higher molecular weight forms identified in these clones (Fig. 4*d*). Because of their non-covalent association with ζ, we cannot be certain that these structures retain their association with ζ in the cell. If they are functionally important components of the ζ receptor complex on NK cells, the fact that they can also be

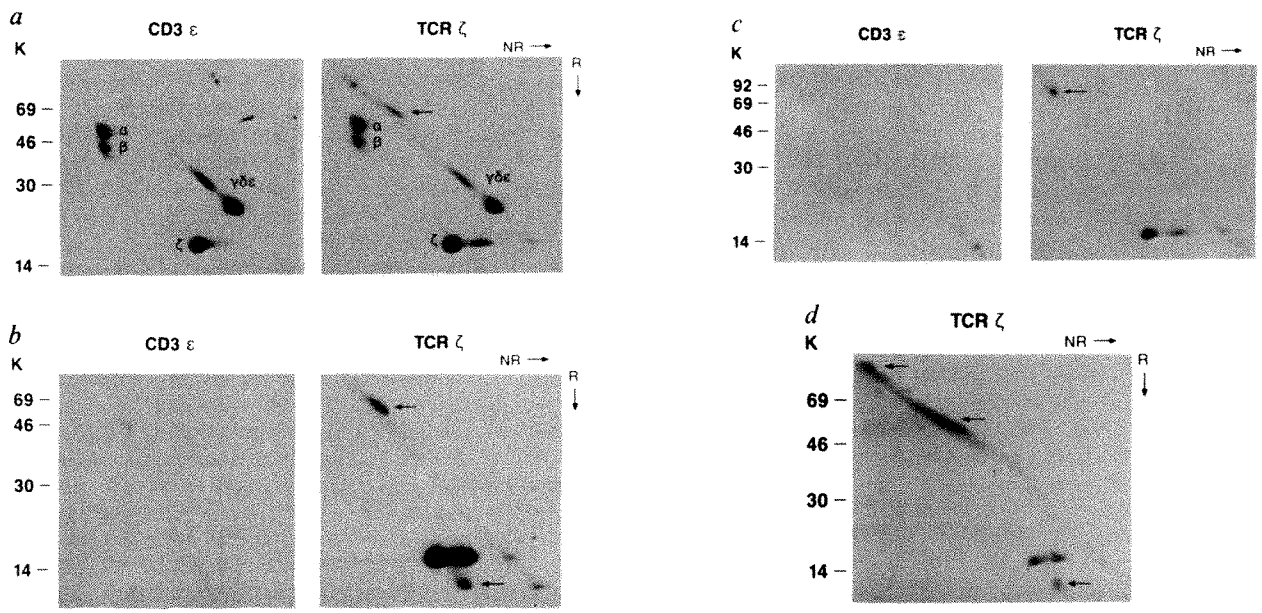

FIG. 4 Immunoprecipitation analysis using non-reducing/reducing diagonal gel electrophoresis. Left panels, CD3 ε immunoprecipitates. Right panels, ζ TCR immunoprecipitates. *a*, Immunoprecipitates from peripheral blood T-cell lysates; *b*, Immunoprecipitates from NK-clone JJ1; *c*, Immunoprecipitates from NK-clone JT_B18; *d*, Immunoprecipitates from peripheral-blood NK cells prepared as described in the legend to Fig. 1. The relative migration of molecular size markers are indicated on the left. Arrows point to the 12K ζ associated structure (*b* and *d*), the 60-70K ζ associated structure (*a*, *b* and *d*) and the 80-90K ζ associated structure (*c* and *d*).
METHODS. Peripheral blood T lymphocytes, NK clones JJ1 and JT_B18, and peripheral blood NK cells were permeabilized with digitonin, radioiodinated, and immunoprecipitated from digitonin lysis buffer (1% digitonin, 0.12% Triton X-100, 150 mM NaCl, 1 mM PMSF, 20 mM triethanolamine, pH 7.8) using monoclonal antibodies reactive with CD3 ε (Leu 4) (ref. 33) and ζ TCR (TIA-1) as previously described[20]. Because ζ TCR is poorly labelled by surface iodination, cells were routinely permeabilized before being radiolabelled. When unpermeabilized lymphocytes were radioiodinated and immunoprecipitated as described above, some labelling of ζ TCR could be obtained, and the ζ containing complex was similar to that observed using permeabilized cells. Electrophoretic analysis by non-reducing/reducing diagonal gel electrophoresis was as described[20]. The first dimension, run under non-reducing (NR) conditions is depicted in the horizontal direction, whereas the second dimension, run under reducing (R) conditions is depicted in the vertical direction.

found in T cells is of great interest. It has been known for some time that a subpopulation of $CD3^+$ T lymphocytes is capable of NK-like, non-MHC restricted killing of tumour targets[21,22]. It would, therefore, not be surprising if a subpopulation of both NK cells and T cells shared a receptor structure capable of mediating this effect.

The expression of ζ TCR in $CD3^-$ NK cells has important implications for the activation and function of these cells. Recent evidence suggests that ζ TCR plays a pivotal role in T-cell activation initiated through the T-cell receptor complex. If ζ plays a similar role in NK cells, the fact that it is found in association with additional structures not part of the CD3-TCR complex may be very important. Our results suggest that in both T cells and NK cells, ζ can exist as a disulphide-linked homodimer of 32K or as a disulphide-linked heterodimer with a 12K structure. In NK cells, ζ is also associated with additional higher molecular weight structures that appear to differ on individual clones. Although additional experiments will be necessary to fully elucidate the role of the NK cell ζ complex in non-MHC restricted killing, the identification of a ζ containing molecular complex in NK cells immediately suggests an explanation for some of the functional properties of these cells, and points to the requirement for future research aimed at understanding the receptor complex used by this lymphocyte subset. □

The LDL-receptor-related protein, LRP, is an apolipoprotein E-binding protein

THE low-density-lipoprotein (LDL) receptor is a cell-surface protein that plays an important part in the metabolism of cholesterol by mediating the uptake of LDL from plasma into cells[1]. Although LDL particles bind to the LDL receptor through their apolipoprotein B (apo B) and apolipoprotein E (apo E) moieties, other apo E-containing particles, like chylomicron remnants, are not dependent on the LDL receptor for uptake into cells. Chylomicrons formed in the intestinal mucosa during the absorption of the products of digestion, are processed by the peripheral circulation by lipoprotein lipase, which catalyses the breakdown of triglycerides in chylomicrons to free fatty acids and glycerol. The resulting chylomicron remnants, which are cholesterol-rich lipoproteins, are subsequently taken up in the liver[2–6]. A second distinct protein that binds to apo E-containing lipoproteins, but not to LDL, has been proposed to be the receptor mediating the clearance of chylomicron remnants from the plasma. This protein has a relative molecular mass (M_r) of 56,000 (56K)[7]. More recent studies have failed, however, to establish whether this protein is a cell-surface receptor[8]. Here we describe crosslinking experiments in which apo E liposomes were found to bind specifically to the cell surface of hepG2 cells and to human liver membranes. The size and immunological cross-reactivity of the protein to which the liposomes bound was indistinguishable from that of the recently cloned and sequenced LDL-receptor-related protein, LRP[9]. We therefore conclude that the LRP might function as an apo E receptor.

Several lines of evidence exist for the presence of a second distinct receptor that binds apo E-containing chylomicron remnants in the liver[2–6]. In particular, the uptake of chylomicron remnants that contain apo E remains normal in animals with defective LDL receptors[10]. It is extremely difficult, however, to demonstrate a specific apo E receptor because the LDL receptor also binds to apo E with an even higher affinity than it does to the apo B of high relative molecular mass, apo B-100 (ref. 11). To differentiate between the receptors, we have previously used the approach of ligand blotting. Proteins from crude membrane fractions of human liver were electrophoretically separated, transferred to nitrocellulose filters and incubated with apo E-containing lipoproteins or apo E liposomes. With this method we detected only apo E-binding proteins of M_r 55–58K. Two proteins in this band were further analysed and found to be intracellular enzymes[8]. We report here the results of an alternative approach in which labelled apo E liposomes were bound and covalently crosslinked to apo E-binding proteins on intact cells. After subsequent solubilization we identified the major binding activity in a band corresponding to an M_r of ~600K that was indistinguishable from the band for LRP.

The first series of experiments were done with an ^{125}I-labelled heterobifunctional crosslinking agent that was coupled to apo E 3/4 by means of an amide linkage (*N*[4-(p-azido-m-[^{125}I]iodophenylazo)benzoyl]-3-aminopropyl-*N*'-oxysuccinimide ester; refs 12 and 13). After incubating labelled apo E liposomes with intact cells, unbound ligand was removed and covalent linkage induced by photoactivation. Subsequent cleavage of the intramolecular azo linkage with sodium dithionite leaves the ^{125}I-label on the binding protein rather than on the ligand. For these experiments we chose HepG2 (a human hepatocyte line) and P388 (a mouse macrophage line) cells because these cells

† Present addresses: Department of Molecular Genetics and Internal Medicine, UTHSCD, 5323 Harry Hines Boulevard, Dallas, Texas 75235, USA (J.H.) and the Heart Research Institute, 145 Missenden Road, Camperdown, New South Wales 2050, Sydney, Australia (K.K.S.).

contain much higher amounts of LRP than of the LDL receptor, especially if the cells are grown in fetal calf serum, when the LDL receptor is down-regulated. Figure 1 shows that the principal apo E-binding protein was very large, with an estimated M_r of ~600K. Autoradiography of the gels after transfer of the proteins to nitrocellulose filters enabled the mobility of the LRP to be determined on the same filter by western blotting. Although the bands were weak, the most heavily stained band coincided with the radioactively labelled apo E-binding protein (data not shown).

Because the LRP has a predicted M_r of 503K and contains many possible glycosylation sites[9], we investigated the possible identity of the ~600K apo E-binding protein with the LRP using crosslinking experiments on metabolically labelled cells. In this case a photoreactive heterobifunctional crosslinker was used (*N*-succinimidyl (4-azidophenyl)1,3'-dithioproprionate, SADP), which is cleavable with dithiothreitol (DTT). The experiments were performed as follows: HepG2 cells were preincubated for 4 h with [^{35}S]methionine to allow metabolic labelling of cellular proteins. After binding and cross-linking of apo E, the cells were solubilized with Nonidet P40. The lysates were then immune-precipitated in parallel with polyclonal antisera raised against apo E or the cytoplasmic tail of the LRP. Before electrophoresis, the immune-precipitates were reduced with DTT to separate the apo E from its cell-surface binding protein and restore it to its true M_r. The results in Fig. 2 show that the apo E binds to a band corresponding to an M_r of ~600K, which is indistinguishable from the band for LRP. The specificity of the LRP immune-precipitation was shown by competition with the peptide against which the antibody was raised (Fig. 2*b*, lane 3). The anti-apo E antibody did not immune-precipitate as much protein as the anti-LRP serum because at 4 °C apo E liposomes could only bind to the fraction of LRP on the cell surface, whereas the anti-LRP incubated with cell lysate could bind to all the LRP. Only a proportion of the total LRP was present on the cell surface at any one time (D. Murfitt and K.K.S., manuscript in preparation).

In a third series of crosslinking experiments, we looked for specific competition between the binding of apo E-containing liposomes and triglyceride-rich remnants (derived from very-low-

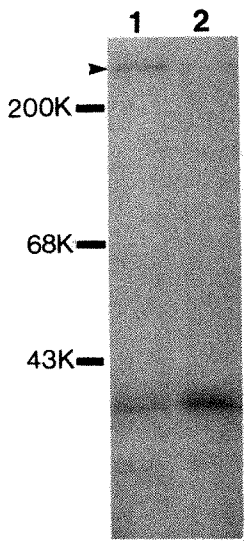

FIG. 1 Crosslinking of apo E liposomes to a surface protein of M_r ~600K on HepG2 cells (lane 1) and mouse macrophages (P-388, lane 2). Reconstituted apo E 3/4 liposomes[15] were coupled to ^{125}I-iodinated Denny Jaffe reagent and incubated with cells in lipid-free medium. After photoactivation and cleavage of the crosslinker, the cells were solubilized and comparable amounts of radioactivity were applied to an 8% SDS-polyacrylamide gel[16]. Proteins were transferred to nitrocellulose by electroblotting and autoradiographed for 17 days. An arrow marks the crosslinked band corresponding to an M_r of ~600K which is radiolabelled; the band corresponding to an M_r of 34K represents the residual apo E-Denny Jaffe complex.
METHODS. Apo E 3/4 (220 μg) in sodium borate buffer (1 ml, pH 8) containing sodium cholate (23.4 mg) was added to a lipid film of egg-lecithin (2 mg) and cholesterol (40 μg). The mixture was vortexed for 1 min, gently shaken for 2 h at 24 °C, and finally dialysed against borate buffer, pH 8, for 48 h at 4 °C. The liposomes were isolated on a Sepharose CL 6B column as a homogenous peak and checked on an SDS-polyacrylamide gel for intact apo E. These proteoliposomes (15 μg) were coupled to 0.1 nmol (200 μCi) of Denny Jaffe reagent (NEN, NEX 227) according to the manufacturer's instructions. Cell monolayers (~10^7 cells) were cultivated in DMEM containing 10% fetal calf serum and maintained in serum-free medium for 30 min before the experiment began to avoid direct lipoprotein contact. For the binding reaction the cells were incubated for 2 h at 4 °C with the apo E-Denny Jaffe complex. After the washing steps, photoactivation was with 366 nm UV light for 8 min. To cleave the linkage, the cells were treated with 200 mM dithionite. The cells were then solubilized in 200 μl Tris-HCl (50 mM, pH 8) containing 2% Triton X-100. The insoluble material was spun down for 10 min at 100,000 r.p.m. in a Beckmann TL-100 ultracentrifuge before PAGE.

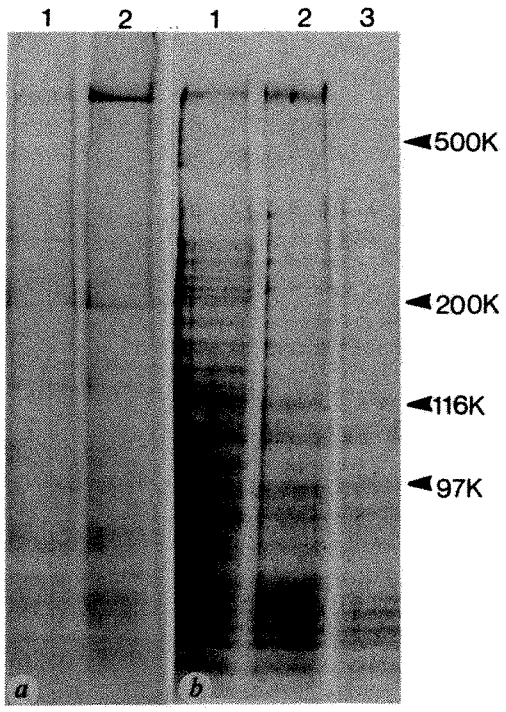

FIG. 2 Apo E-binding protein and LRP are indistinguishable. Metabolically labelled HepG2 cells were crosslinked to apo E liposomes using SADP (Pierce) and then immunoprecipitated using either anti-apo E or anti-LRP antisera. Before loading on SDS-polyacrylamide gels, the crosslinked proteoliposomes were dissociated in DTT. Two separate experiments are shown (*a* and *b*). Lane 1, polyclonal anti-apo E; lane 2, polyclonal anti-LRP serum; lane 3 (in *b* only), polyclonal anti-LRP serum in the presence of the peptide antigen against which the antibody was raised[9] showing that the band corresponding to an M_r of 600K is specific.
METHODS. HepG2 cells in Petri dishes (10 cm) were metabolically labelled with [^{35}S]methionine (200 μCi) for 4 h. Apo protein E 2/2 (50 μg) reconstituted proteoliposomes (as described in Fig. 1) were coupled to the crosslinker SADP and incubated for 2 h at 4 °C with the ^{35}S-labelled HepG2 cells in Earle's salt solution (EBSS: Gibco). After washing, the bound apo E was crosslinked by photoactivation at 254 nm for 15 min and the cells then solubilized in Tris HCl (20 mM, pH 7.5), NaCl (150 mM), $MgCl_2$ (2 mM) containing 1% Nonidet P40. Solubilized cells from one Petri dish were split and incubated with 50 μl anti-LRP serum or 50 μl anti-apo E serum overnight. For peptide competition, 10 μg peptide was added to the antibody dilution before addition to the lysate. Immune complexes were immunoprecipitated by addition of 200 μl of a 1:1 suspension of protein A-Sepharose in the same buffer and incubation for 2 h at 4 °C. The samples were then centrifuged, and after extensive washing of the immunoprecipitate, the crosslinker was cleaved by addition of DTT (20 mM) and 5% SDS. The protein A-Sepharose was separated by centrifugation and a third of the supernatant loaded on a 6% SDS-polyacrylamide gel.

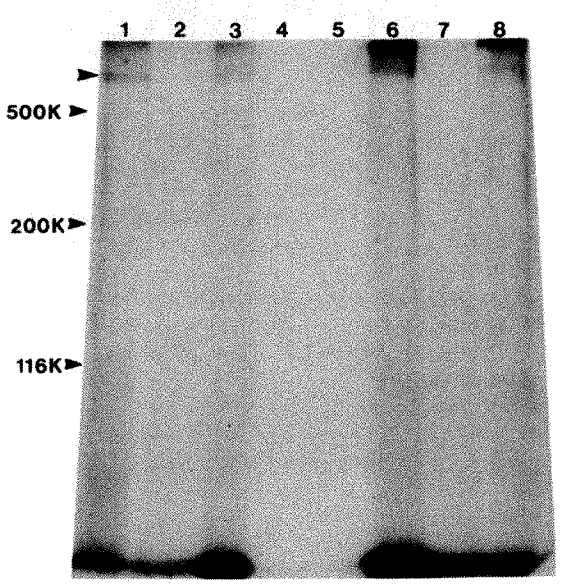

FIG. 3 Triglyceride-rich remnants compete for apo E binding to the LRP on HepG2 cells and human liver membranes[17]. About 10^7 cells (lanes 1–4) or 400 μg membrane protein (lanes 5–8) were incubated for 1 h at 4 °C with 17 μg of ^{125}I-iodinated apo E 3/4 liposomes (specific activity of 29.5×10^4 c.p.m. μg^{-1}) either alone (lanes 1 and 6), in the presence of excess triglyceride-rich remnants (425 μg protein; lanes 2 and 7) or with the addition of 2 mM EDTA (lanes 3 and 8). Lanes 4 and 5 represent control cells that received no apo E liposomes. Bound apo E was crosslinked to the cells after washing using disuccinimidyl suberate (DSS; Pierce) solubilized as described in Fig. 2 and loaded on a 6% SDS-polyacrylamide gel. Proteins were transferred to nitrocellulose and autoradiographed for 4 days.

METHODS. Triglyceride-rich remnants (apo E isotype 3/4) were isolated by density gradient centrifugation from a patient with remnant accumulation. Purified apo E 3/4 was iodinated using iodogen[18] and reconstituted into liposomes as described in Fig. 1. Crosslinking was performed on washed cells or membranes using DSS in dimethyl sulphoxide at a final concentration of 1 mM for 30 min at room temperature.

density lipoproteins and chylomicrons). We also tested whether binding was sensitive to inhibition by EDTA. Because the shift in M_r did not matter in these experiments, we used a non-cleavable crosslinker (disuccinimidyl suberate). The results are shown in Fig. 3. The decoration of the band corresponding to an M_r of about 600K by ^{125}I-labelled apo E 3/4 liposomes was inhibited by incubation in the presence of excess unlabelled triglyceride-rich remnants when HepG2 cells or human liver membranes were used as the protein source (lanes 1 and 6 compared with lanes 2 and 7). With HepG2 cells, but not with the liver membranes, EDTA caused a decrease in, but not total inhibition of binding (Fig. 3, lanes 3 and 8). This indicates that the binding of apo E to LRP is not dependent on divalent cations, despite the strong binding of calcium ions to detergent-treated LRP on blots[9]. Because comparable amounts of LRP were present in all the lanes, as determined by immunoblotting of the same filter with anti-LRP antibody (data not shown), we conclude that the binding of apo E liposome is competitively inhibited by lipoprotein particles that contain apo E. Definitive studies on the binding properties of LRP must await biochemical purification of the protein.

We have shown using three different types of crosslinking reagents that the protein to which apo E liposomes bind in HepG2 cells, P388 cells and human liver membranes is indistinguishable from LRP, based on M_r and immunological criteria. Both apo E 2/2 and apo E 3/4, which contain all three apo E isoforms, are recognized by the LRP in a manner competed by natural apo E-containing particles. The binding of apo E 2/2 to the LRP could explain why patients homozygous for apo E 2/2 do not necessarily have elevated lipid levels, despite the inability of remnants containing apo E 2/2 to bind to the LDL receptor[14]. Binding is also relatively independent of added EDTA, as would be expected for the chylomicron-remnant receptor[4]. It remains to be explained, however, why LRP is so widely distributed among tissues[9] if its function is solely to bind chylomicron remnants. □

The codon CUG is read as serine in an asporogenic yeast *Candida cylindracea*

Yoshiyuki Kawaguchi, Hiroshi Honda, Junko Taniguchi-Morimura & Shinjiro Iwasaki

Tokyo Research Laboratory, Meito Sangyo Co. Ltd., 2973-2 Ishikawacho, Hachioji, Tokyo 192, Japan

DEVIATIONS from the universal genetic code have been reported for several microorganisms. Termination codons are used for coding some amino acids in *Paramecium*[1,2], *Mycoplasma*[3] or *Tetrahymena*[4,5], and in *Escherichia coli*, the UGA termination codon is used to code for selenocysteine[6]. In mitochondria, the changes of sense codons to termination codons or to codons encoding other amino acids have also been reported[7,8]. Here we report another example of divergence from the universal code, this time in a non-spore-forming yeast *Candida cylindracea*, in which the universal codon for leucine, CUG, is used to code for serine. This conclusion is based on the observations that: (1) the amino-acid composition and the partial amino-acid sequences of an extracellular lipase from this yeast agreed with those deduced from the complementary DNA if CUG was assumed to specify serine; and (2) serine, but not leucine, was incorporated into a polypeptide in a cell-free translation system from this yeast in the presence of a synthetic CUG oligomer.

Candida cylindracea[9] strain MS-5 (deposited as *Candida rugosa* ATCC14830) produces two kinds of extracellular lipase—lipase I of M_r 60,000 is the main component and lipase II (M_r 60.5K) is the minor component[10]. From this strain we isolated a mutant that produced a large amount of lipase I and a negligible amount of lipase II. We constructed a cDNA library from this mutant, from which a clone carrying the longest lipase I cDNA was obtained. This clone was named λCL115 (see Fig. 1 legend). We sequenced this cDNA and deduced its corresponding 534-amino-acid sequence which contained a sequence identical to that of the N-terminal portion (residues 1–20) of lipase I (Fig. 1). Part of the putative signal sequence was found upstream of the N terminus. Other cDNA clones with shorter inserts were also sequenced. Their sequences coincided almost exactly with those of the corresponding parts of the λCL115

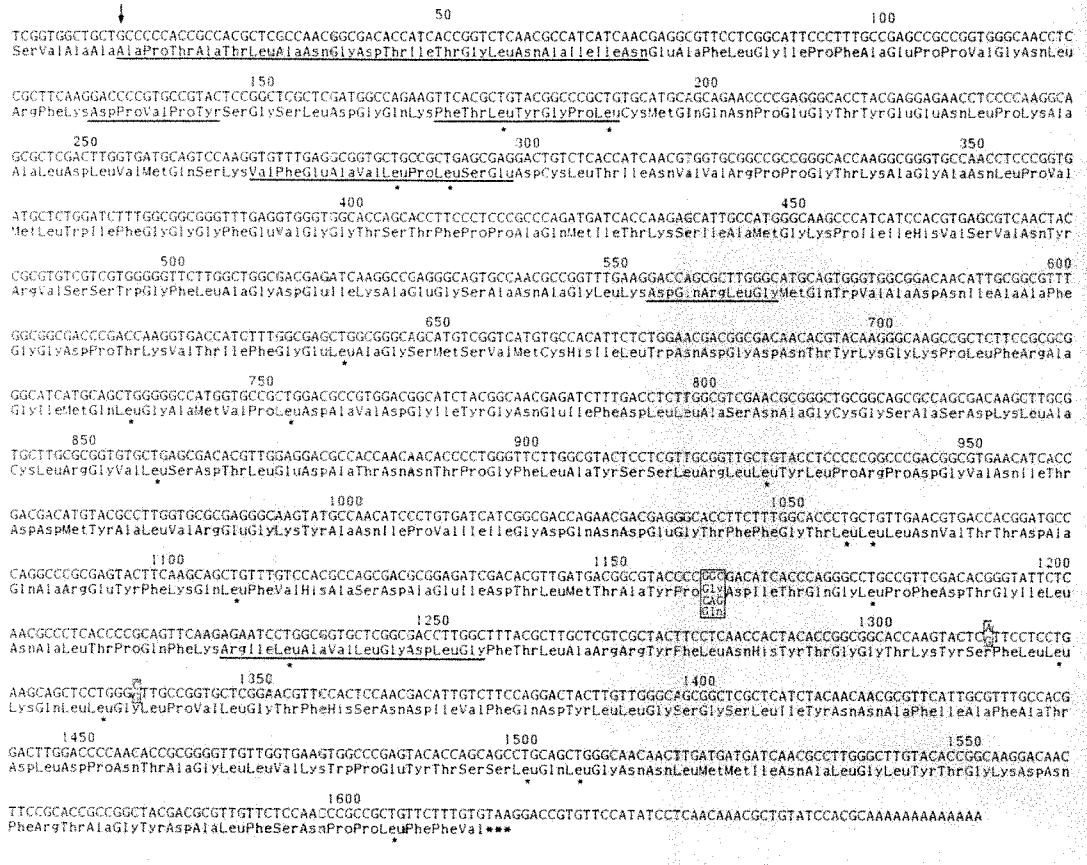

FIG. 1 Nucleotide sequence of the cDNA from λCL115 and its deduced amino-acid sequence according to the universal code. N terminus of lipase I is indicated by an arrow. The determined amino-acid sequences of the N terminus of lipase I and the portions corresponding to the sequences of the peptides of lysyl endopeptidase digests (see Fig. 2 legend) are underlined. Examples of nucleotide and amino-acid substitution sites are boxed. CTG codons are indicated by asterisks. METHODS. Poly(A)$^+$RNA from the *C. cylindracea* mutant that was cultured in medium containing 2% soybean oil was extracted by the guanidium/caesium chloride method[16] followed by chromatography on oligo(dT)-cellulose. Using this poly(A)$^+$RNA as a template, a cDNA library was prepared using λgt11[17] as a vector. From this library, clones carrying the partial cDNA sequences of lipase I were selected by immunodetection with anti-lipase I antibody according to the method described by Young and Davis[18]. Clones carrying the longer cDNAs were screened by plaque hybridization with the above cDNA as a probe. The clone carrying the longest cDNA was named λCL115. Complementary DNAs were sequenced by the dideoxynucleotide chain-termination method[19].

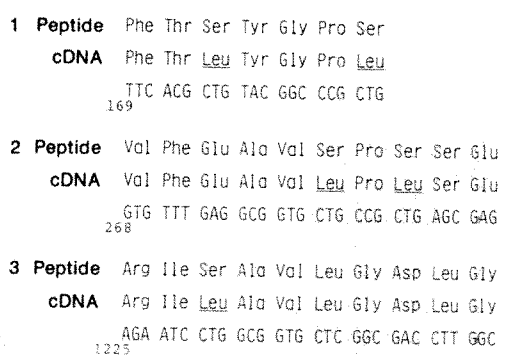

FIG. 2 Amino-acid sequences of the peptides from lipase I. Purified lipase was digested with lysyl endopeptidase (*Acromobacter* protease I), and the peptides were separated by reverse-phase HPLC using a μBondapak C18 column (Waters). The N-terminal amino-acid sequences of the five peptides were determined with a gas-phase peptide sequencer (Applied Biosystems) (Fig. 1, underlined). The three peptides whose sequences disagreed with the cDNA sequence are illustrated. The upper line is the sequence derived from the peptide and the lower is that from the cDNA. Leucine residues corresponding to CTG are underlined.

TABLE 1 Codon usage in lipase I mRNA

Numbers indicate the frequency with which the codons are used in the coding region of lipase I mRNA with the exception of the putative signal sequence. The numbers of Leu and Ser residues, calculated by assuming that CTG encodes Ser, are 48 and 45, respectively. Those determined from amino-acid analysis were 47 and 43, respectively. Asterisk denotes that the amino acid encoded by CUA is unknown. —, Stop codons.

cDNA apart from containing a few nucleotide substitutions, some of which caused substitution of amino acids (Fig. 1). These results indicate that in *C. cylindracea*, homologous genes encode several homologous lipase I proteins, which differ by a few amino-acid substitutions.

The amino-acid composition of purified lipase I was consistent with that deduced from the cDNA sequence, with the exception of the contents of leucine and serine, which were found to differ significantly.

To discover the reason for this discrepancy we sequenced the internal region of lipase I. Figure 2 shows the partial amino-acid sequences of the peptides isolated from lysyl endopeptidase digests of lipase I and the corresponding sequences deduced from the cDNA. At all of the sites in the peptides encoded by CTG, leucine was substituted by serine. When the amino-acid sequence corresponding to the cDNA was re-deduced by regarding CTG as a codon specifying serine, it showed good agreement with the contents of leucine and serine found in the protein

(Table 1 footnote). These results suggested that *C. cylindracea* uses CUG as a serine codon.

To obtain direct evidence for the coding of serine by CUG, we performed an *in vitro* translation experiment with a synthetic CUG oligomer prepared as described in Fig. 3*a*. This artificial messenger RNA was introduced into cell-free translation systems from cells of either the mutant *C. cylindracea* or *Saccharomyces cerevisiae* JCM7255, and the incorporation of [^{3}H]serine or [^{3}H]leucine was then monitored (Fig. 3*b*). An AUC pentamer was incorporated into the mRNA with the expectation that the resulting isoleucine pentamer structure would facilitate precipitation of the translation product by trichloroacetic acid. In the *S. cerevisiae* system, [^{3}H]leucine incorporation was dependent on the amount of mRNA present. In the *C. cylindracea* system, however, incorporation of [^{3}H]leucine did not increase beyond the endogenous level, although uptake of [^{3}H]serine was observed to parallel the amount of mRNA added. In each system, incorporation of both leucine and serine was induced by the addition of poly(A)$^+$RNA from *C. cylindracea* or globin mRNA (data not shown). Similar results were obtained in the system from a wild-type strain of *C. cylindracea*. These results strongly indicated that CUG is used as a serine codon in *C. cylindracea*.

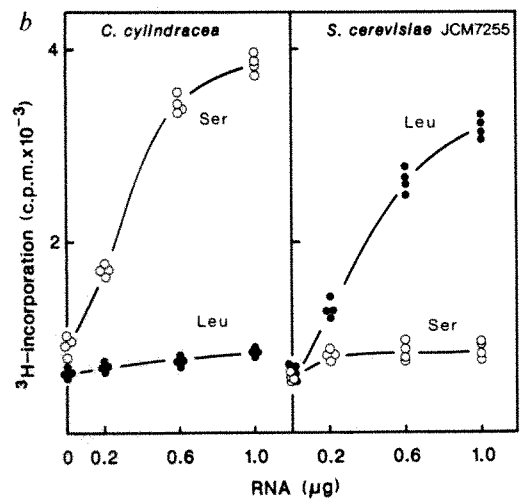

FIG. 3 Incorporation of serine coded by CUG in the cell-free protein-synthesizing yeast systems. *a*, Synthetic oligodeoxynucleotide was inserted between the *Hin*dIII and *Bam*HI sites of pSP64 (Promega)[20] downstream from the SP6 promoter and introduced into *E. coli* HB101 by transformation. The resulting plasmid was made linear with *Pvu*II and used as a template for transcription by SP6 RNA polymerase *in vitro*[20]. The transcript was then capped with guanylyltransferase (BRL)[21] for use as an artificial mRNA. *b*, *In vitro* translation was performed with a cell-free system prepared as described by Gasior *et al.*[22]. Fifty microlitres of translation mixture contained 20 μl yeast cell-free extract, 0–1 μg of RNA synthesized as in *a* and 0.5 μM [^{3}H]leucine or [^{3}H]serine. After 1 h of incubation at 20 °C, aliquots (10 μl) from each incubation tube were analysed by counting hot acid-insoluble radioactivity.

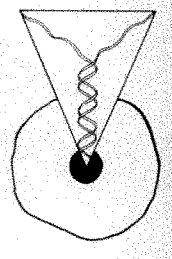
The amino-acid substitution observed would not have been a suppression, which takes place under a specific cellular condition, because both the mutant and wild-type *C. cylindracea* nearly constitutively produced lipase I in large amounts, and CUG is frequently used in lipase I mRNA (Table 1). Possible causes of the codon alteration are (1) a mutation of a transfer RNA^{Ser} at the anticodon, or (2) a mutation of tRNA^{Leu} at the aminoacyl-tRNA synthetase(AAS) recognition site. Normanly *et al.*[11] reported the complete conversion of tRNA^{Leu} to tRNA^{Ser} without a change at the anticodon. Other possibilities, such as mutations of AAS[12] or ribosomal missense mutations[13,14], cannot be excluded. The mechanism of the change in the codon specificity could be elucidated by isolation and analysis of the tRNA^{Ser} that binds to CUG.

According to the wobble rule, not only CUG but also CUA may be read to specify serine in *C. cylindracea*. The codon CUA, however, is not used in the coding frame of lipase I cDNA (Table 1). We have found CUG codons in the open reading frames of several unidentified cDNAs other than lipase I cDNA but as yet have not found CUA codons. Further work is required to determine whether CUA is used to specify serine in *C. cylindracea*.



Another remarkable feature of the *C. cylindracea* genome is the existence of a large number of pseudogenes. Several such sequences previously analysed have more than 90% homology with the lipase I cDNA (data to be reported elsewhere). Codon alteration in mitochondria or *Mycoplasma* is thought to be potentially useful for economic use of limited amounts of genetic material[15]. Our results, however, indicate that such abnormal codon usage can take place even in organisms possessing a genome with highly repetitive sequences. It is unlikely that such a phenomenon occurs in only a single microbial strain, and it would be interesting to clarify the distribution of similar codon alterations in other microorganisms. □

ACKNOWLEDGEMENTS. We thank Professor Emeritus Bunji Maruo of The University of Tokyo for discussion and Professor Teruhiko Beppu of the University of Tokyo for advice and reviewing the manuscript.

BOOK NOW WHILE PLACES REMAIN

How readily can the genes responsible for predisposition to conditions such as ischaemic heart disease or schizophrenia be identified? What are the prospects of human gene therapy? Are transgenic animals the key to understanding the precise genetic control of development? How much more sophisticated can methods of genetic manipulation and gene identification become?

These are among the major questions that will be addressed by the distinguished speakers at Nature's 1989 conference. A chairman will outline the context and aims of each session, the speakers will review their area of expertise and report the latest advances, and a rapporteur will draw out the implications of each session. There will be a panel discussion of the ethical and legal problems raised by human gene research and therapy. For the convenience of delegates, the second day of the conference will finish in mid-afternoon, whereas the first day will be extended by the panel session followed by a wine and cheese reception.

We expect the conference to sell out well before opening, so urge you to make sure of your place now by returning the form below.

CONFERENCE SESSIONS

1 HUMAN GENETIC DISEASE
James Crow, U. of Wisconsin (chairman)
Louis Kunkel, Harvard Medical School
Gerd Utermann, University of Innsbruck
Kenneth Kidd, Yale University
Eric Lander, Whitehead Institute (rapporteur)

2 PROSPECTS FOR GENE THERAPY
Leon Rosenberg, Yale (chairman)
Irving Weissman, Stanford University
Richard Mulligan, Whitehead Institute
French Anderson, NIH
David Baltimore, Whitehead (rapporteur)

3 HUMAN GENE RESEARCH: PANEL DISCUSSION

4 TRANSGENIC MOUSE MODELS
Richard Palmiter, Washington U. (chairman)
Douglas Hanahan, University of California SF
Erwin Wagner, IMP Vienna
Ron Evans, Salk Institute
Brigid Hogan, Vanderbilt U. (rapporteur)

5 GENE DISRUPTION AND DEVELOPMENT
Mario Capecchi, U. of Utah (chairman)
Fred Alt, Columbia University
Janet Rossant, University of Toronto
Peter Gruss, Max Planck Institute Gottingen
Bruce Alberts, U. of California SF (rapporteur)

GENE MANIPULATION IN BIOLOGY AND HUMAN DISEASE: 9–10 November 1989

REGISTRATION FEES
Standard rate including reception

Special rate for full-time academics and government employees only $300

Sponsor's liability: should the conference be cancelled or postponed for any reason, the sponsor's liability is limited to the return of the registration fee. Cancellation policy: all cancellations must be received in writing. Cancellations before 30 August will be subject to $25 service charge. No refunds will be made after that date. Registrants unable to attend may send a substitute.

Please reserve ____ places for me at Nature's conference 9–10 Nov 1989
Total amount due: US$ _____

ANNOUNCING AN IMPORTANT EVENT IN SCIENCE PUBLISHING!

THE MACMILLAN MOLECULAR BIOLOGY SERIES

General Editor: Dr C J Skidmore, University of Reading

MACMILLAN MOLECULAR BIOLOGY

Genetic Elements in *Escherichia coli*

by Dr Peter Smith-Keary

Written for students of molecular genetics and molecular biology, the first volume in the series sets the scene by introducing aspects that provide the scientific background for the major technical advances of genetic engineering. Central topics such as replication, mapping, mutation, transposition and both general and site specific recombination are fully documented.

PB *0333 442687* **£9.95** **HC** *0333 442679* **£25.00**

Organelles

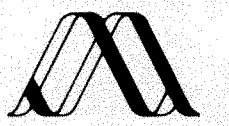
by Dr Mark Carroll

Aimed at second and third year undergraduate students following courses in biochemistry and cell biology, Organelles draws together the latest developments in our understanding of the ultrastructure and function of cell components. Each major cell organelle is the subject of one complete chapter, which ends with self-study questions to focus the reader on central concepts and principles. Throughout the book there are numerous micrographs and line illustrations.

PB *0333 44244X* **£9.95** **HC** *0333 442431* **£25.00** *(February 1989)*

Forthcoming titles include:

What is a Gene? by Dr C J Skidmore
Protein Biosynthesis by Dr R Jagus
The Molecules of the Cytoskeleton by Dr L Amos and Dr W B Amos



Code 355

ORDER FORM

Paperback copies are available on inspection to lecturers in the UK where this may result in an adoption of 12 or more copies. If you would like an inspection copy please indicate in the space provided and return this form to: Inspection Copy Department, Macmillan Education, FREEPOST, Houndmills, Basingstoke, Hants RG21 2BR.

Scintillation proximity assay

N. Bosworth and P. Towers

Fluomicrospheres coated with antibodies or receptors eliminate the need to separate bound from free ligand in both radioimmunoassays and ligand-binding assays.

MANY advances have been achieved in radioimmunoassays (RIA) and ligand-binding assays (LBA) in recent years, but the physical separation of bound from free ligand still remains a time-consuming operation that cannot be automated and that often can lead to increased non-specific binding. Both RIA and LBA expose researchers to the hazards of manipulating radioactive solutions of sometimes unknown biological activity. Tritium-based assays require the use of liquid scintillant, which is flammable, toxic and expensive to purchase and dispose.

Amersham International has used scintillation proximity assay (SPA) systems[1–7] to overcome the problems outlined above. SPA involves the use of fluomicrospheres coated with acceptor molecules, such as antibodies or receptors, to which a ligand will bind selectively in a reversible manner.

The technique is carried out in normal assay buffers, and requires the use of a ligand labelled with an isotope that emits low-energy radiation which is dissipated easily into an aqueous medium. It is fortunate that two of the most widely used isotopes in life science research — ^{3}H and ^{125}I — possess ideal emission characteristics for their use in SPA.

Because ^{3}H β-particles and ^{125}I Auger electrons have average energies of 6 and 35 keV, respectively, their energies are absorbed by aqueous solutions within very small distances (4 μm for ^{3}H β-particles and 35 μm for ^{125}I Auger electrons). The mean path length of ^{125}I gamma emission is 15 cm, so very little of the energy is absorbed by the fluomicrospheres or the buffer.

Bound and free

At any point during an assay, bound labelled ligands will be in close proximity to the fluomicrospheres, allowing the emitted energy to activate the fluor and produce light. Because the assay typically is carried out in 0.4 ml of buffer, the majority of unbound labelled ligands are too far from the fluomicrospheres, which are present in microgram quantities, to enable the transfer of energy. Bound ligands produce light, but free ligands do not, obviating the need for any of the traditional tedious separation procedures (Fig. 1).

The limited amount of published work concerning SPA has been carried out using fluomicrospheres based on organic phosphors, such as diphenyloxazole-latex[6] and polyvinyltoluene plastic scintillator beads[2]. Assays performed using bead fluor complexes prepared by adsorbing organic compounds into a matrix are potentially susceptible to error, because the fluor may leach into the buffer.

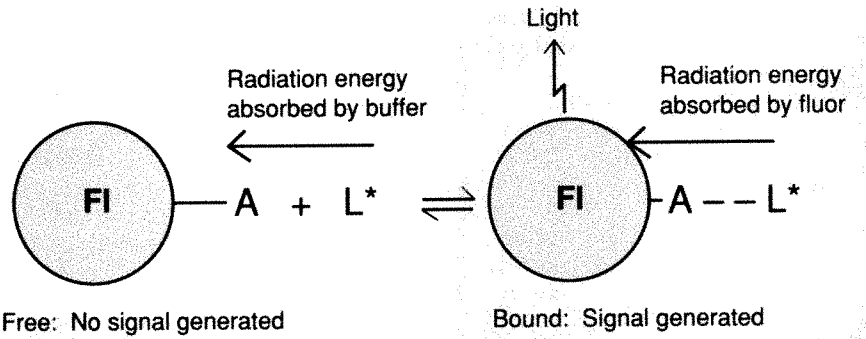

FIG. 1 The principle of scintillation proximity assay: only labelled ligand (L*) that is bound to the acceptor molecule (A) generates a signal on the fluomicrosphere (Fl).

To increase the photon yield and remove the possibility of loss of fluor and subsequent assay drift, Amersham has developed a new type of derivatized inorganic fluomicrosphere based on yttrium silicate. The yttrium silicate is doped selectively with rare earth elements to facilitate the production of light with the optimum emission characteristics for the photomultipliers and electronic circuitry used in commercially available scintillation counters. When used in SPA, these inorganic fluomicrospheres produce up to twice the photon yield compared to any of the currently available organic fluor beads[8].

Amersham has optimized the size of the fluomicrospheres for both RIA and LBA, by balancing a maximal surface area-to-weight ratio against the requirement that the radiation energy be absorbed by, rather than pass through, the fluomicrospheres. Spheres in the size range of 1–5 μm provide a large enough surface area to immobilize a sufficient number of acceptor molecules, and yield a high amount of photons[8].

A range of synthetic methods has been developed to couple acceptor molecules and fluomicrospheres, because physical adsorption onto non-activated fluomicrospheres produces complexes which are not tightly bound and which have poor long-term stability. To overcome the resulting problems of variable assay reproducibility, activated fluomicrospheres (such as those bearing carboxyl, amino, epoxy and aldehyde groups) are used in the coating process. Acceptor-fluomicrosphere complexes coupled covalently using mild, non-denaturing conditions yield optimum assay performance.

Two approaches have been used to convert conventional heterogeneous RIAs into an SPA format. Initially, primary antibodies were coupled directly to functionalized fluomicrospheres (for example, anti-bungarotoxin antibodies for use in a [^{125}I]Bungarotoxin assay). The method proved satisfactory, but incomplete coupling of valuable antibodies was a problem. Amersham now uses a second immunosorbent approach based on anti-rabbit, anti-sheep, anti-mouse, protein A and protein G fluomicrospheres. These have been used to convert over 20 ^{125}I and ^{3}H RIAs for a spectrum of compound types, for example, prostaglandins, leukotrienes, peptides and proteins. The single-tube assay is carried out by adding 0.1-ml quantities of the required reagents and allowing equilibrium to be reached before counting in a scintillation counter. In all of the assays that Amersham has performed, the results produced by the traditional RIA and SPA protocols have been identical.

Receptor studies

Amersham uses SPA technology to study solubilized and membrane-bound receptors. Soluble receptors are attached to fluomicrospheres by chemical bonding, lectin–glycoprotein interaction, or receptor/anti-receptor binding. Solubilized epidermal growth factor (EGF) receptors have been covalently bonded to aldehyde-derivatized fluomicrospheres. One drawback of this non-specific approach is the requirement for relatively pure preparations of receptor isolated from cell membranes.

Improved results are obtained when lectin fluomicrospheres, such as those bound to Concanavalin A or wheat germ agglutinin, are used[8]. The coupling of mouse anti-EGF receptor monoclonal antibody (MAb) that does not affect EGF

ligand binding onto the anti-mouse antibody fluomicrospheres enables the production of saturation and displacement curves using [^{125}I]EGF and Triton X-100 solubilized post-nuclear supernatant cell membrane preparations[8]. If any of the reagents in the complex (fluomicrosphere — anti-mouse antibody — anti-EGF receptor MAb — EGF receptor — [^{125}I]EGF) are omitted, no binding is detected, suggesting the bound complex has the above structure.

Because Scatchard analysis requires bound and free ligand to be in the same unit of measurement, ^{125}I fluomicrospheres have been chemically synthesized as standards so that counts from gamma and scintillation counters can be interconverted. The conversion factor is determined as the ratio of counts obtained using a gamma and a scintillation counter, and is found to be constant regardless of the specific activity, age or label:fluomicrosphere ratio of the standards. Using this conversion factor, the calculated dissociation constants are equivalent to those obtained by more traditional technology.

The coupling of membrane-bound receptors to fluomicrospheres allows the use of general methods that are not possible with solubilized receptors. Fluomicrospheres coated with entities that avidly bind one receptor type present in a membrane leave other receptors available for study (specific [^{125}]transferrin binding is observed when A431 membranes bound to anti-EGF receptor MAb — anti-mouse antibody — fluomicrospheres are used[8]). Fluomicrospheres coated with antibodies to abundant and widely distributed membrane components, such as 5′-nucleotidase and Na+/K+ATPase are employed to study receptors in a variety of cell types, such as A431, KB, C6, rat lung and human placenta.

When these generic fluomicrospheres are used to investigate the β-adrenergic receptor in C6 cell membranes, the correct displacement profile is obtained using [^{125}I]iodocyanopindolol and (+)propranolol, (−)propranolol, (+)isoproterenol, (−)isoproterenol and (−)epinephrine. In a similar manner, LBAs have been developed for a range of receptor types, such as EGF, fibroblast growth factor, nerve growth factor, platelet-derived growth factor, endothelin and transferrin.

The conversion of RIAs and LBAs to SPA methodology confers many unique and significant advantages. Assays can be performed more safely, with fewer 'hands-on' manipulations, and the use of liquid scintillant is not necessary. Costs are also lower because fewer consumables such as tubes and filters are required. The precision of the assays is improved because the only manipulation required is pipetting of reagents, and higher throughputs can be achieved because the technology lends itself to automation.

The future of SPA technology is very exciting, because it solves many of the problems encountered when it is necessary to separate bound and free ligand. There are important concurrent developments in related research areas: antibody and receptor solid-surface coupling methods are being improved, cloned receptors (especially human) are becoming increasingly available, and inorganic phosphors are being developed with higher photon yields. The inevitable availability of more sophisticated scintillation counters will allow the simultaneous counting of many samples. □

Innovative immunology

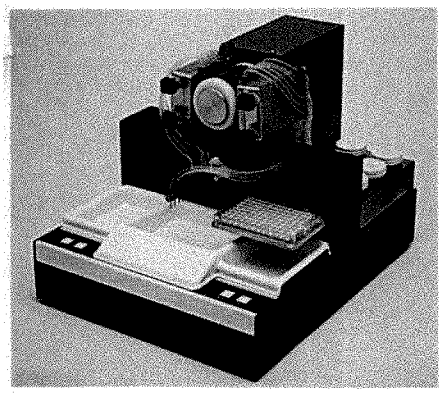
Buffers in tablet form, a bright-blue fluorescent fluorophore, and protein G immobilized to membranes and gels are a selection of this week's new ideas for the immunologist.

AN ANTI-mouse monoclonal isotyping kit for **characterizing mouse monoclonal antibodies** in tissue culture supernatants and ascites is available from Bioproducts for Science, Inc. (*Reader Service No. 101*). The test is based on red cell agglutination technology, and uses a rat MAb specific for a single class/subclass of mouse immunoglobulin that has been coupled to sheep red blood cells. The specific isotyping reagent is mixed with the supernatant under investigation and left for one hour. A positive result (agglutination) is indicated by lattice formation in the well of the plate, and a negative result by "button" formation (no agglutination). The test can detect antibody in the 1–20 µl per ml range, says the company. The $116.30 (US) kits are supplied with enough reagents for 30 tests and include freeze-dried anti-mouse IgG1, IgG2a, IgG2b, IgG3, IgA, and IgM reagent cells and control cells, reconstitution diluent and microtitre plates. Freeze-dried reagents can be stored for 6 months at 4 °C and for 2–3 months when reconstituted, says BPS.

ProAna Mabs is a new system for **monitoring monoclonal antibody production** from EDT Analytical Ltd (*Reader Service No. 102*). Using HPLAC technology developed by Biolytica, the system combines the selectivity of affinity chromatography with the speed and efficiency of HPLC. Central to the system is a patented Fc receptor that is specific for IgG. The £950 (UK) ProAna Mabs system comes as a kit containing a step-by-step manual, ProAna Mabs column, IgG standard, binding and eluting buffers, precolumn filter, 1-ml sample loop, and all the fittings necessary for rigging the column up to any HPLC machine. The sample is injected into the HPLC system, the column is washed and the antibodies are eluted: MAb concentration is determined by the UV detector — a procedure which EDT says takes 10 minutes. The ProAna Mab column can be used over 1,000 times without a reduction in yield, says EDT.

Using Sigma Chemical's **buffer tablets** for phosphate-buffered saline and Tris-buffered saline you can dispense with the need to weigh out compounds (*Reader Service No. 103*). Tableted buffers offer the advantages of convenience of use, accuracy of dosage, and improved stability over powdered forms, says Sigma.

Buffers in tablet form from Sigma.

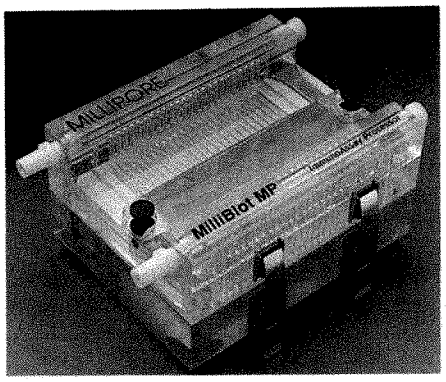


Formulated to exacting specifications for use in immunoassays and enzyme assay procedures, the buffer tablets are available in quantities of 50 and 100 tablets for $19.80 (US) and $33 (US), respectively. Bulk quantities are also available.

Laboratory hardware

Beckman Instruments, Inc. offers its LS 6000SE **liquid scintillation counter** for use in RIA studies (*Reader Service No. 104*). Designed to reduce the number of operating decisions, the system features built-in help screens, preset counting regions,

and quench-correction curve setup parameters. New features include a coincidence monitor for determining non-radioactive events such as chemiluminescence and the Xtalscint option for calculating d.p.m.'s when solid scintillators are used. Beckman says less than 200 µl of sample is needed for c.p.m. analysis. Up to ten user programs can be stored by the machine. The $16,700 (US) LS 6000SE comes with an 80-column printer, sample racks, alphanumeric keypad, high-activity monitor and electrostatic controller.



Where speed and high-throughput of **liquid dispensing** are important considerations, IBG Systems Ltd recommends its Inverness Dispenser (*Reader Service No. 105*). The £5,450 (UK) system can automatically dispense up to 12 different reagents simultaneously into a standard 96-well micotitre plate, in either the 8- or 12-row orientation. The machine takes less than eight seconds to load a microtitre

IBG Systems' 12-reagent dispenser for microtitre plates.

plate with 35 µl per well, says IBG. Magnetic stirrers can keep up to six reagents or cell suspensions evenly mixed when the machine is dispensing. The operator simply primes the system each day or when the reagents are changed and selects the volumes to be dispensed per well, which can be in 5-µl increments from 5 µl to 500 µl. Cross-contamination is avoided because the reagent paths are kept separate. The peristaltic pump has a reverse-control function that allows unused reagents to be returned to their bottles.

Millipore says its new MilliBlot-MP **immunoassay processor** is ideal for screening antibodies against a single antigen (*Reader Service No. 106*). The $1,000 (US) multiple-channel assay device can process 1–24 channels. It uses a standard 7.5 cm × 8.5 cm single-blotted membrane sheet, making it unnecessary to cut and handle individual membrane strips, says Millipore. The device is fitted with a spring-loaded interlock which provides a compression fit and produces distinctly embossed channels on the membrane with a raised reaction surface. This, the company says, gives precise chambering for consistent results from channel to channel and eliminates 'cross-talk'. As little as 100 µl of serum is required per channel; antibodies can be detected from dried blood spots with volumes of 25–100 µl, says Millipore. Conjugate, wash, and chromogen incubations can be carried out within the system, without transferring the membrane.

MilliBlot-MP: Millipore's new immunoassay processor for antibody screening.

Designer labels

AMCA — 7-amino-4-methylcoumarin-3-acetate — is the new **bright-blue fluorophore** from Jackson Immunoresearch Laboratories for use in single and multiple labelling experiments (*Reader Service No. 107*). AMCA is now available conjugated to the company's AffiniPure and Affini-Sorbed antibodies, ChromPure immunoglobulin controls, streptavidin and avidin. The fluorophore absorbs light at 350 nm and fluoresces at 450 nm; this 100-nm Stokes shift produces minimal overlap between excitation and emission spectra, says the company. Jackson Immunoresearch Labs says AMCA's minimal overlap with other fluorophores makes it especially useful in the multiple colour analysis of single sections.

A novel range of **immunodetection reagents** that offer an alternative to streptavidin/avidin detection systems are available from British Bio-technology Ltd (*Reader Service No. 108*). BBL says its Ultra Hapten reagents are based on a high-affinity MAb to biotin and are capable of detecting any biotinylated target molecule. The MAb to biotin is available conjugated to a range of molecules, including alkaline phosphatase, fluorescein, gold, peroxidase, and Texas Red. The company says its reagents overcome the lack of sensitivity and nonspecific binding problems associated with streptavidin and avidin. Stated applications include immunocytochemistry, *in situ* hybridization, Western blotting and electron microscopy.

Immobilization chemistry

Everything you need to prepare **Fab and F(ab')$_2$ fragments** from IgG is now available in a kit from Pierce (*Reader Service No. 109*). Pierce's ImmunoPure Fab preparation kit uses immobilized papain to cleave the IgG; the ImmunoPure F(ab')$_2$ kit uses immobilized pepsin. After cleavage of the IgG, the fragments can be easily separated from the immobilized enzymes, eliminating the need for an ion-exchange separation step, says Pierce. The $295 (US) kits also contain protein A columns and all the buffers required to mop up the Fc fragments and any undigested IgG, leaving purified fragments which are eluted in the void volume.

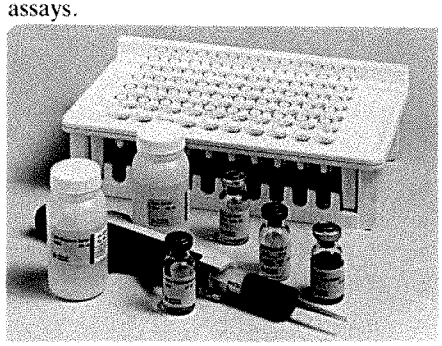
Reader Service No.27

Genex says its **protein G affinity membranes** make IgG purification as easy as filtering a sample (*Reader Service No. 110*). The AbSorbent G affinity discs contain GammaBind G — recombinant protein G bound to a polymer membrane. Samples are loaded by attaching a syringe or pump to the disc; unwanted proteins are washed away and purified IgG is eluted at low pH. Costing between $145–350 (US), the discs are available in three sizes, which Genex says can purify between 0.75 mg and 15 mg of IgG in less than 15 minutes. Genex says the stable ligand attachment and protease-resistance of GammaBind allow the discs to be

Protein G affinity membranes from Genex.

reused. The AbSorbent G discs can be used to purify IgG from dilute hybridoma supernatants and from mouse, human, rat, cow, horse, sheep, rabbit and goat IgG subclasses.



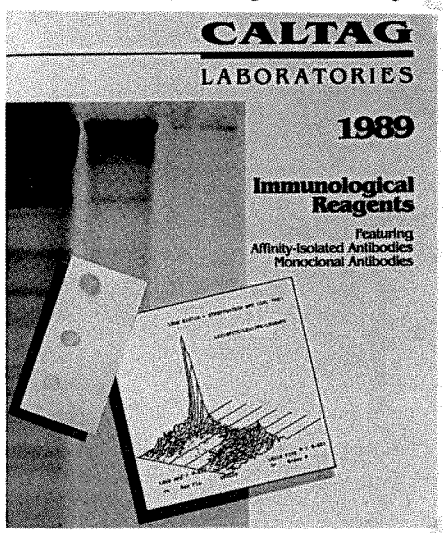
For the rapid purification of IgG, Zymed Laboratories, Inc. recommends its **prepacked protein G columns** (*Reader Service No. 111*). Zymed's $105 (US) 5-cm column contains 1 ml of recombinant-protein G Sepharose 4B gel. The gel contains 2.5 mg of immobilized recombinant protein G, which the company says has a binding capacity of 20–22 mg of human IgG per run. High yields of bound IgG are produced after low-pH elution, says Zymed. The column can be used for the purification of IgG from serum, ascites or supernatant, or for the removal of unwanted IgGs from samples containing other Ig classes. Zymed says the columns can be used for at least 20 runs. For those who prefer to pack their own columns, the company offers recombinant protein G Sepharose gel in 2- and 5-ml quantities, for $120 (US) and $250 (US), respectively.

Affinichrom is the name of a new line of **immunoaffinity chromatography columns** from Kontes Biotechnology (*Reader Service No. 112*). The columns contain non-porous glass beads in sizes from 0.25 mm to 3 mm, coated with avidin, streptavidin, protein A or Concanavalin A. The beads do not exhibit the compression problems and diffusion limitations on flow rate associated with other packing materials, says Kontes. Antibody binding capacity is maximized because the protein-coated column packings bind to the Fc portion of the antibody and maintain proper orientation of the antigen receptor sites. The protein-coated glass beads come prepacked in three sizes of stainless steel HPLC column and one size of glass column, costing between $350 and $1,000 (US). Kontes also offers bulk packings for protein A, avidin and Con A, and a custom column-packing service.

The single-step purification of mouse MAbs from ascites or cell culture supernatant can be achieved using **protein A-agarose** from Boehringer Mannheim (*Reader Service No. 113*). Recombinant protein A is used in the production of protein A-agarose, which Boehringer says is free of the mitogenic staphyloccal enterotoxins that contaminate protein isolated from *Staphylococcus aureus*. Immobilized protein A has a high IgG binding capacity and leakproof stability over a wide range of pH and buffer conditions, says the company. Depending on the elution conditions used, Boehringer says the agarose gel can be used over 30 times. Boehringer also offers recombinant protein G.

Radioimmunoassay kits

Three new **^{125}I RIA kits** are available from Advanced Magnetics, Inc. for the measurement of interleukin-1 alpha, interleukin-1 beta and interleukin-2 (*Reader Service No. 114*). The IL-1 alpha and IL-1 beta kits are based on competitive immunoassays where the analyte in the sample competes with the radioactively labelled analyte for a limited number of antibody sites. The IL-2 kit is a solution-phase RIA based on the 'sandwich' principle, where the IL-2 becomes sandwiched between anti-IL-2 (rabbit) and ^{125}I monoclonal IL-2 tracer. The addition of magnetic particles coupled to goat anti-rabbit IgG antibody followed by magnetic separation or centrifugation produces a pellet which can then be counted in a gamma counter. The interleukin concentration is determined by interpolation from a standard curve. AMI says the IL-1 alpha, IL-1 beta and IL-2 kits have minimal cross-reactivities and can detect 3.0 pg per ml, 0.05 ng per ml and 0.15 units per ml, respectively. The kits have enough reagents to perform 100 assays.



^{125}I RIA kits for measuring interleukin concentration, from AMI.

Collaborative Research, Inc. has a new line of **magnetic lymphokine RIA kits** for the detection and quantitation of IL-1 alpha, IL-1 beta, and IL-2 in culture media or biological fluids (*Reader Service No. 115*). The $415 (US) ^{125}I Magnetic RIA Kits can detect picogram levels of both natural and recombinant lymphokines, says the company. The RIAs use a magnetic second antibody to effect the magnetic bench-top separation of the captured analyte. Results can be obtained in less than a day — half the time required for conventional bioassays, says Collaborative Research. Each kit contains a user's guide and all the reagents, standards and controls to perform 100 assays.

Biochemicals

Caltag Laboratories has a new **catalogue of immunological reagents** that lists over 300 monoclonal and affinity-isolated polyclonal antibodies — both unconjugated and conjugated to enzymes, fluorochromes, biotin and agarose (*Reader Service No. 116*). Caltag offers an expan-

Caltag Laboratories' catalogue of immunological reagents.

ded line of phycoerythrin and allophycocyanin conjugates for use in flow cytometry, new mouse monoclonals to BrdU/IdU, rat immunoglobulins, bacterial alkaline phosphatase and mouse Thy-1.2.

MonoCarb AB's product catalogue features a new range of **MAbs to carbohydrate epitopes** (*Reader Service No. 117*). The antibodies have important applications as a research tool in the fields of serology, oncology, and infectious disease research, but could also have diagnostic and therapeutic uses, says MonoCarb. □

MANAGER, RESEARCH ADMINISTRATION

RESEARCH DIVISION

£22k-£28k+Car

British Bio-technology is a research and development company in health sciences. Utilising both molecular biology and medicinal chemistry techniques, the company aims to bring innovative pharmaceutical products to the human health care market in the 1990's and beyond.

A Career at the Leading Edge of Health Science

With the continued expansion of the company's Research Division and with a number of current research projects progressing into development, we now require a Senior Scientist to work closely with the Director of Research and to assume responsibility for much of the administration in the Research Division.

Aged 30+ and with a PhD in a scientific discipline, you will be an experienced research manager with a life sciences background and a proven track record of running a successful team.

The Division, currently about 100 strong and planned to grow to approximately 150 staff, comprises 3 departments (Medicinal Chemistry, Pharmacology and Molecular Biology), and concentrates on 3 areas of research: vascular disease, inflammation and repair, and virus infections. Many of the research projects involve international collaboration with industrial partners and academic laboratories.
Your responsibilities will include:

- external and internal liaison (e.g. with collaborators consultants and financial institutions)
- maintaining patent records and filing
- organisation of research meetings
- research documentation (e.g. preparation of internal and external reports and planning dossiers)

The successful applicant will receive an excellent salary plus car and the company also offers the following benefits:

- First class pension scheme • Free life assurance
- Share option scheme • Individual health care scheme
- Social Club • 25 days holiday

British Bio-technology Limited

Write with details of your career to date to:

Rod Cook,
Head of Personnel,
British Bio-technology Limited,
Watlington Road, Cowley,
Oxford OX4 5LY
Telephone:(0865)748747

SCOTTISH CROP RESEARCH INSTITUTE
Invergowrie, Dundee DD2 5DA

SCIENTIFIC OFFICER

3 year appointment

TISSUE CULTURE DEPARTMENT

A position exists within the Tissue Culture Department for a Scientific Officer to work on a project concerned with the isolation of genes regulating specific carbohydrate fluxes in potato tubers. The ultimate objective is to transform existing potato cultivars with gene constructs which will modify most fluxes to produce a potato cultivar with characteristics most suited to the potato processing industry.

The position, which is initially for a 3 year period is part of a multinational programme funded by a European Industrial Consortium (ECSA) The appointee will work closely with a senior Molecular Biologist (SSO) in the Tissue Culture Department and will also liaise with two other scientists employed on the same project in the Physiology and Crop Production Department. Candidates with a strong background in laboratory based techniques, particulary those relevant to molecular biology will be preferred The successful candidate may be eligible to register for a higher degree at a local university if suitably qualified.

Salary: Year 1 £9,131, Year 2 £9,646, Year 3 £10,162
Non-contributory superannuation.

Qualifications: First or upper second class honours degree with at least two years post qualifying relevant research experience which may be a course of research and study leading to a PhD degree.

The Institute is an equal opportunities employer.

Curriculum vitae complete with the names and addresses of three referees should be sent to the **Personnel Officer**, by 29th Sept '89 quoting the appropriate reference (Ref. EIC/5/89) (1575)A

UMIST
Manchester Biotechnology Centre

RESEARCH ASSOCIATE

IN YEAST GENOME SEQUENCING

A Post-Doctoral Research Associate is required to join our team participating in a Europe-wide project on yeast genome sequencing. Applicants should have extensive experience of yeast molecular biology and be prepared to perform considerable numbers of DNA sequencing experiments. The post is available for one year.

Salary will be within the scale. £10,458-£16,665 per annum.

For further details and application forms contact. **Professor S G Oliver, Manchester Biotechnology Centre, UMIST, P O Box 88, Manchester M60 1QD.** Tel: 061 200 4221 Reference BIO/110.

An equal opportunity employer. (1584)A

THE UNIVERSITY OF FRIBOURG, SWITZERLAND
INSTITUTE OF ZOOLOGY,
DEPARTMENT OF EXPERIMENTAL EMBRYOLOGY AND TERATOLOGY

POST-DOCTORAL ASSISTANT IN EXPERIMENTAL BIOLOGY

Applications are invited for the above post to join an established team investigating morphogenesis and embryonic differentiation. The research project will involve following themes:

1— differentiation of neural crest cells in vivo and in vitro, in chick and mouse embryos,

2— cell culture and evolutionary processes of their differentiation,

3— role of the NCC in the development of different embryonic tissues, especially bone,

4— study of chimaeras in mouse and bird embryos.

Suitable applicants should have experience in cell culture and biochemistry. The appointments are tenable for at least three years starting on 1st November 1989, or soon thereafter, and are on the University of Fribourg Doctor-Assistant scale (~Srs 50'000.–). Languages are french, english, ev. german.

Informal enquiries and formal applications, including C.V. and names of two referees as soon as possible to

Prof. J. Schowing,
Dept. of exp. Embryology,
Institute of Zoology, Fac. Sciences,
CH-1700 Fribourg, Switzerland.

UCMSM

POST-DOCTORAL RESEARCH FELLOW

to work on cell cycle control in human haemopoietic cells

A three year position is available to work with Dr Shaun Thomas on the function of the cell cycle control gene CDC2Hs in human haemopoietic cells. Experience of cell culture and molecular biology techniques would be an advantage.

The post is funded by the Cancer Research Campaign. Salary on the 1A Scale: £10458-16665 *p.a.* plus £1650 London weighting.

Further details can be obtained from Dr Shaun Thomas or Prof. David Linch on (01) 380 9724.

Applications in duplicate including a *c.v.* and the names of two referees should be sent to:

Dr Shaun Thomas, Ref. PDCRC/89, Department of Haematology, University College and Middlesex School of Medicine, 98 Chenies Mews, London WC1E 6HX.

Affirmative action/equal opportunity employer. (1563)A

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)

RESEARCH TECHNICIAN

The Medical Oncology Unit has a vacancy for a Laboratory Scientific Officer starting immediately.

The post is for 3 years in the first instance, and supported by ICRF to work on Urological Cancer Experience in tissue culture is essential.

Salary: £7,415-£10,148 plus London Weighting.

For further information contact Dr A Nouri, Tel: 01-377 7000 Ext. 3469.

Please send applications including the names of two referees to **Dr R T D Oliver, The London Hospital Oncology Unit, Whitechapel, London E1 2AD.** (1565)A

Scientific Officer

£11,200 – £16,200

The Flow Cytometry group of the Imperial Cancer Research Fund has a vacancy for a Flow Cytometrist Technician. You will be working in Clare Hall Laboratories in South Mimms, Herts.

While experience would be an advantage, full training will be given if necessary. Familarity with the use of computers and general laboratory equipment would be a useful asset.

HNC/Degree in a relevant discipline required.

For further information and application form, please write or telephone the **Recruitment Office, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX.** Telephone 01-242 0200 ext 3357 quoting reference 237/R.

Smoking is actively discouraged. (1594)A

IMPERIAL
CANCER RESEARCH FUND

VIROLOGIST

Pfizer is one of the world's leading research-based pharmaceutical companies Our Sandwich research facility, where a significant part of our anti-infective drug discovery programme is based, currently employs about 750 scientists and support staff. Our present anti-viral strategies include both classical and molecular genetic-based approaches to viral diseases including Herpes and AIDS. We are seeking to expand the virology group and require a Post-doctoral Virologist to join our team.

Candidates should have

- ★ A PhD in Virology
- ★ 1-3 years Post-doctoral experience in virology or Molecular Genetics of viruses
- ★ Research experience with herpes viruses while not essential would be an advantage

We can offer

- ★ The opportunity to develop within a dynamic anti-viral group
- ★ For the right candidate a chance to lead your own team
- ★ A highy competitive salary with merit-related bonuses of up to 20% of salary
- ★ Generous relocation assistance and other benefits including pension, life assurance and private health care schemes
- ★ Flexible working hours and an active sports and social club.

This is a particularly exciting time to join Pfizer as we have a number of new therapeutic agents, discovered and developed at Sandwich, being launched on world markets and others reaching the final stages of their development. We also have a major multi-million pound expansion of our research facilities under construction, demonstrating our long-term commitment to research here at Sandwich and enabling our scientists to look forward with confidence to the 1990's and beyond.

We are located within easy reach of both Canterbury and the Continent and there is a wide range of housing available with prices amongst the lowest in the south-east.

If this advertisement attracts your interest, please write in confidence, giving full details of career-to-date to Mr D O'Callaghan, Pfizer Central Research, Ramsgate Road, Sandwich, Kent CT13 9NJ. Tel: (0304) 616415

Pfizer

(1568)A

TECHNICIANS IN TRANSGENIC SCIENCE

Pharmaceutical Proteins Ltd is a small but expanding Biotechnology Company which is working to produce therapeutically useful proteins in the milk of transgenic mammals This objective requires the co-ordinated efforts of our molecular biologists, who work with small mammals in the development of gene constructs, and our animal scientists who supervise the generation and husbandry of our transgenic sheep flocks

In order to expand our microinjection and animal sciences facilities we require qualified personnel for the following positions

Microinjector — 1

You will have past experience of mouse transgenesis and will liaise with the molecular biology and animal science teams in the planning and implementation of our microinjection programme. You will have a Home Office Licence

Microinjector — 2

You will have had training in molecular biology techniques and will be prepared to acquire microinjection skills You will assist in downstream identification and characterisation of transgenic animals

Animal Technician/Veterinary Nurse

You will have previous experience of assisting with veterinary surgery, ideally with large animals A Home Office Licence would be a definite advantage

The rewards will be attractive for appropriately qualified candidates Location — Edinburgh area Relocation costs in appropriate cases will be met by the Company

Applicants should send a brief CV to
Richard Ackers, Commercial Director,
Pharmaceutical Proteins Ltd , Kings Buildings,
West Mains Road, Edinburgh EH9 3JQ
Tel 031-668 2726 Fax 031-668 3309

PHARMACEUTICAL PROTEINS

(1598)A

ROYAL FREE HOSPITAL
SCHOOL OF MEDICINE
(University of London)

Post Doctoral Research Fellow

An enthusiastic post doctoral scientist with experience in protein chemistry/immunochemistry or related areas required to join a team actively involved in research on cytomegalovirus (previous experience in virology not essential). The team recently discovered that cytomegalovirus binds the host protein B_2-microglobulin and that this allowed the virus to evade and exploit host immune responses. The current project aims to analyse the interaction between CMV membrane proteins and B_2-microglobulin at a molecular level with the long term goal of developing a vaccine against this important human pathogen. The appointee will gain experience in the use of recombinant DNA technology, eukaryotic expression systems and peptide synthesis.

This will be a joint project between the Department of Virology and the newly created Department of Protein & Molecular Biology. Further information can be obtained from Dr Grundy (01-794 0500 ext: 4118/3210). Applications (four copies of curriculum vitae plus names and addresses of two referees) should be sent by 28 September to the **School Office, R.F.H.S.M., Rowland Hill Street, London NW3 2PF.** Please quote reference VIR/PD/30.

(1561)A

ALLIGATOR RIVERS REGION RESEARCH INSTITUTE
Jabiru, Northern Territory, Australia

ASSISTANT RESEARCH DIRECTOR

(Biological Science)

Background: The Supervising Scientist for the Alligator Rivers Region is a statutory office, established by the Environment Protection (Alligator Rivers Region) Act 1978, responsible directly to the Minister for the Arts, Sport, the Environment, Tourism and Territories The Supervising Scientist is responsible for co-ordinating and supervising activities concerned with the protection of the environment, mine workers and members of the public in the Alligator Rivers Region of the Northern Territory from the effects of uranium mining operations. The Act was amended in 1987 to give the Supervising Scientist similar responsibilities for general mining and exploration operations for a Conservation Zone declared within the Region

The Supervising Scientist is also responsible for the research necessary to ensure that standards and protection measures have a firm scientific basis, and for defining practical and effective programs to monitor the environmental impact of mining operations. The focus of these research activities is the Alligator Rivers Region Research Institute which is based in Jabiru East, near the Ranger uranium mine site Currently about forty professional and technical officers in a range of disciplines are employed Research is also undertaken in collaboration with, as well as under contract by, external organisations.

The work of the Research Institute is tactical and problem oriented A multidisciplinary research and development program has been established, components of which currently include aquatic biology, ecotoxicology, plant ecology, environmental radioactivity, environmental modelling, environmental chemistry and geomorphology. Research programs in hydrogeology and hydrogeochemistry are at the planning stage

Jabiru, though a remote township, has a population which currently stands at about 1300. It is located 260 km by highway east of Darwin within the Kakadu National Park (an area included in the World Heritage List) and provides all the community facilities expected in a modern town. Local residents of the Region have available to them pastime activities such as boating, fishing, photography, bird watching, bush-walking and studying Aboriginal art sites

Duties: The Assistant Research Director will direct and carry out research in a relevant specialised area of biological science and assist the Director in the planning and direction of the Institute's biological research programs Preference will be given to applicants with a distinguished research career in freshwater aquatic ecology or ecotoxicology and with some experience in ecosystem risk assessment and the use of ecotoxicological concepts in the regulation of environmental protection The Assistant Research Director may be required to consult with mining companies and liaise with government organisations on scientific and technical matters

Qualifications: Applicants should possess a Ph D or equivalent qualifications and would be expected to have a minimum of 15-20 years postdoctoral experience. A broad based competence in ecological research, including studies of freshwater aquatic ecosystems, is considered important Applicants should also have an international reputation of a high order, with extensive publications in the scientific literature, and several years of scientific management experience, preferably in multidisciplinary environmental research. Ability to maintain and inspire mission-oriented research in a remote locality where tropical extremes are common, will be an important attribute.

Salary: Salary in Australian dollars, depending on qualifications and experience will be determined within the Senior Principal Research Scientist salary range: $56,420-$61,876.

Conditions: In addition to the normal conditions of service in the Australian Public Service, staff located in Jabiru enjoy benefits such as subsidised rental housing, annual leave fare entitlement, 27 days annual leave, remote locality allowance and Zone A tax concessions. Appointment may be either as a permanent officer of the APS or by engagement on a fixed term (3 to 5 years) temporary basis To be eligible for permanent appointment, applicants must be Australian citizens However, if you have not yet obtained citizenship, you can now be appointed to the service on probation with appointment being confirmed when citizenship is granted.

Enquiries: Please write to Ms M. Nguyen, Office of the Supervising Scientist, PO Box 387, Bondi Junction, NSW, Australia, 2022, or FAX 061 02 389 0681 for more detailed information

Applications: Applications including full details of qualifications and experience, personal particulars, publication record, contact telephone, fax or telex numbers, and the names of at least 3 referees should be forwarded to the Office of the Supervising Scientist, PO Box 387, Bondi Junction, NSW 2022, by Friday 27 October 1989

The Office of the Supervising Scientist is actively implementing an equal employment opportunity program aimed at ensuring that fair consideration is given to all applicants.

AUSTRALIA

OFFICE OF THE SUPERVISING SCIENTIST

(W6484)A

THE OPEN UNIVERSITY

FACULTY OF SCIENCE

CHEMICAL HAZARD SPECIALIST

Applications are invited for a Chemical Hazard Specialist to advise the University in all aspects of chemical safety Applicants should have qualifications/experience in both Chemistry, and Safety management. Some experience in computer-based retrieval and PC skills is necessary The post is a University appointment but is likely that the post-holder while having University wide duties will be located within the Chemistry Dept.

The post is permanent and available from a date to be agreed. Previous applicants will be included in the selection process. It may be possible to arrange for this post to be filled on a half-time job share basis, in which case we would be particularly interested in attracting a chemist with research experience.

Salary will be on the grade I scale for Other Related Staff (£9816 – £12381 (bar) – £14169) or the grade II scale (£12879 – £16665 p.a.) depending on qualifications and experience. There will be a two year probationary period

Application forms and further particulars are available from **Mrs B Woodall, (Post 5044/3) Science Faculty, The Open University, Walton Hall, Milton Keynes, MK7 6AA, or telephone Milton Keynes (0908) 653993.** There is a 24 hour answering service on Milton Keynes 653868.

The closing date for applications is 2nd October.

Equal Opportunity is University Policy (1577)A

QUEEN MARY & WESTFIELD COLLEGE

POSTDOCTORAL RESEARCH

School of Biological Sciences

Applications are invited for a 3-year post-doctoral research position to work on an SERC-funded study of the relationship between synaptonemal complex formation and recombination control. The project will involve studies of the progress of synaptonemal complex formation in plants which are mutant either for genes affecting meiosis or for chromosome number and structure. Surface-spreading techniques and electron microscopy will be employed Candidates should preferably be familiar with synaptonemal complex spreading but individuals with experience of chromosome cytology are encouraged to apply

The salary will be scale to £12,708 inclusive and the post is available from 1st October 1989

Application forms are available by telephoning 01 975 5171 (24 hour answerphone service) or write with full CV and the names of two referees to the **Personnel Office, Queen Mary & Westfield College, Mile End Rd, London E1 4NS** no later than 14th October 1989 Please quote job reference number 89/157. Informal enquiries can be made to Dr J S Parker, School of Biological Sciences (01 975 5555 x4116). (1545)A

MEDICAL RESEARCH COUNCIL

NATIONAL INSTITUTE FOR MEDICAL RESEARCH

GENES AND CELLULAR CONTROLS GROUP

LABORATORY OF DEVELOPMENTAL BIOCHEMISTRY

Applications are invited for a three-year post-doctoral appointment to conduct research in association with Dr T J Mohun on the regulation of gene expression during early amphibian embryogenesis. Research concerns the molecular mechanisms underlying tissue-specific gene expression in embryonic mesoderm. Current studies include the role of tissue-specific and ubiquitous transcription factors in terminal differentiation of embryonic muscle cells. The successful candidate will also have opportunities to collaborate with other members of the Laboratory and the Institute.

The salary will be in the range of £12,381-£20,469 plus £1,650 per annum London Allowance. MRC Pension Scheme option.

Applications including a curriculum vitae, list of publications, and the names and addresses of two professional referees, should be sent to **Mr C R Russell, Administrative Manager, National Institute for Medical Research, The Ridgeway, Mill Hill, London NW7 1AA,** not later than 6th October 1989 quoting ref: **0569/GDBM.**

The MRC is an Equal Opportunities Employer. (1552)A

MRC

FACULTY POSITIONS:

DEPARTMENT OF NEUROBIOLOGY AND BEHAVIOR — SUNY STONY BROOK

The Department of Neurobiology and Behavior of SUNY Stony Brook is continuing its search for candidates for tenure-track, state-funded positions in cellular, developmental, molecular and integrative neurobiology, beginning as early as academic year 1989/90 The Department which currently consists of 13 members, is undergoing significant redevelopment and has the resources to grow to 20 members within the next 5 years.

Presently available positions are at the Assistant Professor level although an appointment at the rank of Associate Professor could be considered. Rank and competitive salaries will be commensurate with qualifications. All applicants should have a minimum of 2 years of post-doctoral experience. Candidates will be expected to develop a vigorous independent research program, and as such ample space and start-up funds will be provided Applicants will also be expected to participate in undergraduate, graduate and/or medical school instruction Applicants should submit a curriculum vitae, statement of research interests, and names and addresses of three references to

Dr. Lorne Mendell,
Chairman,
Department of Neurobiology and Behavior,
SUNY Stony Brook,
Stony Brook, NY 11794-5230.

SUNY Stony Brook is an Affirmative Action/Equal Opportunity Educator and Employer. AK 212.

BUSINESS DEVELOPMENT MANAGER

LABORATORY PRODUCTS DIVISION

At least £20k + Car

British Bio-technology is a research and development company in health sciences. Utilising both molecular biology and medicinal chemistry techniques, the company aims to bring innovative pharmaceutical products to the human health care market in the 1990's and beyond.

A Multi-Opportunitiy Enviroment

Reporting to the General Manager, Laboratory Products Division the successful candidate is likely to be aged between 25 and 45 with a first degree in a scientific discipline (Biochemistry, Molecular Biology etc.) and to have commercial experience in a marketing/sales or business development role.

Your main responsibilities will be to identify external sources of new molecular biological and diagnostic products for the company's Laboratory Products business; to negotiate in-licensing and distribution agreements and to manage major contracts. Experience of working in the North American market would be a distinct advantage. A substantial amount of travel will be involved both in the UK and overseas. You will need an outgoing personality with excellent communication skills.

The successful applicant will receive an attractive salary plus car and the company also offers the following benefits:

- First class pension scheme
- Free life assurance
- Share option scheme
- Individual health care scheme
- Social Club
- 25 days holiday

British Bio-technology Limited

Write with details of your career to date to:

Head of Personnel,
British Bio-technology Limited,
Watlington Road, Cowley,
Oxford OX4 5LY
Telephone:(0865)748747

(1589)A

UNIVERSITY OF LEICESTER

POSTDOCTORAL RESEARCH COUNCIL

Two postdoctoral Research Associate positions are available for. (1) an immunologist and (2) a molecular biologist The successful applicants will join a research team investigating the genetic design and evaluation of novel vaccines against parasitic and bacterial diseases.

1 Immunologist The applicant should have a strong background in immunology and an interest in either basic vaccinology, mucosal immunity, or host restriction. The position offers the scope for active collaboration with researchers in Switzerland, Sweden and Italy, and opportunities to work in these participating laboratories will be encouraged

2 Molecular Biologist The applicant should have a strong background in molecular genetics and an interest in the application of protein engineering techniques. The position will entail active collaboration with a major pharmaceutical company

The appointments will have a starting salary of up to £14,169 (position 1) and £12,381 (position 2) per annum, depending on qualifications and experience (RA 1A scale £10,458–£16,665 per annum) Further details may be obtained from Dr T R Hirst (0533–523431)

Applications, including a full c.v. and the names and addresses of three referees, should be sent to **Dr T.R. Hirst, Department of Genetics, University of Leicester, Leicester LE1 7RH** by 1 October 1989. (1498)A

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF BOTANY

MYCOLOGIST/LICHENOLOGIST

A postdoctoral research fellow or an experimental officer is required to work on a major industry-linked venture supported by the Department of Trade and Industry for 2 years commencing November 1989 The project aims to explore lichen-forming fungi as potential sources of exploitable novel natural products such as pharmacophores, enzymes, pigments etc. in collaboration with the Commonwealth Mycological Institute, Xenova Ltd and Biocatalysts Ltd The work will involve isolation and axenic culture of lichen fungi and the development of media to promote spore germination and maximise growth rate. There will be opportunities to participate in lichen collection in the UK and overseas (e.g. South America and Southeast Asia) and also to develop independent lines of research using the fungal collection.

Applicants should have research experience in Mycology or Microbiology The appointment will be on the 1A scale, £10458 to £13527, and applications should be sent as soon as possible to **Dr P. D. Crittenden, Department of Botany, University of Nottingham, Nottingham NG7 2RD,** from whom further details are available. (Fax. 0602 424270) (1583)A

UNIVERSITY OF ZIMBABWE

Applications are invited for the following posts.

ASSOCIATE PROFESSORSHIPS/ SENIOR LECTURESHIPS/LECTURESHIPS

(36839) DEPARTMENT OF BIOLOGICAL SCIENCES

A Biomathematician with a PhD or relevant experience is required to advise and to assist academic staff and postgraduate students with the design, analysis and interpretation of research projects and with mathematical modelling of biological phenomena. The successful applicant will teach courses on these topics, on Basic Statistical Procedure and on Computer usage to Biology students at postgraduate and undergraduate levels Experience in the mathematical analysis and modelling or natural phenomena at levels including the physiological, population and ecological levels will be an advantage.

(36840) DEPARTMENT OF CHEMISTRY (2 posts)

Post A

Candidates should have a relevant PhD degree and lecturing and research experience in Organic Chemistry. Preference will be given to candidates with research interest in synthetic polymer chemistry or physical organic chemistry.

Post B (Applied Chemistry and Technology — BTech Programme at the Harare Polytechnic)

Applicants must have a Masters degree and preferably a PhD in any area of Physical Chemistry. Industrial experience will be an advantage The successful applicant will teach honours degree students and develop research projects relevant to local industrial needs.

(36843) DEPARTMENT OF PHYSICS (2 posts)

Applicants should have at least a good Honours degree in Physics. Preference will be given to holders of a higher degree and to those who have interest in experimental physics in the following areas: modern physics, biophysics, solid state physics, electronics and renewable energy sources. Other areas will also be considered The successful candidates will be expected to participate in teaching and laboratory supervision at all levels and to participate in, or initiate, viable research projects

Salary Scales: Lecturer. Z$19,860-Z$28,176; Senior Lecturer: Z$29,724-Z$31,572; Associate Professor. Z$32,532-Z$33,624. Appointment on the above scales will be according to qualification and experience

Both permanent and short-term contracts are offered Persons who are not Zimbabwean citizens may be appointed only on a short-term contract basis for an initial period of two years. Short-term contracts may be extended

Applicants should quote reference number ASA/15/8/89 and submit six copies of applications giving full personal particulars which should include full name, place and date of birth, qualifications, employment and experience, present salary, date of availability, telephone number and names and addresses of three referees to the **Deputy Registrar (Administration), University of Zimbabwe, P O Box MP 167, Mount Pleasant, Harare, Zimbabwe.** Telegrams. UNIVERSITY; Telex 4-152 ZW. Applicants from outside Zimbabwe should also send a copy to the **Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London, WC1H 0PF, UK,** from whom further details may be obtained

Closing date for receipt of applications is *6 October 1989.*

1/9/89

Circulated to Careers Advisory Officers and Registrars of Universities

EDGEWORTH DAVID CHAIR OF GEOLOGY

(Reference No 31/01)

Applications and expressions of interest are invited for the Edgeworth David Chair of Geology in the Department of Geology and Geophysics. Applicants should have a substantial research background within the discipline of Geology. The successful applicant must be capable of contributing to the teaching program, which covers a range of pure and applied geoscience courses. Fields of current research within the Department include marine sedimentology, palaeontology and stratigraphy, petrophysics and exploration geophysics, petrology, and physical oceanography.

Salary will be at the rate of A$63,919 per annum. Provision is also made for limited private consulting in accordance with the University's regulations Assistance with re-location expenses in Sydney will be provided.

Enquiries about the Department and the Chair should be directed to the Head, Associate Professor D W Emerson in writing or by telephone (02) 693 3244 or by facsimile (02) 692 0184

The University reserves the right not to proceed with any appointment for financial or other reasons.

Applications in triplicate including curriculum vitae, telephone number and fax number, list of publications, and the names, addresses and fax numbers of three referees should be lodged by *17 November 1989* with the Registrar, University of Sydney, NSW 2006, Australia from whom further information should be obtained (Fax +612 692 4316). Further information is also available from Appointments (36869), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF. (W6483)A

RUSH MEDICAL COLLEGE

Postdoctoral positions available immediately to study translational regulation in eukaryotic viruses and growth factors. Recent Ph D with experience in recombinant DNA technology is preferred. Salary commensurate with qualifications. Send curriculum vitae and three letters of reference to

Kailash C. Gupta, Ph.D.
Department of Immunology/ Microbiology
Rush Medical College
1653 West Congress Parkway
Chicago, Illinois 60612

Rush is an equal opportunity-affirmative action employer

(NW4220)A

UNIVERSITY OF NEWCASTLE UPON TYNE

Department of Biochemistry and Genetics

DEMONSTRATOR

Applications are invited for the post of Demonstrator in the Department of Biochemistry and Genetics, tenable for a period three years. Applicants should possess a PhD or equivalent degree and have research experience. The successful candidate will participate in teaching first year undergraduate courses in biochemistry and genetics and the ability to teach some aspects of genetics at a more advanced level would be an advantage Excellent facilities exist for research in a variety of fields.

Salary will be at an appropriate point on the Grade 1 (bar) scale £9,816 - £12,381 per annum according to qualifications and experience.

Further details may be obtained from Professor R H Pain, Department of Biochemistry and Genetics, The University, Newcastle upon Tyne, NE2 4HH (Tel. 091 222 7368) with whom application, (three copies), together with the names and addresses of three referees, should be lodged as soon as possible and not later than 31 October 1989 (1530)A

UNIVERSITY OF EDINBURGH

Department of Genetics

Postdoctoral Research Fellow in Quantitative Genetics

Applications are invited for postdoctoral research positions funded by the AFRC for 3 years from October 1989 to work on the genetics of quantitative traits. Areas of interest to include factors maintaining genetic variability, selection theory and statistical methods for analysis of data from selection experiments and breeding programmes.

Applicants should have appropriate training in population or quantitative genetics and statistics.

The research will be supervised by Professor W G. Hill, FRS, and through a Link Group in collaboration with staff of the AFRC Institute of Animal Physiology and Genetics Research, Edinburgh

The salary will be on the 1A scale commencing between £10,458 and £12,381, depending on age and experience

Applications, including CV and names and addresses of two referees, should be sent to **The Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh** quoting reference number 5705.

Further information can be obtained from Professor Hill (telephone 031-667 1081, ext. 3505). (1560)A

CARDIOVASCULAR & RESPIRATORY PHARMACOLOGISTS

RESEARCH DIVISION

British Bio-technology is a research and development company in health sciences. Utilising both molecular biology and medicinal chemistry techniques, the company aims to bring innovative pharmaceutical products to the human health care market in the 1990's and beyond.

As part of a major new group within Pharmacology you will be members of a team responsible for the detailed in vivo and in vitro pharmacological evaluation of novel biological and chemical agents, in the areas of cardiac, vascular, respiratory and inflammatory diseases.

GROUP LEADER

Reporting to the section head, you will contribute to the formation and running of the group and will play a key role in establishing in vivo models for cardiovascular, respiratory and inflammatory therapeutic targets. You will also initiate new areas of research and interact with multi-disciplinary teams. We are seeking applicants with several years' industrial experience and a record of accomplishment in the development of novel therapeutic agents. Ref:116.

POST GRADUATE PHARMACOLOGISTS

A record of scientific achievement in the field of atherosclerosis and lipid metabolism with experience in animal models of drug action is required for this expanding and important area of interest of the company. Reporting to the section head, you will be responsible for the initiation and evaluation of new therapeutic strategies and models for the testing of novel agents. Ref: 171, 173.

GRADUATE/TECHNICAL RESEARCH ASSISTANTS

We are seeking both experienced and recent graduates to join this expanding team responsible for implementation of the research. As team members you will be expected to gain experience in a number of different techniques involving many aspects of cardiovascular, respiratory and inflammatory disease. You will also have an active role in the development of novel models of disease and will assume responsibility for their day to day management. Ref: 123, 172, 174.

The company offers excellent salaries plus the following benefits:

- First class pension scheme
- Free life assurance
- Share option scheme
- Individual health care scheme
- Social Club
- 25 days holiday

PAKISTAN

Academic appointments for the Ghulam Ishaq Khan (G.I.K.) Institute of Engineering Sciences and Technology, Topi, North Western Frontier Province, Pakistan.

SOPREST (Society for the Promotion of Engineering Sciences & Technology in Pakistan) is a registered Society which is approved as a Charitable Institution by the Government of Pakistan.

Mr. Ghulam Ishaq Khan, President of the Islamic Republic of Pakistan, is one of the 12 Founding Members of the Society and also its President and Chief Executive Officer for life. Other Founding Members include eminent industrialists, scientists and engineers of the Country.

The objective of SOPREST is to establish centres of excellence in Pakistan in the *Private Sector* in the fields of modern engineering and technological education.

The G.I K. Institute is the first centre of excellence proposed to be established by SOPREST in TOPI near the Scenic TARBELA DAM in the NWF Province of Pakistan About 220 acres of land has already been donated by the N.W F.P Government for the Project site and detailed designing work is in progress.

The Institute will, over a period, provide educational and research facilities to at least 400 students every year ranging from the undergraduate levels to Ph.D. in the following disciplines:

1. Metallurgy and Materials Science
2. Mechanical Engineering
3 Computer Science
4. Electronic Engineering
5. Applied Physics and Mathematics

Vacancies under each of these disciplines in the following cadres would need to be filled in the near future by well qualified, internationally reputed and experienced candidates:

— Rector of the Institute
— A Dean for each of the five faculties
— Professors, Assistant Professors and Research Associates

} Salary and terms negotiable

Please apply with full curriculum vitae to:
Mr. H. U. Beg
Executive Director, SOPREST,
4/A, Street No. 41, F-7/1,
Islamabad, PAKISTAN. (W6444)A

Faculty Position
University of Connecticut Health Center

Applications are invited for a tenure track faculty position in the Department of Biostructure and Function. Responsibilities will include teaching of dental, medical and graduate students, student advising, research, and participation in enhancing a strong graduate research training program The position is available at any level Applicants must have a research doctorate, should be firmly committed to a career in teaching and have a strong research program in which excellence and independence have been demonstrated.

Current interests in the Department include macromolecular structure and function, epithelial-mesenchymal interactions in development, the molecular biology of chondrogenesis, skeletal pattern formation and development, transepithelial transport of ions, neural mechanisms in gustation, neuromotor mechanisms of orofacial function, cellular and molecular biology of fibrogenesis, regulation of leukocyte metabolism and secretion, and mechanisms of cell attachment and aggregation during development.

Applications containing a curriculum vitae, a list of publications, three representative publications, a description of research interests, and three named references should be sent to:

Dr. Marvin L. Tanzer, Head, Department of Biostructure and Function, University of Connecticut Health Center, Farmington, CT 06032. Closing date for applications is December 31, 1989.

An Affirmative Action/Equal Opportunity Employer. M/W/H.
(NW4217)A

Cranfield Institute of Technology
BIOTECHNOLOGY CENTRE

LECTURER IN BIOTECHNOLOGY

Applications are invited for the post of Lecturer in the Cranfield Biotechnology Centre, to work in any area of biological research of industrial relevance. This post offers an exciting opportunity to develop an area of expertise within a multidisciplinary research environment. The Centre is largely funded by industry and the appointee will be expected to establish a research activity, financed by industry and government.

Cranfield is a post-graduate research and teaching University and the Biotechnology Centre currently only teaches by research; teaching duties are generally limited to supervision of PhD students.

Applicants should hold a PhD in any relevant discipline plus at least three years' additional experience, preferably in research.

Salary within the range £10,458-£20,469 per annum.

Application forms are available from the **Personnel Department, Cranfield Institute of Technology, Cranfield, Bedford MK43 0AL, telephone Bedford (0234) 750111 extension 3335 (answerphone) quoting reference number 9201K.**

Closing date for applications. 5th October 1989 (1595)A

UNIVERSITY OF OXFORD
Department of Biochemistry

Research Assistant in Physics or Engineering

Applications are invited for the above position tenable for three years in the first instance. The successful applicant will join a multidisciplinary research team investigating the biochemical basis of disease using NMR and other approaches.

The individual will take responsibility for the maintenance and developments in instrumentation to assist the biological and clinical NMR investigations. The candidate will also have the opportunity to participate in several research projects Applicants should hold a degree or equivalent (eg, HND) in the physical or engineering sciences Salary in the range £9816-£14169 pa depending on age and experience.

Applications should be sent to **Professor G K Radda FRS, Department of Biochemistry, Oxford University, South Parks Road, Oxford, OX1 3QU** (telephone 0865 275274) from whom further details can be obtained. (1576)A

THE UNIVERSITY OF LEEDS
DEPARTMENT OF PHYSIOLOGY

PREDOCTORAL RESEARCH ASSISTANT/ POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post for work on the effect of acetylcholine on the electric and mechanical activity and intracellular ion concentration (measured with fluorescent dye of single cardiac myocytes (supported by the British Heart Foundation). A good honours degree and Ph.D. in Physiology/Biology and experience of single cell technique or electrophysiology are required.

Post available from 1st October 1989 for a period of 27 months.

Salary for Predoctoral Research Assistant on the R/A IB Grade with the range (£9876-£12387) or for Postdoctoral Research Fellow on the IA Grade (£10,458-£12875). Candidates for IA should have a PhD or equivalent experience.

Informal enquiries may be made to Dr Mark Boyett (0532 334248).

Application forms and further particulars may be obtained from the **Registrar, University of Leeds, Leeds LS2 9JT** (Tel 0532-33396 direct line) quoting reference number 104/25.

Closing date for applications 6 October 1989. (1585)A

BIOCHEMISTS/CHEMISTS to conduct structural analyses of complex carbohydrates using GC, GC-MS, LC, LC-MS and NMR techniques. Experience with at least one of these techniques required. Two technician and one postdoctoral positions are available The applicant for the technician positions are required to have a B.S. in chemistry or biochemistry, M S is preferred. Salary negotiable depending on experience. Application will be reviewed after October 23, 1989. Send to **Dr. Russell Carlson, Complex Carbohydrate Research Center, The University of Georgia, 220 Riverbend Road, Athens, Georgia 30602 USA.** An AA/EEO institution. (NW4224)A

POSTDOCTORAL FELLOW
Molecular Biology of Growth Factor Receptor

A position is available for research in the area of growth factor receptor biology related to the mechanisms of signal transduction. (For more information see J. Biol. Chem *263* 5319; *263* 5373; *263* 7450, *263* 9462; *263* 5746, *264* 10828; & *264* 13642) strong background in molecular biology or protein chemistry is desirable. Send curriculum vitae and the names of three references to: Dr Roger A. Davis, Department of Biochemistry, University of Massachusetts Medical School, 55 Lake Ave N, Worcester, MA, 01655

The University of Massachusetts is an Equal Opportunity Employer

1839|1989
BOSTON UNIVERSITY SESQUICENTENNIAL

CHAIRMAN
DEPARTMENT OF BIOLOGY
BOSTON UNIVERSITY

Applications and nominations are invited for the position of Chairman of the Department of Biology at Boston University. Candidates must be leaders in their fields of research and be capable of providing aggressive and innovative leadership to the department during an era of growth in the sciences at Boston University.

The Department of Biology includes 31 full-time faculty and 120 graduate students with a broad spectrum of research interests. The University has recently invested over $100 million in the upgrading of science and engineering facilities, including a new Biological Research Laboratory. Strong interactions exist between the faculty in the Department of Biology and other departments and Schools including the College of Engineering and School of Medicine. Close ties to the Woods Hole Marine Biology Laboratory are maintained through the Boston University Marine Program.

Applications, including a curriculum vitae and the names of three or more references, should be sent to:

Lee Makowski
Chairman, Biology Search Committee
Boston University Department of Physics
590 Commonwealth Avenue
Boston, Massachusetts 02215
Fax: 617/353-9393 (NW4215)A

SENIOR NEUROBIOLOGIST/NEUROSCIENTIST

National Institute of Mental Health
Intramural Research Program

The NIMH is accepting applications for a senior neurobiologist/neuroscientist with interests in studying basic brain mechanisms of behavior. Applicants must hold a doctoral degree or equivalent and be interested in joining an established research program involving behavioral neurophysiology, neuroanatomy, neuropsychology, developmental neurobiology, neuroethology and other disciplines. The laboratory facilities are located in a rural setting approximately 30 miles west of the main NIH Bethesda campus near the town of Poolesville, Maryland Researchers in the fields of neurophysiology, neuroanatomy, experimental psychology (including physiological psychology), developmental neurobiology, and related fields in the brain and behavioral sciences are especially encouraged to apply Excellent facilities exist for primate research. The successful candidate should have broad experience and established credentials in the neurosciences. Duties will include scientific leadership and administration of a laboratory, as well as conduct of an internationally-recognized research program. Salary will be commensurate with other NIMH researchers having similar responsibilities, approximately $57,158 to $75,500 plus full Federal benefits. Send C.V., bibliography, a statement of future research directions, and the names of three references to:

Steven M. Paul, M.D.
Acting Director, Intramural Research Program

TENURE TRACT POSITION MOLECULAR BIOLOGY

A vacancy exists at the Assistant or Associate Professor level in the Basic Sciences Division, Faculty of Medicine, Memorial University of Newfoundland. Minimum qualifications required include a Ph.D. and post-doctoral experience in molecular biology. The successful candidate will be expected to establish a vigorous independent research program which could complement on-going programs in gene regulation at the transcriptional and post-transcriptional levels, chromatin organization, molecular cloning of receptor genes for hormones and viruses, and molecular approaches to oncogenesis.

In accordance with Canadian immigration requirements, preference will be given in the first instance to Canadian citizens or landed immigrants. Interested applicants should forward curriculum vitae with an indication of research plans and names of three references to:

Dr. Mary M. Pater, Chairperson
Molecular Biology Search Committee
Faculty of Medicine
Memorial University of Newfoundland
St. John's, Newfoundland, Canada
A1B 3V6

Applications will be received until December 31, 1989 or until the position is filled.

(NW4237)A

Department of Physiology and Biophysics
University of Illinois at Urbana-Champaign

Assistant Professor Protein Crystallography

Applications are invited for a tenure-track position in protein crystallography at the assistant professor level starting August 1990. Applicants are required to have a doctoral degree. The successful candidate is expected to develop a vigorous independent research program and participate in our undergraduate and graduate teaching programs. He/She will join a strong group of molecular biophysicists including two diffractionists as part of the commitment to establish an outstanding program in structural biology. Salary for this 9-month appointment will be commensurate with experience and qualifications. An additional two-month summer salary may be generated from teaching or research sources.

In order to ensure full consideration applications must be received by November 15, 1989 Interviews may be conducted before November 15, 1989, but all applications received by that date will receive full consideration

Applicants should submit a curriculum vitae, a list of publications, a short statement of future research plans, and the names of at least three references to: **Dr. Andrew H.-J. Wang, Chairman, Search Committee, Department of Physiology and Biophysics, 524 Burrill Hall, The University of Illinois at Urbana-Champaign, 407 South Goodwin Avenue, Urbana, IL 61801 (217/244-6637).** The University of Illinois is an Affirmative Action/Equal Opportunity Employer

(NW4242)A

INSTITUTE OF TERRESTRIAL ECOLOGY
MERLEWOOD, CUMBRIA

PLANT ECOLOGIST

The Institute of Terrestrial Ecology has a vacancy for a plant ecologist at its Merlewood Research Station. The successful candidate will be involved in research into responses of plant populations and simple communities to changing climate and increased atmospheric pollution in arctic and upland areas. The duties will involve following the acquisition and allocation of resources in long lived perennial plants in the field, and contributing to the development of mechanistic models of clonal plant growth. The successful candidate will be based at ITE Merlewood and will be involved in collaborative research with Scandinavia and University of Manchester.

Applicants should have obtained or be due to obtain a PhD in an appropriate discipline and should have experience in plant ecophysiology. Experience in computer programming would be an advantage.

The appointment is for a period of 3 years with the possibility of extension. The salary will be in the range of £10,678 to £14,909 per annum, or £13,254 to £18,864 per annum, according to qualifications and experience.

Generous holidays and non-contributory pension scheme.

The Institute of Terrestrial Ecology is a component body of the Natural Environment Research Council.

The Natural Environment Research Council is an equal opportunities employer.

Application forms are available from **Mr D Simms, Station Secretary, Institute of Terrestrial Ecology, Merlewood Research Station, Grange-over-Sands, Cumbria LA11 6JU. Telephone 05395 32264.**

Closing date for completed applications: 9th October 1989. (1592)A

Natural Environment Research Council

SPELMAN COLLEGE

Spelman College invites applications for an **ASSISTANT/ASSOCIATE PROFESSOR OF BIOLOGY.**

The position is available imme diately. Candidates should hol the Ph.D degree and have strong background in molecula biology and/or cell biology. The position involves teaching ar upper-level course in molecula cell biology and an introductory biology course. Curriculum vitae and three letters of recommendation should be sent to: **Ms Jacqueline Pollard, Spelman College, 350 Spelman Lane, S.W. Box 1133, Atlanta, GA 30314-4399.**

Spelman College is an Equa Opportunity Employer.

(NW4222)A

POSTDOCTORAL ASSOCIATES IN BIOCHEMISTRY:

Available immediately to partici pate in projects of isolation o membrane glutamate receptor-ior channel proteins and calcium transport carriers. Studies involve protein isolation, liposome reconstitution, patch clamp and planar bilayer membrane measurements peptide analysis and sequencing Background in protein purification peptide analyses, receptor pharmacology, or membrane bio physics required. Send vitae and 3 letters of reference to **E.K Michaelis, Professor of Pharmacol /Toxicol., Center for Biomedical Research, University of Kansas, 2099 Constant Ave., Lawrence, KS 66046** by September 30, 1989. We are an EEP/AA employer

(NW4223)A

OCEAN SCIENTISTS

The Ocean Sciences Centre, a research unit within the Faculty of Science, Memorial University of Newfoundland, invites applications for two tenure-track faculty positions at the level of Assistant Professor (Research). Research and teaching, primarily at the graduate level, are the primary responsibilities. We will consider persons with a background and achievements in any oceanographic science that complements OSC research in cold oceans, which includes zooplankton ecology, fisheries, oceanography, coldwater aquaculture environments, physiological ecology, geophysics, Quaternary paleo-climatology and paleo-oceanography, and physical oceanography. OSC occupies a 4000m^2 laboratory with full running seawater 6 km north of the University's main campus in St. John's, as well as smaller facilities on campus. Work at sea utilizes OSC's two small boats and major research vessels of the Northwest Atlantic Fisheries Centre and the Bedford Institute of Oceanography. Interested persons should send a resumé, letter of research interests, and the names of three potential referees to:

Richard L. Haedrich, Director, Ocean Sciences Centre, Memorial University of Newfoundland, St. John's, Newfoundland, A1B 5S7, Canada.

Tel: (709) 726-6681; FAX: (709)726-7711; Telemail: NICOS.

In accordance with Canadian Immigration requirements, this advertisement is directed, in the first instance, to Canadian citizens and permanent residents of Canada.

Starting dates: February and June 1990. Application deadline: November 1, 1989. (NW4238)A

UNIVERSITY OF LEICESTER
DEPARTMENTS OF ANATOMY AND BIOCHEMISTRY

POST-DOCTORAL RESEARCH ASSOCIATE

required to work on the expression of genes encoding members of the steroid-receptor super-family Available cDNA sequences will be used as probes to assess the tissue-specificity and timing of expression of the relevant genes by *in situ* hybridisation The position, which is available immediately, is funded by the ICI Central Toxicology Laboratory for a one year period. Candidates with experience of DNA manipulation would be preferred.

Salary on the IA scale, £10,458–£16,665 p a according to experience and qualifications

Please send written applications, including c.v. and the names and addresses of two academic referees to **Professor F. Beck, Department of Anatomy, or Professor W.J Brammar, Department of Biochemistry, University of Leicester, University Road, Leicester LE2 7RH,** as soon as possible. (1550)A

ASSISTANT PROFESSOR/ MOLECULAR BIOLOGY

Applications are invited for a tenure track position in the area of molecular biology. We are seeking candidates with interests in DNA replication, repair, or gene regulation in mammalian systems, but excellent candidates in other areas of molecular biology will be considered. The applicant will be expected to develop a vigorous, independent research program and be involved in the teaching of graduate students. Interested individuals should send a curriculum vitae, reprints of recent papers, a brief description of future research interests and the names and addresses of three referees to: **Dr. Louise Prakash, Head, Molecular Biology Search Committee, Department of Biophysics, University of Rochester School of Medicine, Rochester, NY 14642.** *An Equal Opportunity Employer (M/F).* (NW4212)A

Advance your Career with Applied Biosystems

Applied Biosystems

Join the fastest-growing and most innovative supplier of biotechnology research instruments We are seeking to expand our established team of Technical Support experts who keep ABI at the leading-edge of knowledge in automated synthesis, sequencing and separation of biological important molecules You will join our group of energetic scientists working in fully equipped labs, with automated DNA/Protein Sequencers, DNA/Peptide Synthesisers and a range of separations systems, including HPEC and Capillary Electrophoresis

There are opportunitites for interaction with many research groups of diverse interests because your responsibilities will include the running of customer test samples and advising our users, enabling them to make optimum use of our instrumentation You would also be involved in evaluating new products in the field Our Training Team will require your assistance with customer and sales training You will be required to speak at our scientific seminars throughout Europe and also to promote ABI's scientific presence at International Conferences Therefore, good interpersonal and written communication skills are essential We are offering challenging positions in three areas of customer and sales support Ideally for each job, you should have a recent PhD with practical post-doctoral experience in some of the areas listed

Molecular Biologist:
Various cloning strategies
DNA Sequencing
Southern Blotting
Vector expression systems
Protein purification and isolation

Protein Chemist:
Purification and sequencing of peptides/proteins
Chemical modification of proteins
Synthetic peptide chemistry
Knowledge of Mass Spectrometry would be an advantage

Separations Chemist:
Purifying biological molecules
HPLC and/or Electrophoresis
Analysis of bio-molecules/pharmaceuticals

Attractive salaries and benefits packages, including profit-sharing are offered Relocation expenses would be reimbursed - we are located in a prestigious Science Park in an attractive part of the countryside

If you would like a rewarding career in a biotechnology related field, please send your CV to Brenda Hogan, Personnel Officer, Applied Biosystems Ltd, Kelvin Close, Birchwood Science Park North, Warrington WA3 7PB.
ABI is an equal opportunities employer.

MACROMOLECULAR CRYSTALLOGRAPHERS

Crystallography Laboratory BRI-Basic Research Program
National Cancer Institute-Frederick Cancer Research Facility

Alexander Wlodawer	**Irene Weber**	**Ronald Rubin**
Enzyme Structure	Protein-Nucleic Acid Interactions	Molecular Pharmacology

Scientific positions are available in all three research groups:
Scientist Associates – scientists with demonstrated ability for independent work with at least 2 years of postdoctoral experience
Postdoctoral Fellows – recent PhDs in protein crystallography or other aspects of structural biology
Laboratory Technicians – X-ray and/or protein biochemistry experience

Current projects include:

Antitumor amidohydrolases from 5 bacterial species	Retroviral proteins and oncogene products
Aberrant forms of DNA	Interleukin-8
Transcriptional activators including zinc fingers	Direct phasing of macromolecular structures
Drug-nucleic acid complexes	Analysis of electrostatic interactions
Gamma interferons	Prediction and modeling of structures

Our laboratory offers a stimulating environment for research and state-of-the-art equipment, including two area detectors, several graphics systems, and easy access to a CRAY supercomputer. BRI-Basic Research Program Postdoctoral Fellowships are awarded for 1-3 years with stipends ranging from $24,000 to $30,000/year. Scientist Associate and Laboratory Technician salaries are based on previous experience. Full employee benefits are provided.

To apply, send a curriculum vitae and the names of three references to the investigator(s) of interest, **c/o Dr. Maurice Guss, Executive Officer, BRI-Basic Research Program, NCI-FCRF, P.O. Box B, Bldg. 428, Frederick, MD 21701.** An equal opportunity/affirmative action employer M/F/H/V. (NW4236)A

Associate Director for Education

Applications and nominations are sought for the position of Associate Director of Education to be responsible for the quality and vitality of all Institution education programs and to provide leadership in identifying new educational directions. WHOI is a private research and educational institution that conducts research in ocean related areas of biology, chemistry, engineering, geology, geophysics, physical oceanography and marine policy. Education programs include a joint graduate program with the Massachusetts Institute of Technology, post-doctoral and undergraduate fellowships and traineeships.

In addition to coordinating academic recruiting, enhancing fundraising activities, and allocating existing resources, the Associate Director will be expected to interact at the national and international level on issues of oceanographic/scientific educational policy.

Strong commitment to scholarship and education is essential, demonstrated by a distinguished record in research, teaching, academic leadership and management. PhD in a discipline related to ocean sciences required, with credentials appropriate to a senior scientist appointment.

Nominations and/or applications with curriculum vitae to Dr. Joseph Pedlosky, Chairman, Search Committee, Box 54P, Woods Hole, MA 02543.

Personnel Manager
Box 54P

WOODS HOLE OCEANOGRAPHIC INSTITUTION 1930

WOODS HOLE OCEANOGRAPHIC INSTITUTION

Woods Hole, MA 02543

An Affirmative Action/Equal Opportunity Employer
Women and minorities are encouraged to apply. (NW4235)A

INSTITUTE OF TERRESTRIAL ECOLOGY
BANCHORY
ZOOLOGIST/BOTANIST

Post-doctoral positions are available to work as part of a team on:

REF 1: Factors affecting the selection of individual plants within species by mammalian herbivores.

REF 2: The influence of vegetation pattern on the distribution and foraging strategies and impact of hill sheep and deer.

The work will be carried out from the Institute of Terrestrial Ecology, Banchory in collaboration with the University of Aberdeen, Zoology Department and the Macaulay Land Use Research Institute. It is planned to increase the research team by two further post-doctoral appointments during 1990.

Candidates must have obtained a good honours degree in a biological subject and have at least two years research experience in plant herbivore relationships.

The appointments are for a period of three years and salary will be in the range of £10,678 to £14,909 per annum, dependent upon qualifications and experience.

A driving licence is essential.

Generous leave allowance and non-contributory pension scheme.

The Institute of Terrestrial Ecology is a component body of the Natural Environment Research Council.

NERC is an equal opportunities employer.

Further information and application forms, quoting reference numbers, may be obtained from **Personnel Section, Banchory Research Station, Hill of Brathens, Banchory, Kincardineshire, AB3 4BY, telephone (03302) 3434.**

Closing date for completed application forms is 9th October 1989. (1593)A

Natural Environment Research Council

THE UNIVERSITY OF LEEDS
DEPARTMENT OF COMPUTER STUDIES
RESEARCH FELLOW
(GIS)

Applications are invited for the above 2 year post available from October 1989 to study the theory integrating terrain surface modelling with hierarchical data models in Geographic Informations Systems (GIS) The post is part of the ESRC/NERC sponsored initiative on GIS involving research into the properties and use of optimise quadtrees, dynamic modelling and strategies for accessing location on 3-D surface within the context of human and physical geography.

Applicants should have a sound knowledge of software engineering, at least three years experience and research interests in modelling and simulation. The person appointed will join a lively research group from computer science electronic and electrical engineering and geography.

Informal enquiries should be directed to Dr S. A. Roberts (053. 335458)

The salary will be on the IA scale for Research Fellows (£10458-£16665 according to qualifications and relevant experience.

Further details and an application form may be obtained from the **Registrar, The University, Leeds LS2 9JT.** (Tel: 0532 333969 — direct line) quoting reference No. 48/75 Closing date for applications 9 October 1989. (1574)A

Department of Biological Sciences
TECHNICIAN
(PLANT SCIENCE AND MICROBIOLOGY)
Up to £9,228 (Pay Award Pending)

You will be required to assist in the preparation of practical classes in our Plant Science and Microbiology laboratories, as well as participate in the research activities of the Department.
You should have BTEC or degree qualifications in biological sciences, or have considerable relevant experience. An interest and expertise in plant cell culture would be an advantage.
Ref. No. T7/89

Closing date: Friday 29th September, 1989.

For further details and application form please telephone the Personnel Department on (0203) 838392 or 838451 or write enclosing a large self-addressed envelope to:

Coventry Polytechnic
Priory Street,
Coventry CV1 5FB.
Tel: (0203) 631313.
Fax: (0203) 258597

We welcome applications from women and men regardless of disability, race or marital status. (1587)A

MRC Reproductive Biology Unit and the Department of Surgery, University of Edinburgh
Post Doctoral Scientist

Applications are invited for the above position, which is funded for 3 years by a grant from the Medical Research Council non-directed AIDS programme to Drs R W Kelly, K James and Mr T Hargreave. The project will examine the immunological effects of seminal prostaglandins and their relevance to sexually transmitted disease.

The Postdoctoral candidate will be paid on the MRC Non-Clinical Scientist Grade II scale (£11736-£15372). The candidate should have experience in the field of Biochemistry or Immunology.

For application form and job description please contact Business/Laboratory Manager, MRC Reproductive Biology Unit, Centre for Reproductive Biology, 37 Chalmers Street, Edinburgh EH3 9EW (031 229 2575). Further information from Dr R W Kelly at the same address.

Closing Date: 6th October 1989 (1580)A

UNIVERSITY OF MARYLAND at College Park. The Department of Chemistry and Biochemistry invites applications for two tenure-track faculty positions in the general area of Biochemistry at the level of Assistant Professor. Exceptional candidates at the senior level will also be considered. One position is to be a joint appointment with the University of Maryland Center for Agricultural Biotechnology. Outstanding candidates in all areas of biochemistry will be considered. Applicants for the joint Agricultural Biotechnology position with research interests in plant and insect biochemistry and molecular biology are encouraged to apply. Applicants should submit a curriculum vitae, reprints, a concise statement of research plans and objectives and arrange for three letters of reference to be sent by Nov. 1, 1989 to **Professor Richard N. Armstrong, Chairman, Biochemistry Search Committee, Department of Chemistry and Biochemistry, University of Maryland, College Park, Maryland, 20742.** (NW4218)A

Yale UNIVERSITY

Evolutionary Biology

The Department of Biology is engaged in building an interdisciplinary program in the evolutionary sciences and organismal biology and invites applications for positions at the senior and junior levels. While outstanding scientists working in any area of evolution will be considered, areas of particular interest to our faculty include molecular approaches to population biology or phylogeny, developmental approaches to evolution, evolution of genome organization, and quantitative approaches to evolutionary problems. With building renovations now well underway, we are prepared to make several appointments as soon as possible.

We seek individuals with a strong interdisciplinary inclination, who might profit from interaction with the Department's strong programs in molecular, cell, developmental, and organismal biology, and the Peabody Museum of Natural History.

Send curriculum vitae, description of research interests and names and addresses of at least three references by January 1, 1990 to:

Evolutionary Biology Search Committee, c/o The Chairman, Department of Biology, Yale University, PO Box 6666, New Haven, CT 06511

Yale University is an Affirmative Action/ Equal Opportunity Employer (NW4216)A

ASSISTANT/ASSOCIATE PROFESSOR

The Department of Microbiology and Immunology of the University of Michigan Medical School seeks an immunologist for a tenure-track appointment as Assistant/Associate Professor. The successful applicant will establish an independent research program applying modern molecular/cell biological approaches to the study of the immune response. The position requires active participation in teaching of graduate and medical students Salary support, a well-equipped laboratory and start-up funds are available from departmental resources. Send C.V., a brief statement of research interests and names and addresses of three referees by January 30, 1990 to:

Dr. J. Latham Claflin
Immunology Search Chairman
Department of Microbiology and Immunology
The University of Michigan Medical School
M6643/0620 Medical Science Building II
Ann Arbor, Michigan 48109-0620

The University of Michigan is an equal opportunity Affirmative Action employer (NW4219)A

POSTDOCTORAL TRAINING PROGRAM IN THE CELLULAR/MOLECULAR BIOLOGY OF AGING

Positions are available for postdoctoral trainees (Ph.D. and/or M.D.) to obtain two years of specialized training in the methods and models of research on aging This program is directed by a consortium which includes the University of Pennsylvania/Wistar Institute (Drs. V. Cristofalo, D. Kritchevsky, E. Levine), Temple University (Drs. R. Baserga, N. Duker, A Schwartz), the Medical College of Pennsylvania (Dr. J. Roberts) and Merck Sharp and Dohme Research Laboratories (Drs. M. Bradley and W. Nichols). Research emphases include: cell cycle kinetics/dynamics; growth factor regulatory mechanisms; growth regulatory genes; cellular transformation and immortalization; regulation of gene expression; DNA repair; cytogenetics; nutrition; vascular cell physiology; cardiovascular physiology/pharmacology; and DHEA action in aging and cancer. Applicants must meet NRSA United States citizenship or residency requirements. Address applications (curriculum vitae, three letters of reference and graduate school transcript) to: **Vincent J. Cristofalo, Ph.D., Director, University of Pennsylvania, Center for the Study of Aging, 3615 Chestnut Street, Philadelphia, PA 19104-6006.** (NW4214)A

MRC GROUP IN PROTEIN STRUCTURE AND FUNCTION
University of Alberta, Edmonton

FACULTY POSITION IN X-RAY CRYSTALLOGRAPHY

The Medical Research Council of Canada Group in Protein Structure and Function at the University of Alberta invites applications for a Faculty position immediately available in the Department of Biochemistry. Applicants should have a strong background in protein/macromolecular crystallography and will be expected to develop a research project that will complement and contribute to the overall research efforts in the group. Appointments can be made at any level from Assistant to Full Professor depending upon the qualifications.

The MRC Group in Protein Structure and Function was established in 1974 and has undergone two successful renewals. In addition to X-ray crystallography, the major techniques of physical biochemistry are included in the armament used by the group members for the study of protein systems: hydrodynamic and spectroscopic methods, 2D nuclear magnetic resonance spectroscopy, protein micro-sequencing techniques, solid phase synthesis of peptides, recombinant DNA and protein engineering. The X-ray crystallographic laboratories are supported by excellent facilities, two single crystal diffractometers, two rotating anode generators, an SDMD system area detector with two detectors, two molecular graphics systems. The computing facilities at the University of Alberta are excellent. The University mainframe is an Amdahl 5870 operating under MTS. Access to supercomputing facilities is also possible at the Universities of Toronto (Cray) and Calgary (Cyber 205).

In accordance with Canada Immigration regulations, priority will be given to Canadian citizens and permanent residents. The deadline for the position is November 30, 1989. Applicants should forward curriculum vitae, list of publications and names of three referees as soon as possible to either:

Professor C.M. Kay
Co-Director, MRC Group in Protein Structure and Function
Department of Biochemistry
University of Alberta
Edmonton, Alberta,
Canada T6G 2H7

or

Professor M.N.G. James
Department of Biochemistry
University of Alberta
Edmonton,
Alberta
Canada T6G 2H7

The University of Alberta is committed to the principle of equity in employment. (NW4240)A

BIOLOGICAL CHEMISTRY-ASSISTANT PROFESSOR — UNIVERSITY OF FLORIDA

The Department of Chemistry invites applications for a tenure-track faculty position at the Assistant Professor rank starting in the 1990-91 academic year. Evidence of ability to establish and conduct an innovative and vigorous research and teaching program at the undergraduate and graduate levels is required. We are particularly interested in attracting individuals in molecular biochemistry with research activities in physical measurements, mechanistic studies, or theoretical-computational studies of biochemical systems. This is the first of three faculty positions anticipated to be filled in the next few years in the general area of biological chemistry A successful candidate will be expected to introduce biochemistry into our curriculum both at the undergraduate and graduate levels, and he or she will be affiliated with the University Interdisciplinary Center for Biotechnology Research (ICBR). Applicants should send a complete resume, which includes statements about research plans and teaching interests, and at least three letters of reference to **Professor N. Yngve Ohrn, Chairman of the Search Committee, WM 363, University of Florida, Gainesville, FL 32611.** Deadline for applications is Dec 15, 1989 The University of Florida is an Affirmative Action, Equal Opportunity employer.
(NW4234)A

MRC LABORATORIES
THE GAMBIA

Microbiologist

(Bacteriologist)

You will have overall responsibility for the unit's clinical microbiology service and be expected to make a major contribution to the unit's research programmes into the aetiology of acute respiratory infections in children and into the pattern of secondary infections in patients with HIV 2 infection Considerable experience of clinical microbiology is needed but research experience is not esential. A clinical qualification would be an advantage

Salary, which will be on the MRC's international scale, will be determined by qualifications and experience. The duration of contract that will be offered is negotiable but will be for a minimum of 2 years.

Applications should be submitted to Dr David King, MRC Head Office, 20 Park Crescent, London W1N 4AL from whom further details may be obtained. The closing date for applications is 11th Oct 1989.

UNIVERSITY OF CAMBRIDGE
SCHOOL OF CLINICAL MEDICINE
DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY

A post-doctoral research assistant is required in the Department of Obstetrics and Gynaecology to investigate the role of platelet activating factor (PAF) in human implantation. The successful applicant will determine the relationship between PAF, eicosanoid and inositol phosphate accumulation and intracellular calcium homeostasis The role of embryo-derived PAF in implantation will be studied using conditioned medium and PAF antagonists

The project is funded by a three year grant from the Wellcome Trust awarded to Professor S.K Smith, to whom informal enquiries may be made (Tel. 0223-336871).

Applications in writing giving the names of two referees should be sent to **Mr. R.C. Smith, Principal Assistant, Department of Obstetrics and Gynaecology, Level 2, Rosie Maternity Hospital, Cambridge CB2 2SW.** Closing date for applications 28 September 1989.

The University follows an equal opportunities policy. (1555)A

UNIVERSITY OF SURREY
DEPARTMENT OF MICROBIOLOGY — MOLECULAR BIOLOGY GROUP

Postgraduate Research Officer

Applications are invited for the above position to work with Dr J J McFadden and Dr A Knight (University of Surrey) in conjunction with Dr K Cartwright (Public Health Laboratory, Gloucester), on the molecular biology of the meningococcus and the use of DNA probes as epidemiological tools to study meningococcal disease. Previous experience in molecular biology is desirable but not essential. The appointment is funded by the Meningitis Trust and will be for two years. Salary in the range £9,186-£10,458 pa

Applications in the form of a CV (three copies) and including the names and addresses of two referees should be sent to the **Personnel Office (JLG), University of Surrey, Guildford GU2 5XH** by 6 October 1989 quoting reference **877N.** (1557)A

UNIVERSITY OF CAMBRIDGE
SCHOOL OF CLINICAL MEDICINE
DEPARTMENT OF OBSTETRICS AND GYNAECOLOGY

A post-doctoral research assistant/associate is required to research into the synthesis of colony stimulating factor-1 by human endometrial tissue and the effects of the growth factor on early human trophoblast development. This position would suit a cellular or molecular biologist. The project will involve collaboration with the Institute of Animal Physiology and Genetics Research, Babraham.

The post is supported by a grant from the Medical Research Council for three years in the first instance. Stipend will be according to age, qualifications and experience, on the University scale £11,680-£14,500.

Applications in writing giving the names of two referees should be sent to **Mr. R.C. Smith, Principal Assistant, Department of Obstetrics and Gynaecology, Level 2, Rosie Maternity Hospital, Cambridge CB2 2SW.** Informal enquiries may be made to Professor Smith (Tel: 0223-336871) Closing date for applications 28 September 1989.

The University follows an equal opportunities policy. (1553)A

UNIVERSITY OF LEICESTER

DEPARTMENT OF BIOCHEMISTRY

RESEARCH TECHNICIAN (Grade C) required to join a group carrying out research on the selection of alternative splice sites in eukaryotic pre-mRNA. The work will involve molecular biology and responsibility for setting up and supervising oocyte microinjection methods, for which training will be provided. Applicants should have three years relevant experience and a minimum of ONC or equivalent. Applications are also welcome from recent graduates with relevant degrees for appointment as Graduate Trainees for an initial twelve months This post is tenable for a three year period.

Salary on the Technicians Grade C scale £7,479 to £8,645 a year; Graduate Trainees will receive an initial £6,939 a year.

Applications, including CV and the names of two referees, should be sent to **Dr Ian Eperon, Department of Biochemistry, University of Leicester, Leicester LE1 7RH** (telephone 0533–523482) as soon as possible. (1562)A

INSTITUTE OF PSYCHIATRY
(University of London)

POSTGRADUATE MOLECULAR BIOLOGIST

A post is available as part of a group investigating genetic influences in mental illness. Work will involve genetic linkage analysis using polymorphic DNA markers as well as long-range genetic mapping using pulsed-field gel electrophoresis. Experience in molecular genetic techniques (DNA extraction, Southern blotting, PFGE, DNA cloning) an advantage but not essential.

Salary in the range £9816–£10458 pa + £1650 London Weighting.

Further details may be obtained from Dr Steve Whatley, Department of Neuroscience (Tel: 01-703 5411 ext. 3258).

Applications in the form of curriculum vitae and the names of two referees should be sent to the **Assistant Secretary, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF** quoting ref SW/. Closing date: 6th October 1989. (1546)A

REGULATION OF MITOCHONDRIAL BIOGENESIS AND FUNCTION IN PLANTS

DEPARTMENT OF PLANT SCIENCES UNIVERSITY OF OXFORD

POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for a postdoctoral research fellow to join a group led by Professor C.J. Leaver FRS, working on the regulation of mitochondrial biogenesis and function in higher plants in collaboration with Professor D.A. Walker FRS (Sheffield University) and Dr. J.H. Bryce (Heriot Watt University. The post is funded by the AFRC Plant Molecular Biology initiative and is available for three years with a start date at any time between 1st October 1989 and 1st March 1990. The starting salary will be on the RA 1A scale (£10,458–£12,381 at age 26–£16,665) depending on age and experience.

Applicants should have or expect to obtain a PhD with a background in biochemistry, cell biology or molecular biology and although experience of working with plants is desirable it is not essential.

Applications including a c.v and the names and addresses of two referees should be sent to the **Administrator, Department of Plant Sciences, University of Oxford, South Parks Road, Oxford OX1 3RA.** Further information may be obtained by telephoning Professor Leaver on 031–667–1081 Ext. 3304. (1494)A

UNIVERSITY COLLEGE AND MIDDLESEX SCHOOL OF MEDICINE
ACADEMIC DEPARTMENT OF PSYCHIATRY AND MEDICAL MOLECULAR BIOLOGY UNIT

RESEARCH ASSISTANT and SCIENTIFIC OFFICER in HUMAN MOLECULAR GENETICS

To join a research group working on the molecular genetics of mental illness. One position (Scientific officer, biochemistry, £9522-11,636 p a.) is funded by the MRC human genome mapping programme for the development of research to identify coding sequences by the use of oligonucleotide hybridisation. The position is for two years in the first instance and is suitable for M.Phil./Ph D. registration. The second position is for a pre or postdoctoral research assistant (1A/1B scale) to join an on-going project for 14 months studying gene expression changes induced by psychotropic drugs and is also suitable for higher degree registration. For further information ring or write as soon as possible to Dr. H. Gurling, Tel 01-380-9474/9475, or Dr. G. Melmer on 01-636-8333 ext 3073 at the **Academic Department of Psychiatry, University College and Middlesex School of Medicine, Riding House Street, London W1P 7PN.** Applicants should send a full C.V. and the names of at least two referees. At the CHRISTIAN-ALBRECHTS-UNIVERSITY at KIEL (FRG)

a position as

FULL-PROFESSOR (C 4) in Polar Ecology

is established in the

INSTITUTE OF POLAR ECOLOGY

beginning with 1 April 1991

Applicants should bear a german degree of "habilitation" or an equivalent qualification. They have to be experienced in research and teaching in ecology of the polar regions (e g theoretical ecology and physiological ecology). A more extensive participation in teaching of ecology is required.

At present in the Institute of Polar Ecology a marine-biological (Professor HEMPEL) as well as a terrestrial-botanical (Professor KAPPEN) working group is established.

The University of Kiel has a broad interest in ecology, ecophysiology and all disciplines or marine research A special research programme (Sonderforschungsbereich) for "sedimentation in the Greenland-Norwegian Sea" exists and there is a close cooperation with the Alfred-Wegener-Institute for Polar and Marine Research.

Women are especially invited to apply.

Applications with supporting documents (curriculum vitae, certifications, etc) and a short summary of perspectives should be sent before 1 December 1989 to the **Dekan der Mathematisch-Naturwissenschaftlichen Fakultat der Christian-Albrechts-Universitat zu Kiel, Olshausenstr. 40, D-2300 Kiel 1, Federal Republic of Germany** (W6492)A

DEPARTMENT OF EARTH SCIENCES

POSTDOCTORAL SENIOR RESEARCH ASSISTANT/RESERCH ASSOCIATE

Tenable from 1st January 1990 at an initial salary within the range £10,458-£13,527 per annum

To work with Dr S Flint and Professor T Elliott on a two year project sponsored by Shell Expro investigating the 3-D geometry/architecture of stacked wave-dominated deltaic sand bodies and the distribution of internal heterogeneities Extensive fieldwork periods in southern Utah will include detailed 3-D facies and sequential analysis of outcrops and core/wireline log data from adjacent wells The project will integrate with ongoing outcrop/reservoir modelling studies at Liverpool and Shell Research, Rijswijk, where the appointee will spend some work and, if necessary, training periods Please state your reasons for applying Informal enquiries to Dr S Flint (051-794 5168)

Quote Ref RV/499/N
Closing date 5 October 1989

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL SENIOR RESEARCH ASSISTANT

Salary in the range £10,458-£12,879 per annum

To join an active and well-funded research group, investigating the mechanisms of oestrogen and antioestrogen responses of human breast cancer cells The regulation of specific gene expression is being studied and experience of recombinant DNA techniques would be an advantage

Informal enquiries to Dr C D Green (051-794 4365)

Quote Ref RV/498/N
Closing date 22 September 1989

DEPARTMENT OF MEDICINE

RESEARCH ASSISTANT

Tenable from October 1989 at an initial salary within the range £9,816-£11,088 per annum

To work on the role of hypothalamic regulatory peptides in anorexia and cachexia associated with malignancy Candidates should hold a good honours degree in biological sciences Funded by the Cancer Research Campaign for one year in the first instance, with the possibility of renewal for up to three years The work involves microdissection and related techniques, radioimmunoassay, receptor studies and molecular biological methods and will investigate the effects of peptide analogues on appetite and energy balance The project is suitable for a Ph D thesis Informal enquiries to Dr G Williams (051-709 0141, bleep 410)

University of Leicester

BIOCHEMIST/ENZYMOLOGIST

Applications are invited for a postdoctoral research associate to join an interdisciplinary group working on structural and mechanistic studies of chalcone and stilbene synthases in higher plants. The project which will involve enzyme isolation, protein structural and enzyme substrate studies, forms part of a collaborative study with the Max Planck Institute für Zuchtungsforschung, Cologne (Prof. K Hahlbrock) and the Institut für Biologie, University of Freiburg (Profs. H. Grisebach and J. Schröder). Parts of the work will be carried out at these institutes.

The post which is part of the AFRC's coordinated programme in plant molecular biology is available immediately and is funded for 3 years on the RAIA scale (£10,458–£16,665). Applications including a c.v. and the names of two referees should be sent to: **Professor T J Simpson, Department of Chemistry, University of Leicester, University Road, Leicester LE1 7RH** (tel. 0533–522107) from whom further details may be obtained.

(1551)A

HUMAN FRONTIER SCIENCE PROGRAM (HFSP)

THE NEW INTERNATIONAL PROGRAM STARTS NOW

BACKGROUND

The Human Frontier Science Program (HFSP) is an international program which was proposed by the Japanese Government at the Venice Economic Summit Meeting in 1987. Over the ensuing two years, momentum has built up behind the HFSP. Discussions took place at the Toronto Economic Summit Meeting (June 1988) and at the meetings of eminent scientists and experts from the Economic Summit member countries and the Commission of the European Communities.

GUIDING PRINCIPLES OF THE HUMAN FRONTIER SCIENCE PROGRAM

The Human Frontier Science Program is a project aimed at promoting, through international cooperation, basic research focused on the elucidation of the sophisticated and complex mechanisms of living organisms, with the research results being made available to all mankind.

It is expected that the elucidation of such biological functions, through leading-edge science and technology, will be a great contribution to the intellectual vitality which underlies the history of the natural sciences. Seeds will be sown for the growth of future scientific and technological development, and will form the dynamic behind the promotion of a wide variety of kinds of research. Envisioned is the creation of a future science and technology system thoroughly inspired by a respect for a more rigorous and widespread harmony between nature and mankind.

The Human Frontier Science Program, addressing issues common to all humanity, aims to progress by the encouragement and distillation of scientific knowledge and wisdom on a global scale. An important prerequisite to extending the boundaries of scientific knowledge is the existence of favorable opportunities for the bringing together of outstanding scientific wisdom and different scientific ideas: and further, that their advocates are able to cooperate in a variety of joint projects. Importance is attached to the training and support of young researchers, who are expected to play an important role in originating and pursuing creative research.

To take advantage of the full potential for important findings arising out of an interdisciplinary approach, it is the goal of the HFSP to involve the world's outstanding scientists from many fields. To this end, the HFSP sees the necessity of a trans-national system under which scientists from many different disciplines and countries can pool their insights, participate in joint research and enjoy a smooth exchange of human resources and information.

It is the intention of the Program that research results obtained through such cooperation will be made available to all countries for use in promoting the well-being of the whole of humankind through publication in scientific literature and other appropriate media. Furthermore, a key guiding spirit behind the HFSP promotion of basic research will be consideration of the ethical implications arising from the results of that research. It is the goal of this Program to encourage research that adds to the quality of life and the dignity of human-beings, improves the environment and furthers international harmony.

Invitation for Applications

Research Grants/Fellowships/Workshops

Research Areas of the HFSP:

(A) Basic research for the elucidation of brain functions

1. Perception and Cognition
2. Movement and Behaviour
3. Memory and Learning
4. Language and Thinking

(B) Basic research for the elucidation of biological functions through molecular level approaches

1. Expression of Genetic Information
2. Morphogenesis
3. Molecular Recognition and Responses
4. Energy Conversion

Research grants: Grants for basic research carried out by international joint research teams represented by principal researchers from one of the eligible countries*.

Fellowships: Fellowships for researchers from the eligible countries who wish to do research in foreign countries, or for researchers outside the eligible countries who wish to do research in one of the eligible countries.

Workshops: Subsidies for international workshops organized by researchers from the eligible countries.

* The eligible countries for fiscal year 1989 are Canada, France, F.R.G., Italy, Japan, U.K., and U.S.A.. Researchers in non-summit EC member countries may apply through the Commission of the EC on equal terms with the researchers in the eligible countries. (Details in the guidebook)

Prospective number of awards and duration of each activity for fiscal year 1989:

Research Grants	~	20	3 years
Long-term Fellowships	~	100	3 months – 2 years
Short-term Fellowships	~	50	2 weeks – 3 months
Workshops	~	10	----

Application Deadline: November 15, 1989
In fiscal year 1989, awardees will be determined by March 31, 1990, after the review procedures are completed by the organization to implement the HFSP.

Further information:
Until the organization is established in Strasbourg (France) this fall, the Task Force on the HFSP of the Japanese Government will undertake preparatory activities on behalf of the organization.

Guidebooks and Application Forms may be obtained upon request from the address given below. (Please indicate which program activity [Research Grant/ Fellowship/Workshop] you are interested in.) (W6485)A

HFSP

UNIVERSITY OF OXFORD

In association with Lincoln College

UNIVERSITY LECTURESHIP IN EXPERIMENTAL PATHOLOGY

Applications are invited for the above post tenable from 1 October 1990. Candidates are expected to have an outstanding research record in some branch of Cellular Biology; the successful candidate will be expected to contribute to pre-clinical medical teaching. Stipend according to age on the scale £10,458-£21,852 The successful candidate may be offered a tutorial fellowship at Lincoln College with appropriate teaching responsibility Further details may be obtained from **Professor H Harris, FRS, Sir William Dunn School of Pathology, South Parks Road, Oxford, OX1 3RE,** to whom applications (nine type copies or one from overseas applicants) with full curriculum vitae and summary of research interests should be sent by 10 November 1989. Applicants are asked to arrange for three references to be sent direct to Professor Harris by the same date (1581)A

The University is an Equal Opportunity Employer

Faculty Position, Microbiology UCLA

The Department of Microbiology, College of Letters and Science, University of California, Los Angeles has a tenure-track position available for a molecular biologist The primary areas of recruitment interest are, 1) molecular genetics of yeast, 2) molecular aspects of archaebacteria A Ph D or equivalent as well as several years of post-doctoral experience in microbiology, molecular biology, or a related field is required, with evidence of research accomplishments and teaching abilities. The individual selected will be expected to establish a strong research program as well as participate in undergraduate and graduate student teaching. Title and salary (nationally competitive) are commensurate with qualifications and experience with preference for an entry level position. Applicants should send a letter of application, curriculum vitae, summary of research interest, relevant publications, and the names and addresses of three references to **Dr. Virginia L. Miller, Dept. of Microbiology, UCLA, 405 Hilgard Ave., Los Angeles, CA, 90024.** Deadline for applications is December 15th, 1989. UCLA is an equal opportunity employer — women and minorities are encouraged to apply. (NW4231)A

UNIVERSITY OF GLASGOW
Department of Veterinary Pathology
POST-DOCTORAL IMMUNOLOGISTS

Two positions are available for post-doctoral immunologists to join a group investigating the immune response to the feline retroviruses, feline leukaemia virus (FeLV) and feline immunodeficiency virus (FIV). The aim of the group is to define the cellular immune responses to each virus and apply this knowledge to vaccination and immunotherapy of these and related retroviruses including HIV in man. Candidates should have a background in experimental immunology, and experience in cellular responses to viral infections would be an advantage

The department has excellent modern facilities for work in immunology, virology and molecular biology. Each position is for a period of 3 years beginning in October, 1989. The FeLV project is funded by the Leukaemia Research Fund and the FIV project by the Wellcome Trust. Salaries are on the 1A scale for Research and Analogous Staff (starting salary £10,458).

Applications, including a CV, should be sent to **Professor Oswald Jarrett, University of Glasgow, Department of Veterinary Pathology, Bearsden, Glasgow G61 1QH** (Telephone: 041-330 5773; Fax: 041-330 5602 from whom further information may be obtained. (1572)A

Postdoctoral Position for Electronmicroscopist

Work with interdisciplinary group pursuing basic mechanism of mechanical transduction in membranes. Familiarity with patch-clamp, cytoskeleton, immunocytochemistry, cryo-techniques and electromicroscopy essential Salary $18,000 to $23,000 annually Send CV and references to. **Dr. F. Sachs, Biophysics, SUNY Medical School, 105 Parker Hall, Buffalo, NY 14214.** To be received by 9/30/89 *AA/EEO* (NW4227)A

UNIVERSITY OF LEICESTER
DEPARTMENT OF CHEMISTRY
GRADUATE RESEARCH ASSISTANT

Applications are invited for a graduate research assistant to join an interdisciplinary group working on structural and mechanistic studies of chalcone and stilbene synthase enzymes in higher plants. The position is suitable for a graduate in Chemistry or related discipline and will involve the synthesis of isotopically labelled substrates for mechanistic studies and substrate analogues carrying affinity labelling groups for protein structural studies The project forms part of a collaborative study with the Max Planck Institute für Zuchtungsforschung, Cologne (Prof. K Hahlbrock) and the Institut fur Biologie, University of Freiburg (Profs. H Grisebach and J Schröder). Parts of the work will be carried out at these institutes.

The post is funded for 3 years on the RAIB scale (£9,816-12,381). Suitably qualified candidates may be able to register for a higher degree Applications including a c.v. and the names of two referees should be sent to: **Professor T J Simpson, Department of Chemistry, University of Leicester, University Road, Leicester LE1 7RH** (tel. 0533-522107), from whom further details may be obtained. (1558)A

ANATOMIST

The Department of Anatomy, University of Saskatchewan, College of Medicine, invites applications for a faculty appointment at the rank of assistant professor. Applicants must have postdoctoral experience with a strong research program in anatomical sciences, however, research in functional anatomy is preferred. The successful candidate will be responsible for teaching gross anatomy to physical therapy students. In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents.

Application, including curriculum vitae, names of three referees, and an outline of proposed research and previous teaching experience should be submitted by December 1, 1989 to·

Dr. G. D. Burkholder
Department of Anatomy
College of Medicine
University of Saskatchewan
Saskatoon, Saskatchewan
Canada, S7N 0W0

(NW4239)A

THE UNIVERSITY OF SYDNEY
Australia

SENIOR LECTURER/ LECTURER IN PHARMACOLOGY

Applications are invited from su ably qualified Science, Pharmac Medical or Veterinary Scien graduates for 2 lectureship po tions. The Department would w come new research initiatives cell biology, immunopharmac logy, pharmacokinetics or veteri ary pharmacology, however pe sons with demonstrated ability any area of modern pharmacol gical research and the ability teach in several areas of pharm cology are encouraged to apply is envisaged that the successf applicants will take up the appointments in February 199 The appointments have the pote tial to lead to tenure and as suc would usually be probationary-f three years. Enquiries to Profess Graham Johnston (02) 692 240 Fax (02) 692 3868

Salary: Senior Lectur A$41,459-$48,086 per annur Lecturer A$31,259-$40622 p annum. Clinical loading A$11,366 is available to suitab qualified appointees

Applications, quoting referen no 34/03 including curriculu vitae, list of publications and t names, addresses and FAX nur bers of three referees, to t Registrar, Staff Office, Universi of Sydney, NSW 2006, Austral by *29 September 1989* (FA +612 692 4316). Further gener information is available fro Appointments (36870), Associ tion of Commonwealth Univers ties, 36 Gordon Square, Londo WC1H 0PF.

The University reserves t right not to proceed with a appointment for financial or oth reasons (W6488)A

CHARING CROSS AND WESTMINSTER MEDICAL SCHOOL AND UNIVERSITY COLLEGE LONDON

POSTDOCTORAL RESEARCH ASSOCIATE

To investigate the power and energy changes in fish muscle during contractions which simulate those during swimming. The work will be done in the laboratories of Dr N. A. Curtin (CXWMS) and Prof R. C. Woledge (UCL). This SERC funded post is for 3 years, starting on January 1st 1990. Previous experience in muscle physiology is an advantage but is not essential as training will be given.

Further information can be obtained from either Dr Curtin (01-846 7287) or Prof Woledge (01-380 7133). Applications including CV and names of two referees should be submitted to **Prof R. Woledge, Physiology Department, University College, Gower Street, London WC1E 6BT,** by October 15th.

Equal Opportunity Employer. (1478)A

INSTITUTE OF CHILD HEALTH

University of London

Applications are invited for two Cancer Research Campaign-funded positions, one postdoctoral (£14,529–£15,819 inclusive), and one MLSO 1 (£10,650–£11,415 inclusive) in the Department of Haematology/ Oncology to study the molecular basis of genetic changes in the childhood tumour rhabdomyosarcoma. The successful candidates will be expected to have experience in either molecular biology or somatic cell genetics.

The project is designed specifically to isolate junction fragments associated with chromosome rearrangements in these tumours. Considerable experience of the necessary techniques is already available in the Department.

Informal inquiries can be made to **Dr. Chris Mitchell (Department of Haematology/Oncology, Institute of Child Health, Guilford Street, London WC1N 1EH,** 01–242–9789, extension 2317), to whom a full c.v. with two referees should be sent as soon as possible. (1554)A

ROYAL POSTGRADUATE MEDICAL SCHOOL (University of London)

INSTITUTE OF OBSTETRICS AND GYNAECOLOGY

POST-DOCTORAL RESEARCH OFFICER

Applications are invited from post-doctoral scientists for the above post. The successful applicant will join an on-going programme aimed at elucidating the roles of platelets and lymphocytes in the development of pre-eclamptic toxaema or hypertension during human pregnancy. Applicants should have some experience in one of the following fields: platelet function, platelet membrane analysis or arachidonic acid metabolism and radio-immunoassay.

Salary will be on scale 1A, £10458-£16665 plus £1650 London Allowance a year, commencing as soon as possible until the end of 1990.

Application forms and further particulars are available from the **Personnel Office, Royal Postgraduate Medical School, Du Cane Road, London W12 0NN, (tel: 01-740 3204) quoting ref: AGVD.** (1548)A

Station Biologique de la Tour du Valat

SCIENTIFIC DIRECTOR

The Station Biologique de la Tour du Valat is an ecological research station belonging to a foundation and located in the Camargue, on the Mediterranean coast of France. It has a research staff of about 12 senior scientists and up to 20 assistants. It is owner of a nature reserve of 1700 ha.

The station conducts a research programme on wetland ecology investigating ecological parameters and processes of importance for the diversity of wildlife. Main efforts are directed towards habitat use of birds (8 species of heron, flamingo and various other water birds), fish and grazing mammals, other investigations concern water plants and their response to various regimes of water, salinity and grazing. A programme on geochemistry and nutrients is also under way. This research has been mainly conducted in the Camargue but has increasingly included other mediterranean wetlands. Acquired knowledge has been used for management of wetlands in the Camargue.

The board of the foundation has decided that the research programme should continue and address increasingly key problems of mediterranean-wide scope, and that the acquired knowledge should be increasingly used to support conservation and management of mediterranean wetlands.

A scientific director is sought to design a programme according to these guidelines and to direct the research team of the station for implementing this programme.

Candidates should have considerable experience in ecological research in wetlands, as well as in wetland conservation and management. They should command respect and confidence, be able to enhance teamwork and to direct researchers towards accomplishment of agreed goals.

They should have a good command of English and French language. The preferred age bracket is 35 to 45 years.

Remuneration will depend on qualification of the candidate.

Applications and requests should be addressed to:

Dr. L. Hoffmann, president, Fondation Tour du Valat Le Sambuc, F-13200 Aries

(W6493)A

SIMON FRASER UNIVERSITY

DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited for two tenure-track positions at the Assistant Professor level, one in CELL BIOLOGY, the other in MICROBIOLOGY. The successful candidates will participate in undergraduate teaching and graduate training in their respective disciplines, and establish independent and vigorous research programs. The appointments are subject to final budget approval.

Applicants should clearly state for which position they are applying. They should submit their curriculum vitae, representative recent publications, a statement of their research interests, and have three letters of reference sent to:

Dr. L.M. Srivastava, Chair
Department of Biological Sciences
Simon Fraser University
Burnaby, B.C. Canada
V5A 1S6

Simon Fraser University offers equal employment opportunities to qualified applicants. While all eligible scientists are encouraged to apply, this advertisement is particularly directed to citizens and permanent residents of Canada.

CLOSING DATE: NOVEMBER 15, 1989. (NW4213)A

QUEEN MARY & WESTFIELD COLLEGE

University of London

LECTURER IN NEUROBIOLOGY

Department of Biological Sciences

Applications are invited for a Lectureship in Neurobiology. The successful applicant will be expected to undertake research in his/her field and to teach in the appropriate undergraduate/ postgraduate programmes. Some interest in and experience of Pharmacology would be advantageous.

Salary will be on the Lecturer A scale, £12,108 to £17,022 inclusive Further details and application forms are obtainable by telephoning 01 975 5171 (24 hour answerphone service) or send full CV with the names of two referees to the **Personnel Office, Queen Mary & Westfield College, Mile End Rd, London E1 4NS** no later than 28th September 1989. (1547)A

THE INSTITUTE FOR ADVANCED STUDY

Will have several openings for members in theoretical physics and astrophysics for the academic year 1990-91. The positions are at a postdoctoral or higher level and applicants will be selected on the basis of their ability to do research in the areas of astrophysics, elementary particle physics, mathematical physics, general relativity and statistical mechanics. Preference is given to candidates who have received their Ph.D. within the last year or two. Postdoctoral members frequently collaborate with each other, with faculty members at the Institute of Princeton University, and with researchers at other institutions. Appointments are usually for two years and support is typically full salary for postdoctorals and half salary for more senior persons. Women and minorities are encouraged to apply. For more information write to **Michelle Sage, School Administrative Officer, School of Natural Sciences, Institute for Advanced Study, Princeton, New Jersey 08540.** Applications should be received by December 15, 1989 (NW4210)A

Postdoctoral — Caltech

Postdoctoral research associate position available to investigate specificity determinants for enzyme catalyzed protein modification. Experience in protein purification, radioisotope handling and enzyme kinetics desired. Send CV, description of relevant experience and 3 references to **Dr. Barbara Imperiali, Chemistry, 164–30, Caltech, Pasadena, CA 91125. (FAX: 818-568-8824).** *Caltech is an AA/EO employer; women and minorities are encouraged to apply.* (NW4241)A

UNIVERSITY OF CAMBRIDGE

POSTDOCTORAL RESEARCH ASSOCIATE

to work on the history of sedimentation on deep sea sediment drifts in the north-east Atlantic, under the direction of Professor I. N. McCave. Selected periods in the last 5 million years of Atlantic Ocean history will be studied using a combination of sedimentology, micropalaeontology, chemistry and O/C isotopic analysis. Recent Ph.D.s in these fields are encouraged to apply. The project will involve sampling of Ocean Drilling Project Cores in New York and work in the laboratories of Professor McCave, Dr. N. J. Shackleton and Dr. H. Elderfield in Cambridge.

Salary scale £10,458-£15,372.

Applications, including c.v. (4 copies), should be sent to the **Administrator, Department of Earth Sciences, Downing Street, Cambridge CB2 3EQ** by *Monday, 16 October, 1989.* (1573)A

UNIVERSITY OF ABERDEEN

DEPARTMENT OF GENETICS AND MICROBIOLOGY

POSTDOCTORAL/POSTGRADUATE ASSISTANT IN MOLECULAR IMMUNOLOGY

Applications are invited for the above post for a project devoted to provision of mouse monoclonal antibodies for diagnosis of chronic alcoholism and re-shaping of monoclonals through protein engineering to provide treatment regimes for alcoholism. The post is for one year and will be held in the Department of Genetics and Microbiology, which has a major reshaping group in protein-engineering of immunoglobulins.

For further information on the project contact Professor W J Harris on (0224) 272392. Further particulars and application forms from the **Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX,** (tel 0224 273500) to whom applications (2 copies) should be returned by 6 October 1989 quoting reference number LW/051. (1569)A

THE INSTITUTE FOR ADVANCED STUDY

Will have an opening for a long-term (5 year) member in high energy physics and field theory beginning September 1990. Salary is above post-doctoral level and is commensurate with qualifications. In addition to exceptional qualifications for pursuing his or her individual research, the successful candidate should be interested in talking to, and possibly collaborating with, other post-doctoral members. The duties of a long-term member consist only of performance of individual research, being helpful to other members in their research, helping run seminars and reviewing post-doctoral applications. Requests for application should be addressed to **Michelle Sage, School Administrative Officer, School of Natural Sciences, Institute for Advanced Study, Princeton, NJ 08540.** The closing date for applications is December 15, 1989. The Institute for Advanced Study is an affirmative action/equal opportunity employer. (NW4209)A

QUEEN MARY & WESTFIELD COLLEGE

University of London

Post Doctoral Research Assistant — Stream Ecology

The Natural Environment Research Council have awarded a grant to Dr Hildrew in the School of Biological Sciences to work on "Disturbance and Refugia. Flow and the Ecology of Stream Animals" Applications are invited from suitably qualified candidates, experience in stream hydraulics, population ecology and/or modelling would be an advantage A current driving licence is essential

Salary will be to £13,386 inclusive of London Allowance Interested candidates should send a CV with the names of two referees to **Dr A G Hildrew, School of Biological Sciences, Queen Mary & Westfield College, Mile End Rd, London E1 4NS** from whom further details are available. Closing date is 30th September 1989 (1544)A

DEPARTMENT OF ECOLOGY & EVOLUTIONARY BIOLOGY

UNIVERSITY OF ARIZONA

BEHAVIOR:

Applications are invited for a tenure-track position in the area of behavior, including its evolutionary aspects. Applicants pursuing field or experimental studies are of particular interest. High originality in research and talent as a teacher will be important criteria used in selecting among applicants. This appointment will probably be made at the assistant professor rank. Applicants should mail a curriculum vitae, statement of research plans, reprints or preprints, and arrange to have at least three letters of reference sent to **Conrad A. Istock, Department of Ecology and Evolutionary Biology, University of Arizona, Tucson, AZ. 85721.** The period for applications closes December 15, 1989. *The University of Arizona is an equal opportunity/affirmative action employer.* (NW4230)A

IARMACOLOGIST, ASSISTANT/ ASSOCIATE PROFESSOR

full time, tenure track posi-)n is available for a basic ientist with an earned doc-rate in pharmacology to velop and direct a pharma-)logy course for sophomore edical students. Develop-ent of a research program is :pected. One-two years post-)ctoral experience is desir-)le. Applicants should send irriculum vitae and names/ ldresses/phone numbers of ree references to: **B.H. igatz, Ph.D., Chair, Search)mmittee, Fort Wayne enter for Medical Education, diana University School of edicine, 2101 Coliseum Blvd. , Fort Wayne, IN 46805.** diana University is an equal)portunity/affirmative action lucator, employer, and con-actor, M/F (NW4226)A

AFRC INSTITUTE OF ANIMAL PHYSIOLOGY AND GENETICS RESEARCH
BABRAHAM, CAMBRIDGE, CB2 4AT.
OLECULAR BIOLOGIST

post-doctoral molecular bio-st is required to fill a three year C-funded vacancy in the)artment of Cell Biology. The ject concerns the function and ilation of the mucosal immune em and, in particular, inter-)ns between lymphocytes and gut epithelium. The immediate ective will be to study, at the e level, the structure and regu-)n of a newly discovered inte- that is expressed on mucosal phocytes. Applicants who are erienced in gene cloning, iencing and expression ems and also have some rest in immunology, will be at dvantage.

he appointment will be made ie upper region of the Higher ntific Officer scale (starting ry up to £13,235) with a non-:ributory superannuation :me. 25 days leave

pplications, including CV and ies of two referees, to the Per-iel Officer, quoting Ref. PJK/ C, by 30 September 1989. For ier details contact Dr. P J. haw (Cambridge (0223) 312 ext. 405). (1579)A

nature

– the professionals' choice

UNIVERSITY OF HONG KONG
POSTDOCTORAL POSITION IN PATCH-CLAMP STUDIES
Department of Physiology

Applications are invited, from those with experience of patch-clamp technique, for a WHO supported project on the role of ion channels in fluid secretion by the epididymis. The appointee will join a team in the Department where patch clamp facilities are available.

Appointment will commence as soon as possible and is for two years. Annual salary is about US$22,000, with medical benefits provided A return airfare will also be provided if required. At current rates, income tax will not exceed 15% of gross income.

Send curriculum vitae, statement of research interests, and the names of three referees to Dr P.Y.D. Wong, Department of Physiology, Faculty of Medicine, University of Hong Kong, Sassoon Road, Hong Kong as soon as possible and not later than October 20, 1989. Tel: (852) 5-8199202, Telex: 71919 CEREB HX, Fax: (852) 5-8559730. (W6480)A

GRANTS & SCHOLARSHIPS

THE ROYAL SOCIETY

Travel and Subsistence Grants from the Parliamentary Grant-in-Aid.

Notice is hereby given that the following closing dates will apply in respect of applications for travel and subsistence grants: 1 October 1989, 1 December 1989, 1 March 1990, 1 June 1990. Grants are usually awarded only in respect of short scientific visits overseas of up to 13 days (generally for Conference attendance), although certain longer term visits to the USA may also be considered. Applications should be submitted on forms to be obtained from the **Executive Secretary, (Ref. BdeV), The Royal Society, 6 Carlton House Terrace, London, SW1Y 5AG.** (01-839 5561, ext 222). Grants are only available to scientists of at least Ph.D. status who are ordinarily resident in the UK and are not employed by the research Councils, government bodies, the National Health Service, state-aided research establishments, industrial or commercial bodies.

For certain major conferences there may be special closing dates and persons requesting forms should indicate the meeting they wish to attend.

Applications in respect of longer term visits overseas can be considered under other schemes administered by the Society and those wishing to apply should enquire well in advance of travel indicating the approximate duration of the visit, and the country to be visited. (1582)H

STUDENTSHIPS

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)
Department of Biochemistry and Chemistry
SMITH, KLINE AND BEECHAMS PLC, WELWYN, Herts.
SERC–CASE Studentship

Applications are invited for a studentship to Dr S J. Perkins, Dr K.R. Bruckdorfer (RFHSM), Dr K.E. Suckling and Dr P.H.E. Groot (SKB) to study the properties of oxidatively-modified plasma lipoproteins, their role in atherosclerosis, and the influence of anti-antherosclerotic drugs.

Applicants should have a First or Upper Second Honours degree in Biochemistry or other relevant subject. The stipend is £4,690 p a., supplemented by SKB (under review), and there are prospects of visits to French laboratories. Applications, including a curriculum vitae and the names and addresses of two academic referees, should be sent to **Dr K.R. Bruckdorfer, Department of Biochemistry and Chemistry, R.F.H.S.M., Rowland Hill Street, London NW3 2PF,** from whom further details can be obtained on 01-794-0500 Ext: 4218. (1549)F

BIRKBECK COLLEGE
(University of London)
CORDA PHD STUDENTSHIP

The above studentship funded by CORDA (the Heart Charity) is now available for a period of up to 3 years. Applicants should hold a good honours degree in chemistry, biochemistry or a related subject.

For more details and an application form contact the **Assistant Secretary (Personnel), Birkbeck College, Malet Street, London WC1E 7HX.** Telephone: 01-631 6529. The closing date is *29 September 1989.* (1571)F

UNIVERSITY OF BATH
S.E.R.C./C.A.S.E. Ph.D. STUDENTSHIP IN PHARMACOLOGY

Applications are invited for a Ph.D. Studentship to work on the role of neutrophils in mediating ischaemia/reperfusion induced cardiovascular damage. This project which is funded for three years is in collaboration with Dr. J.F. Waterfall at Roche Products. Applicants with a suitable First or Upper Second Class Honours Degree should send their C.V. and the names of three referees to **Dr. B. Woodward, Pharmacology Group, University of Bath, Bath, Avon, BA2 7AY.** Closing date 1st October 1989. (1556)F

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)

Persons of British or Irish nationality are invited to apply for an Anatomical Society Studentship, leading to Ph.D. A graduate or Master in anatomy, bioengineering, ergonomics, kinesiology, medicine, para-medicine, human physiology or sports science is sought for early appointment.

Area of study: The human musculo-skeletal system in assymetric working postures, its deployment during manual exertion and the development of predictive computerised biomechanical models Co-researchers are involved in ergonomics, health and safety, strength and posture.

For details of project, laboratory and terms of reference, contact **Professor D.W. Grieve, Biomechanics Laboratory, R.F.H.S.M., Rowland Hill Street, London NW3 2PF. Tel: 01-794 0500 Ext: 4351.** (1543)F

The Karnofsky Fellowship in Cancer Research Honours

Dr David A Karnofsky, former chief of Medical Oncology at Memorial Hospital, New York, and head of the Division of Chemotherapy Research, Sloan-Kettering Institute, whose research established world-wide recognition of the importance of chemotherapy in the treatment of cancer.

Dr Karnofsky was a member of the St. Jude Children's Research Hospital Scientific Advisory Board and this fellowship, offered each year, is in his memory The fellowship is available to investigators with either a Ph D or M.D. degree who are beyond the junior level of accomplishment and who would like to gain further experience and expertise in one of the biomedical research specialties available at St. Jude

These include biochemistry, immunology, tumor cell biology, pharmacology, pharmacodynamics, virology and molecular biology, pediatric oncology, hematologic malignancies and infectious diseases. Awards are made for up to two years Stipends are highly competitive

Application deadline 1 January 1990
Award notification 15 February 1990
Beginning date 1 July 1990
Send inquiries to

Allan Granoff, Ph.D., Deputy Director
St. Jude Children's Research Hospital
P.O. Box 318

Equal Employment/Affirmative Action Employer (NW4232)E

The Journey Fellowship in Biomedical Research

is offered annually by St. Jude Children's Research Hospital. It honors the memory of Dr Leon Journey, a distinguished cell biologist and electron microscopist who served on the institution's staff for 10 years The fellowship is open to a junior investigator with an M D or Ph.D. degree who seeks training experience in one of the specialty areas of biomedical research available at this center. These include biochemistry, immunology, tumor cell biology, pharmacology, pharmacodynamics, virology and molecular biology, pediatric oncology, hematologic malignancies and infectious diseases.

Journey fellowships are made for up to two years and are based on merit, recommendations and promise of a productive career in biomedical research Stipends are highly competitive.

Application deadline 1 January 1990
Award notification 15 February 1990
Beginning date 1 July 1990
Send inquiries to:

Allan Granoff, Ph.D.,
Deputy Director

The Lamont-Doherty Geological Observatory of Columbia University

POSTDOCTORAL FELLOWSHIPS in the EARTH AND OCEAN SCIENCES

The Lamont-Doherty Geological Observatory of Columbia University invites recent Ph.D. recipients or candidates for their degrees in 1988 in any field of the Earth and Ocean Sciences to apply for Postdoctoral Fellowships awarded for a period of one year (extendable to two years, in special instances) beginning in September 1990 with an annual stipend of $30,500.

The deadline for completed applications is January 15, 1990. Application forms may be obtained by writing to the **Office of the Director, Lamont-Doherty Geological Observatory, Palisades, New York 10964.** Award announcements will be made on or about February 28, 1990.

Columbia University is an Affirmative Action/Equal Opportunity Employer. (NW4211)E

INSTITUTE OF CHILD HEALTH
University of London

POSTDOCTORAL FELLOWSHIP

INSTITUTE OF CHILD HEALTH
(University of London)

Applications are invited for a postdoctoral biochemist funded by Action Research for the Crippled Child for 3 years. The project is to study fatty acid oxidation in children with inherited metabolic disorders using stable isotope techniques. Experience of mass spectrometry would be an advantage. Salary will be at an appropriate point on Research IA scale, £12738-14529 inclusive of London Weighting.

Applications which should include a Curriculum Vitae and the names of two referees should be made to either **Dr J V Leonard** or **Dr D P R Muller, Department of Child Health, Institute of Child Health, 30 Guilford Street London WC1N 1EH** (Telephone 01-242 9789), who will also be pleased to provide further information. ST. MARY'S HOSPITAL MEDICAL SCHOOL
(a constituent College of Imperial College of Science, Technology and Medicine)
(University of London)
Nofolk Place, LONDON W2 1PG

DEPARTMENT OF PHARMACOLOGY & TOXICOLOGY

Post-doctoral Research Fellowship in Dermal Toxicology

Applications are invited for a Post-doctoral Research Fellowship to work on a Health and Safety Executive-funded project to investigate the absorption and metabolism of environmental and occupational chemicals, including pesticides and aromatic amines, in rat and human skin The work, which will be carried out under the direction of Professor J. Caldwell and Dr. S A. Hotchkiss, will involve the use of a wide range of techniques, including in vitro and in vivo models for dermal absorption and metabolism, skin cell culture and culture of whole skin explants Analytical methodologies will include HPLC, radio-HPLC and GLC. Applicants should hold, or be about to obtain, a PhD in a relevant scientific discipline and a background in mammalian cell culture techniques would be desirable

The position is available for 3 years, commencing October 1989. Starting salary will be in the range £10,458-£16,665 pa + £1650 pa London Allowance. For further information about the project, contact Dr. S.A Hotchiss, Department of Pharmacology & Toxicology at above address, or telephone (01) 723-1252 Ext 5880.

Interested applicants should apply in writing with full C V and names and addresses of 2 referees to **Personnel Department** at above address. Please quote Ref. PRF/JC. (1564)E

The Wellcome Trust

Long-term and Short-term Wellcome Travelling Research Fellowships to Europe 1990-91

Applications are invited from post-doctoral research workers who have been engaged in research in the United Kingdom or the Republic of Ireland for the past three years for the award of Wellcome-European Research Fellowships to start in 1990/91. Pre-doctoral candidates may apply, but may not take up an award until their doctorate is awarded. These awards include the Trustees' special fellowships to Czechoslovakia, Denmark, Finland, Hungary, Norway and Sweden.

The object of these fellowships is to encourage working visits to countries in Western and Eastern Europe by investigators in any branch of the natural and clinical sciences which has a bearing upon human or animal medicine (except cancer)

Candidates must make their own arrangements with the department in which they propose to work, and written evidence must be submitted confirming these arrangements.

Long-term fellowships are normally held for one year, but may be extended to two following a satisfactory review.

Short-term fellowships are available to allow more senior scientists to make short working visits of three-six months. Applications are accepted at any time.

Stipends, according to age and experience, are within the range of £10,458 to £17,994 per annum. A special cost of living allowance applicable to the country in which the candidate wishes to work is given where necessary. Travelling and some incidental expenses are also provided.

Requests for application forms should include a brief **curriculum vitae** and an outline of the proposed research and should be addressed to:

The Grants Section (Europe)
The Wellcome Trust
1 Park Square West
London NW1 4LJ

Applications for long-term fellowships are considered in competition twice yearly. Completed forms must be returned by **24th November 1989 and 1st May 1990.**

Fellowships are also available to encourage Eastern and Western European scientists to work in the UK Intending applicants should either contact the Wellcome Trust or contact the appropriate organisation with which the Trust has established special fellowship schemes in the following countries: **Czechoslovakia,** Postgraduate Medical and Pharmaceutical Institute; **Denmark,** The Carlsberg Foundation; **Finland,** The Sigrid Jusélius Foundation; **Hungary,** The International Cultural Institute; **Norway,** The Anders Jahre Foundation; **Sweden,** The Swedish Medical Research Council.

STA FELLOWSHIPS

Postdoctoral Fellowships in Japanese Government Laboratories

The Japanese Science and Technology Agency (STA) is offering postdoctoral fellowships to scientists and engineers of the countries listed below for periods of 6 months to 2 years to be held in any Japanese national laboratory (excluding university and university-affiliated laboratories). Over one hundred Japanese research laboratories covering almost all areas of science, engineering and medicine are participating in the scheme.

The fellowships are open to young PhD holders of under 35 (although older researchers will be considered) from universities, research councils, government research laboratories and industry. Any science or engineering discipline will be considered except military R & D. Applicants will be required to supply a letter of invitation from their Japanese host institution (the organizations listed in Table 1 provide help in contacting suitable host institutions).
Those in the final stages of a PhD may also apply.

There are no closing dates but candidates are encouraged to submit their applications as soon as possible. Fellowships for fiscal 1989 must be taken up by March 1990.

FELLOWSHIP AWARDS

Fellowships include round-trip air tickets (economy class) and the following tax-free allowances:

1) Living allowance: ¥270,000 (about US$2,000) a month
2) Family allowance: ¥ 50,000 a month
3) Housing allowance: up to ¥100,000 a month
   Apartments will normally be provided to awardees. The apartment floor area is 40 m^2 for awardees unaccompanied by their family and 60 m^2 for awardees to stay with their family in other than metropolitan areas such as Tokyo. If an awardee prefers to use a larger apartment because of the family size or otherwise ¥100,000 maximum per month may be paid as housing allowance; any shortfall is to be borne by the awardee.
4) International relocation allowance: ¥200,000
5) Travel allowance: ¥100,000 a year
   (within Japan)
6) Japanese language lesson courses are to be provided free of charge to the STA Fellowship awardees and their family members in Tsukuba area. Those who live in places other than the Tsukuba area will be entitled to reimbursement of Japanese language school tuition up to a specified amount.
7) Excursions or the like will be held to help make the Fellowship awardees and their family members in Tokyo/Tsukuba areas familiarized with Japan's culture, tradition and history.

In addition, ¥1,480,000 per year will be paid to the host institute to cover research costs and insurance for researchers will be paid by JISTEC during their stay in Japan to cover medical care.

APPLICATION PROCEDURE FOR STA FELLOWSHIP

Management of the STA Fellowship, including recruitment of candidates, is entrusted to the Japan International Science and Technology Exchange Center (JISTEC).

Responsible organizations overseas which represent the governments of their respective countries are given in Table 1.

A researcher wishing to be awarded the STA Fellowship should apply to the responsible organization in his/her country. Candidates are required to contact the desired host institute and obtain a letter of acceptance before filling an application with their government. Further information regarding the STA Fellowship and host Institutes is available from the responsible organizations.

A researcher whose country is not listed in Table 1 could contact a Japanese host institute directly, which in turn may recommend the reseacher to JISTEC as a candidate for STA Fellowship.

Fig. 1 shows the process from consult/contact to receipt of award.

King's College London

COLLEGE POST DOCTORAL RESEARCH FELLOWSHIP

A position is available for a research worker in the field of spectroscopy, especially EPR, as applied to metalloproteins. It has been established by Kings College with the specific aim of coordinating the activities of a number of research groups.

The Life Science Faculty of Kings College at Kensington has been recently reorganized and is well equipped with facilities for crystallography and spectroscopy, with supporting facilities in genetics, immunology, and biotechnology. Other college facilities and those nearby in the University of London include state-of-the-art multiple-frequency continuous-wave and pulsed EPR spectroscopy and ENDOR.

Studies in the area of metalloproteins cover a wide range, with particular emphasis on iron. This includes the biochemical action of haem and non-haem iron proteins, iron in clinical medicine, and free-radical damage. Possible areas of investigation include the environment of metal centres in biological systems and the development of new spectroscopic approaches.

The appointment is for two years in the first instance, starting salary up to £14,031 inclusive.

Applications, including CV and the name of two referees, should be sent, before October 30th to: **Dr. R. Cammack or Dr. J.M. Wrigglesworth, Department of Biochemistry, Kings College, Campden Hill Rd, London W8 7AH.** Tel: 01-937 5411, from whom further details may be obtained.

(1542)E

UNIVERSITY OF UMEA

Inst. Cell Mol Biol

POSTDOCTORAL FELLOWSHIP

Applications are invited for a post-doctoral fellowship to study transthyretin and its role in amyloidosis. Biochemical characterization of genetic variants produced by recombinant techniques will be done. The successful candidate should have a background in protein chemistry, show a strong commitment to scientific research and work closely together with molecular geneticists. The institute is well equipped and provides an excellent scientific atmosphere.

More information from **Prof. Erik Lundgren, Inst Cell Mol Biol, Univ. Umea, S-901 87 Umea, Sweden. Tel. 46-90-13 36 36.** Applications with CV and the names of two referees should be sent to the above address before 28 Sept 1989. Reference No. 11. (W6491)E

Symposium on

Childhood Leukemia:

— Present Problems and Future Prospects —

sponsored by

The Children's Cancer Association of Japan

(Chairman: Keiji Iwata)

December 7–9, 1989, Tokyo

Topics: Leukemia cell and molecular biology
Epidemiology
Treatment of childhood leukemia
Patient supporting system.

Invited speakers: M.F. Greaves (Univ. of London), M. Ogawa (Univ. of South Carolina), J.C. Reed (Univ. of Pennsylvania), M.L. Cleary (Stanford Univ.), J.M. Birch (Univ. of Manchester), J.V. Simone (St. Jude Hospital), H. Riehm (Hannover Medical School), W.A. Bleyer (Univ. of Washington), R.P. Gale (UCLA), G.P. Monaco (Candlelighters Childhood Cancer Assoc.), J. Pritchard (Hospitals for Sick Children, London), A.E. Evans (Children's Hospital of Philadelphia), I.M. Martinson (Univ. of San Francisco).

Language: English.

Chairman of the Organizing Committee: Noboru Kobayashi, M.D.

AWARDS

POTAMKIN PRIZE FOR ALZHEIMER'S DISEASE RESEARCH

A prize of £100,000 will be awarded by the American Academy of Neurology to a person in recognition of major contributions to the understanding of the causes and the prevention, treatment, and ultimately the cure for Alzheimer's disease and related disorders.

Candidates may be nominated on a world-wide basis from any of the biological disciplines including biochemistry, molecular biology, molecular genetics, pharmacology, immunology, physiology, cell biology or neuropathology.

A nomination application, nominating letter citing the scientific accomplishments of the candidate in detail, two supporting nominating letters, a curriculum vitae, and up to six (6) selected reprints in nine (9) complete sets are required.

The deadline for receipt of materials is November 1, 1989. No nomination will be considered unless it is complete. The awardee must be present at the AAN annual meeting in Miami Beach, Florida, U.S.A., on Wednesday, May 2, 1990.

Request application and submit nomination to:

Potamkin Prize for Alzheimer's Disease Research Award Committee
American Academy of Neurology
2221 University Avenue S.E. – Suite 335
Minneapolis, MN 55414 (612) 623-8115

The Potamkin Prize is funded through the philanthropy of the Potamkin Foundation. (NW4056)N

ANNOUNCEMENTS

South African Scientists Abroad

South African science and engineering graduates, who are currently working or extending their studies abroad, are invited to register with the Foundation for Research Development (FRD).

All those listed on the FRD Register of South African Scientists Abroad (SASA) will be kept up to date on science and technology issues in South Africa and can obtain further information from FRD. Should a member wish to return to South Africa, FRD could provide contacts with potential local employers.

For an application form, write to:

Are you a science detective?

Do you spend hours searching the library shelves for clues to the whereabouts of this week's issue of Nature or waste time tracking down the last person on the circulation list?

Whether it's the latest developments in AIDS vaccines, maps of the sea bottom, debates on Darwinism or details on supernovae explosions that you're looking for, you need search no longer.

A personal subscription to Nature puts the most recent scientific developments in your hands only hours after the text goes to the printers.

Not only that, but you can read Nature at your leisure without fear of being chased by librarians or colleagues frantic for that one treasured copy.

You can even build up a permanent Nature reference library with its own Nature Index to make the information instantly accessible and ready to hand.

Stop the search now

Take out a personal subscription to Nature today at HALF PRICE.

When The Pressure's On.

Introducing PosiBlot™ Pressure Blotter.*

Decrease Transfer Time 3 fold / Increase Transfer Efficiency.

The PosiBlot™ pressure blotter replaces vacuum blotting or electrotransfer for Southern and Northern nucleic acid transfer. The amount of negative pressure applied during vacuum blotting (30 mm Hg below atmospheric) is limited by gel collapse. Since pressure blotting does not dehydrate the gel, collapse is not a problem even at positive pressures of 100 mm Hg above atmospheric. Since the rate of nucleic acid transfer is linearly proportional to the pressure differential, pressure blotting greatly increases the speed and efficiency of blotting.

*Patent Pending

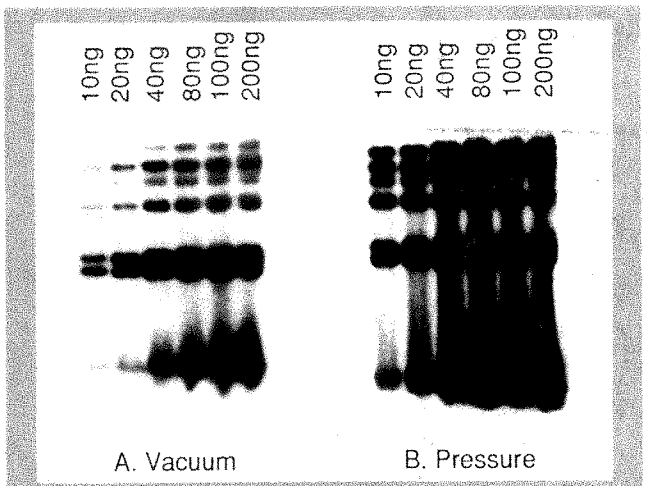

Figure legend: ^{32}P end-labeled lambda Hind III markers were electrophoresed in 0.8% agarose. The DNA was then transferred to a nylon membrane with a vacuum blotter at 30 mm Hg below atmospheric or with the PosiBlot™ pressure blotter at 100 mm Hg above atmospheric. Both transfers were carried out for 15 minutes. As can be seen, pressure blotting transferred significantly more DNA in the same period of time, especially in the higher molecular weight range (largest band is 23 kilobases).

The Applied Biosystems PCR-MATE works hand in glove with GeneAmp™ PCR.*

PCR-MATE is cost-effective. The instrument has a low price tag, a low cycle cost, and a fast cycle time. Reagent usage is kept to a minimum. The instrument supports various scales of synthesis for the economical production of DNA, including primer length DNA. All of this works to make the PCR-MATE an easily affordable addition to the laboratory.

PCR-MATE produces high-quality DNA that saves you time throughout your experiment. After synthesis, only minimal preparation is needed before its use. And the DNA is guaranteed to be 99.8% authentic when compared to biologically derived sequences. This means you get complete amplification of the target sequence. You'll get results you can count on!

PCR-MATE is compact and easy to use. Its benchtop design takes up little space in the lab, and the instrument goes to work at the touch of a button. For more information, call your nearest office. We'll work hand in glove with you to meet your synthetic DNA requirements.

*GeneAmp is a trademark of Perkin Elmer Cetus. The GeneAmp Polymerase Chain Reaction (PCR) Process is covered by Perkin Elmer Cetus' U.S. Patent No. 4,683,202. No license to use the PCR Process is given or implied by Perkin Elmer Cetus' licensing of PCR-MATE.

Autumn collection

Do your labs need an equipment update for the winter load? Some new lines and innovative products are now at hand.

BLOOD ANALYSIS

AN increasing number of reports have identified the presence of functionally abnormal variants of fibrinogen in patients with liver disease. The plasma from these patients may yield a thrombin time that ranges from normal to modestly prolonged; however the Reptilase time has become a particularly useful and sensitive procedure for monitoring patients with hepatic disorders or undergoing liver transplants. The new Reptilase-PC kit from Bio/Data is designed for the performance and control of Reptilase time. It contains 1.0 ml of purified venom from the *Bothrops atrox* pit viper and 1.0 ml of lyophilized normal control plasma specifically designed to assure quality control of the Reptilase time. Available from **LEP Scientific** Reptilase-PC is compatible with all coagulation instruments or manual techniques. *Reader Service No. 599.*

THE popular Platelet Aggregation Profiler from Bio/Data has been upgraded. Marketed in the UK by **LEP Scientific,** the new model PAP-4C includes a chromogenic test mode for all commercially available chromogenic test kits such as anti-thrombin III, protein C and plasminogen. The PAP-4C

PAP-4C Platelet Aggregation Profiler also performs chromogenic assays.

provides four test modes which enable the laboratory to perform platelet aggregation, Von Willebrand assays, leukocyte aggregation and chromogenic assays in a single instrument. All four modes require only micro volumes of reagent and provide sufficient automation in each test mode to reduce the operator's manual intervention. In chromogenic assay mode, the PAP-4C prompts the operator through each step of the procedure. Curve generation and interpolation of test results are automatic with curve storage for four separate assays at one time. The PAP-4C measures the initial rate reactions rather than the endpoint for more rapid and accurate results. *Reader Service No. 598.*

THE compact **Coulter** T8-AS haematology analyser features a fully automated sampling system designed to provide reproducible, fast and accurate results for eight parameters. Capable of a throughput of 75 samples per hour, the autosampler continuously assesses the total system as the samples are run through. This gives the Coulter T8-AS total walkaway capability. If at any stage the operator is required, an audible alarm is set off. The T8-AS is able to accommodate any vial size, run urgent Stat samples and provide a choice of sample identification. Safety of operation is ensured by the use of a closed vial aspirator, which punctures through the cap of sample tube. Automatic backwash eliminates sample carryover whilst automatic aperture cleaning maintains an optimal counting environment. *Reader Service No. 597.*

Classic symposium

A MULTIDISIPLINARY scientific symposium and exhibition is to be held at the National Motorcycle Museum in Solihull, on 26 and 27 September. **Coulter** Classics is similar in format to the company's successful symposium held in Stratford last year. This event will once again bring together a panel of guest speakers. Three simultaneous lecture programmes will be run: haematology; particle technology; and flow cytometry/immunology. There will also be ample time to view the 'classic' exhibits. *Reader Service No. 596.*

Olympus have a mic of your scient

Like the life forms in the Petri dishes above, the Olympus range of microscopes has grown and grown.

So much so, that we've now a more comprehensive choice of high quality microscopes than any other microscope company.

(With 48 models in our range, we've double the number of our nearest competitor.)

Which means, in fact, that whatever your specific requirements, we've a suitable microscope for you.

At school, college or university, for example, you need practical, ruggedly-built student laborato microscopes.

Like the Olympus CH-2 Series.

And for the most sophisticated research wo you'll certainly need the most sophisticated resear microscope. Namely, the advanced design of our Vane

cope for every stage
development.

Staphylococcus Epidermidis
grown on horse blood agar.

hotomicroscope, with its automatic focusing and
vo built-in cameras.

In all, no other range of microscopes focus quite
s clearly on your individual scientific needs as the
)lympus range.

So find out more by filling in our coupon.

You never know what you might find taking shape
1 your Petri dish.

To: Olympus Optical Co. (UK) Limited, 2-8 Honduras Street, London EC1Y 0TX. Telephone: 01-250 0179. Please send me further information on your range of Biological Microscopes ☐ Materials Microscopes ☐ Image Analysis Equipment ☐ Photo Micrographic Attachments ☐

The Compact-10 Plus blood group analyser marketed by LEP Scientific.

THE Compact-10 Plus™, marketed by **LEP Scientific,** is a 'benchtop' size blood group analyser. It is calculated to use only 0.4 pence in reagents per sample and is capable of processing 100 samples per hour. The scientific team responsible for its development had, as their main objective, the production of an instrument with the same size and operating costs as a 'microtitre' system, with the benefits of full automation and performance of large 'top of the range' analysers. Its performance in terms of 'reject frequency' is comparable to the best available (about 3% on patient samples). It has numerous features such as 'intelligent sampling' which would normally only be available on analysers costing four to five times more. *Reader Service No. 595.*

A DEVELOPMENT from **Dynatech Laboratories,** which extends the use of its MR5000 ELISA Microplate Reader, is now available for labs involved with agglutination inhibition testing and other blood grouping techniques. By plugging in a Dynatech-designed Agglutination module, the standard MR5000 can be instantly converted from an ELISA reader to a reader for routine, large-scale agglutination tests, in addition to existing ELISA capabilities. Test results are printed out on an 80 column NLQ printer, supplied as standard with the system, in a form which is immediately useful at blood transfusion centres, hospital blood banks and medical research centres. A threshold can be set, against a cutoff control well, enabling results to be expressed as positive or negative, on a convenient 8 × 12 printout. A bi-directional RS232 port allows the MR5000 to operate under computer control when used with advance blood grouping software from Sanguin. *Reader Service No. 594.*

MR5000 automatic microplate reader from Dynatech Laboratories.

USING Stat Cytometry, a complete patient immunological profile, from whole blood printed results, can be produced in 30 minutes, says manufacturer **Coulter.** The complete analysis package comprises instruments, reagents, controls and calibrators to ensure the quality, reliability and reproducibility of results. Preparation and analysis are designed to be simple. The blood sample is divided into the required number of test tubes, and the appropriate Cytostat monoclonal antibodies are added. This is followed by a 10-min incubation at room temperature. Using Immunoprep reagents, the Coulter Q-Prep immunological workstation converts the whole blood to fixed sample in 35 seconds. This is then ready to run on the new Coulter Epics Profile II flow cytometer. Once all the samples have been analysed the complete patient printout is available. Further analysis of the data is possible using the Gateway List Mode data analysis software. *Reader Service No. 593.*

ANTIBODIES

A COMMERCIALLY available monoclonal antibody to the mouse F4/80 antigen has been announced by **Serotec.** Mouse Mononuclear phagocytes possess a 160-K plasma membrane component that is recognized by his new antibody. The F4/80 antigen is a maturation marker for macrophages in bone marrow culture, but is absent on macrophages in other blood cell types and in lymphoid and haemopoitic organs. *Reader Service No. 592.*

A RECENT addition to **Serotec's** growing product range is a monoclonal antibody to BUdr. This antibody reacts with single-stranded DNA (denatured) which has BUdr attached. It gives strong staining down to concentrations of approximately 6-10 $\mu g\,ml^{-1}$, and its sensitivity is down to 0.5 pg. Available in a 0.2-mg vial of purified lyophilized ascites directly from Serotec. *Reader Service No. 591.*

ALSO available from **Serotec** are anti-hapten antibodies. These new antisera were raised in rabbits (except monoclonal anti-fluorescein) against covalent

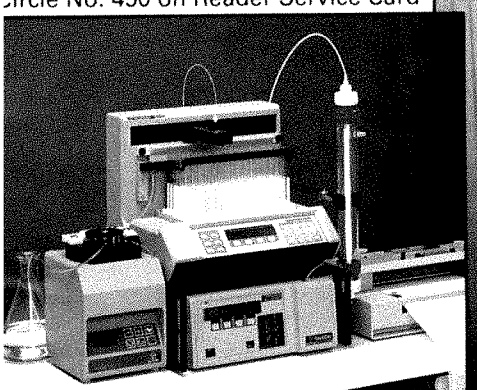
Counting on flow

THE Sysmex R-1000 Reticulocyte Counter from **LEP Scientific** uses the principle of flow cytometry to achieve improved accuracy for reticulocyte analysis and automation. Fully automated analysis performed by the R-1000 overcomes many of the problems encountered with conventional reticulocyte counting techniques. In the R-1000 the blood cells are first stained with a fast acting fluorescent dye and then passed through a Sheath Flow Cell, through which a laser beam is shone. Using an argon laser as a light source, the R-1000 uses forward light scatter to determine relative cell size and density, and side fluorescence detection to establish RNA content. By combining these two parameters, reticulocyte count and reticulocyte ratio are determined with accuracy. A 2-D scattergram is produced using the forward light scatter intensity versus the fluorescence intensity parameters, to separate reticulocytes from mature red blood cells and platelets. *Reader Service No. 590.*

ILSON INTRODUCES THE MINIPULS 3

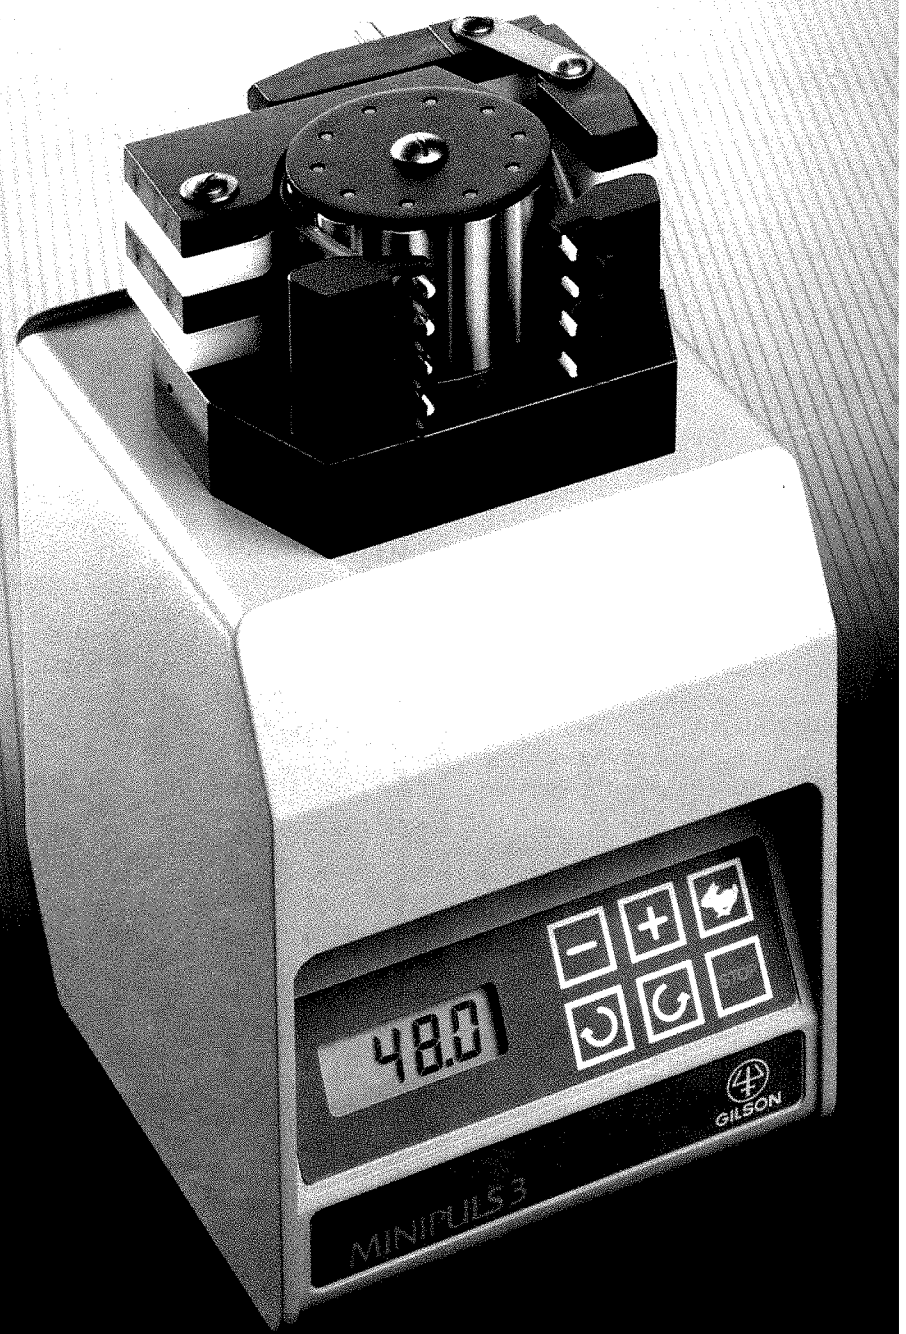
A high performance peristaltic pump.

/ide flow range
ach application puts unique demands n a peristaltic pump. That's why Gilson ffers the Minipuls 3 with a wide variety of ump heads to meet different flow rate nd throughput requirements. Choose a 2, 4 or 8 channel head for flow rates om 1 µL/min to 220 mL/min.



'ulse-free flow
lany analytical techniques demand an dvanced solvent delivery system. hanks to a high performance drive sys-em, the Minipuls 3 can operate at maxi-ıum pressures with an ultra-smooth ow.

)utstanding reliability
he Minipuls 3 will function reliably even ı the most demanding industrial envi-onments. Speed remains stable inde-ıendently of normal temperature var-ations between 0 and 40 °C and against ıack pressures up to 5 bars (72 psi).



Reproducibility
Precise reproduction of flow rates lepends on reproducible drive speed. he Minipuls 3 is microprocessor con-rolled. No matter how many times you eset your pump, you can always come ıack to a previously selected value.

Remote control
The Minipuls 3 is capable of bidirectional ommunications with computers, Gilson raction collectors, Gilson autosamplers, ınd other instruments.

For more information, please contact your nearest Gilson representative, or write to us.
Circle No. 450 on Reader Service Card

Recommended for low pressure liquid chromatography.

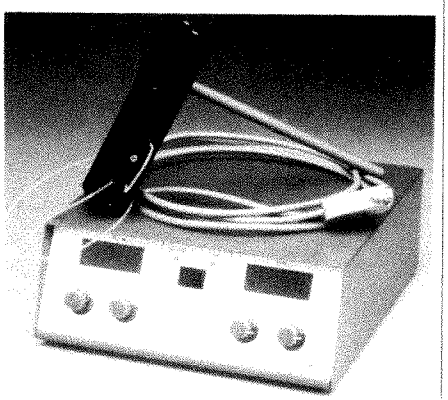
conjugates of the haptenic groups (biotin, fluorescein etc.) and keyhole limpet haemocyanin. Biotin and fluorescein in particular are used to label proteins and nucleic acids covalently for detection in a variety of situations, for example, Western blotting and immunocytochemistry. Labelling of proteins with other haptens — pyrene and TNP — both of which are commercially available with easy-to-conjugate reactive groups from a number of sources, can also be used in the same way, thus adding flexibility to experimental protocols. The existence of completely independent labelling systems allows two or more labelled proteins to be detected simultaneously. In addition, both TNP and pyrene are fluorescent. The reagents are supplied as rabbit antisera on tissue culture supernatant. *Reader Service No. 589.*

ANTI-BIOTIN and anti-avidin D antibodies in labelled and unconjugated form are now available and listed in **Vector Laboratories'** new 1989 catalogue. Produced by hyperimmunizing goats with biotin and avidin D, the new products are first affinity purified and then labelled with alkaline phosphatase or horseradish peroxidase. These conjugates are prepared from the highest specific activity enzymes and are optimally coupled for stability and activity. Labelled anti-biotin products find particular use with biotinylated nucleic acids or in systems where the high biotin/avidin affinity is less desirable. Labelled anti-avidin D product applications include tissue staining and avidin localizatin. Additional products in this area are available from Vector Laboratories. *Reader Service No. 588.*

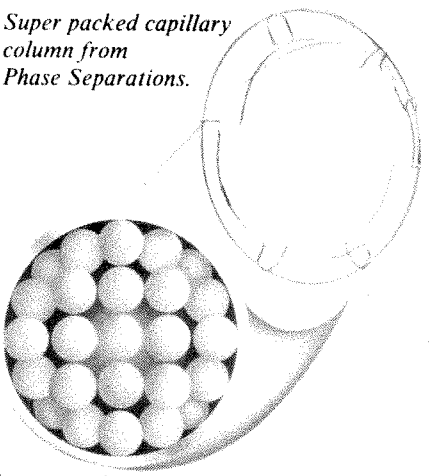


Demo disk

SPECIALIST supplier of chromatography data systems, **Axxiom Chromatography,** has produced a demonstrator disk for its range of PC-based chromatography data systems. The demonstration disk, which is available free, will run on any IBM PC, AT, XT or compatible computer. The disk has been produced using the latest form of interactive presentation utilities. It runs at a user-controlled speed and takes the user through all the key features and operating modes of Axxiom data systems. *Reader Service No. 587.*

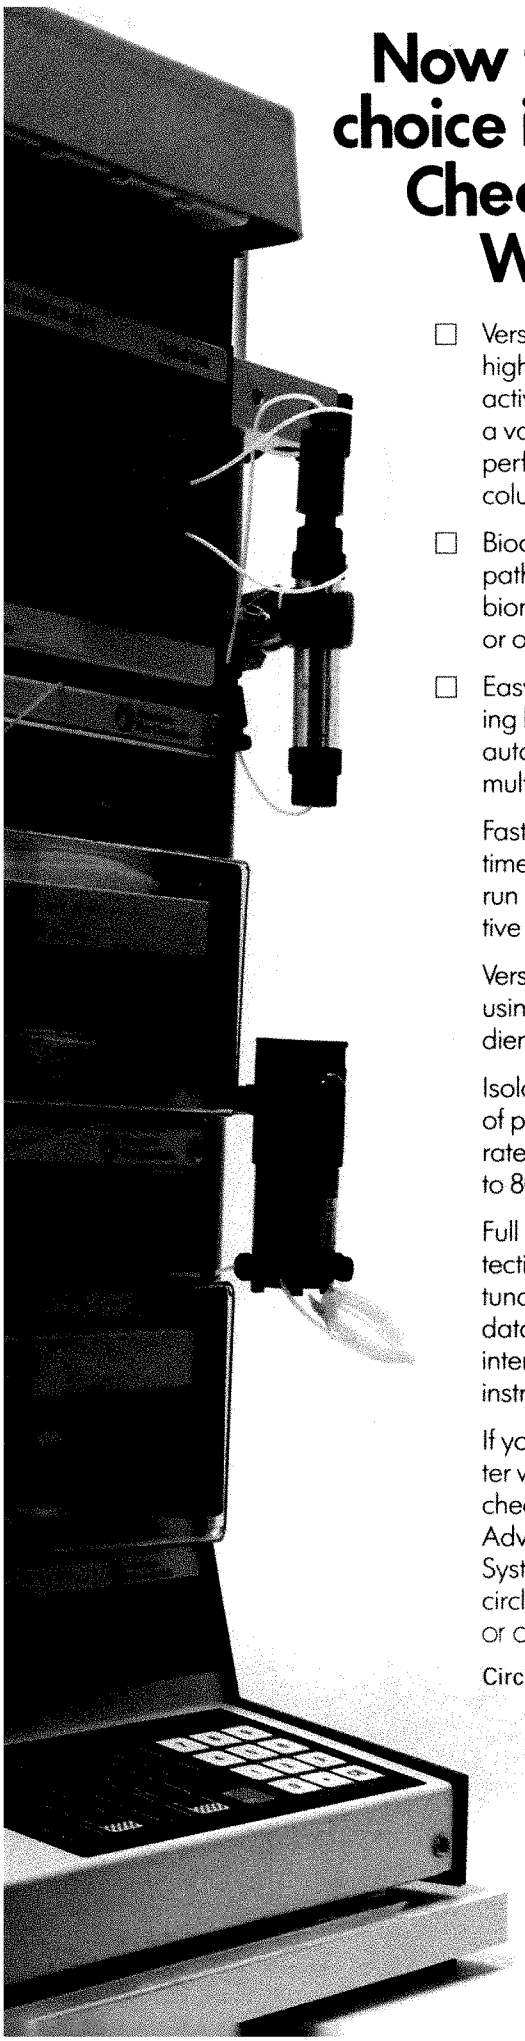
A NEW kit from **Serotec** offers the researcher a sensitive and simple method for determining the class/subclass of their monoclonal antibodies, at moderate price. The test system is based on red-cell agglutination technology and will eliminate the use of lengthy ELISA procedures or immunodiffusion techniques. Each kit contains sufficient reagent for the complete characterization of at least 30 monoclonal antibodies. *Reader Service No. 586.*

CHROMATOGRAPHY



RECENTLY launched by **Life Science Laboratories** is a new dual purpose in-line detector which can simultaneously monitor both *p*H and ionic strength at the outlet of a chromatography column. This instrument has been designed to be compatible with high or low pressure, analytical HPLC or preparative systems. Working temperature range is 4-40°C, making it ideal for cold room operation. *p*H is monitored from 2 to 12 *p*H units. Conductivity is linear from 0 to 100 mS corresponding to 0-1.35 M NaCl. The *p*H/ion meter can monitor both the gradient profile and elution molarites, providing immediate information as to when re-equilibration is complete. Safety and ease of use are facilitated by separation of the fluidics from the electronics by an interconnecting cable. The instrument comes complete with monitors, *p*H probe, conductivity and *p*H cells, cables and all necessary liquid fittings. *Reader Service No. 585.*

pH/Ion monitor from Life Science Laboratories.



THE latest high-performance amino acid analyser is now available from **Beckman,** in the form of a dedicated liquid column chromatograph. The system 6300 performs automated ion-exchange chromatography with ninhydrin detection to provide the precision analysis standards required for high speed, high resolution separations of hydrolysate and physiological samples. An on-stream post-column ninhydrin derivatization facility, which eliminates a sample preparation step and permits increased quantitation accuracy, assures the instrument's repeatability. High resolution is influenced by features such as the microvolume reactor and microbore tubing of the System 6300. A touch of the keys on the System 6300 panel allows selection of a pre-programmed method or entry of new parameters. Up to four methods can be stored and extra methods can be retained on Beckman's Memory-Pak cassettes. A real-time visual display shows flow sequence, operating temperatures and pressures. Panel key pressure directs the system to measure flow rate. *Reader Service No. 584.*

Super packed capillary column from Phase Separations.

LIQUID chromatography of unstable substances has been simplified further with the new BAS 200A gradient LC system from **Biotech Instruments.** The BAS 200A provides rigorous deoxygenation, ensuring minimal baseline drift for critical low wavelength UV gradient separations and reductive mode electrochemical detection. High sensitivity (0.0005 AUF) variable wavelength UV/Vis and multi-electrode electrochemical detection are among the multiple detection configurations available, with data reduction capabilities for up to four external detectors. The ternary gradient solvent delivery system does not require pulse damping. Pump heads are easily removed and are interchangeable, allowing simple preventive maintenance. A forced air oven accommodates most column formats, and ensures optimum precision. A refrigerated autosampler is available. *Reader Service No. 583.*

Now there's a better choice in fast protein LC. Check out the new Waters 650.

- ☐ Versatile LC system gives fast, high resolution separations of active biological materials using a variety of standard and high performance chromatography columns and media. ☐
- ☐ Biocompatible, non-metallic fluid path is non-reactive with labile biomolecules. Unaffected by salt or organic buffers. ☐
- ☐ Easy to maintain, non-intimidating hardware, with manual or automated control of simple or multi-step purification protocols. ☐
- Fast, error-free set up and real time monitoring of system and run conditions using an interactive CRT display. ☐
- Versatile methods optimization using linear or non-linear gradients with up to four solvents. ☐
- Isolation of micrograms to grams of purified protein using flow rates from 0.1 to 45 ml/min (up to 80 ml/min optional). ☐
- Full range of UV wavelength detection options—programmable, tunable, or fixed. Wide choice of data options, with the ability to interface with other Waters instrumentation. ☐

If you're looking for a faster, better way to do protein purification, check out the new Waters 650 Advanced Protein Purification System. For more information, circle the Reader Service Card, or call 0923 816375

A NOVEL solution to the problem of low efficiency of conventional GC columns has been recently introduced by **Phase Separations.** Their Super Packed Capillary Column (SPCC) comprises 0.53mm ID silica tubing hexagonally close-packed with 100-μm diameter mono dispersed porous silica. This configuration of column approaches 6,000 theoretical plates per m for many phases, according to Phase Separations. The use of porous silica to support the bonded phase permits up to 10% higher phase loading and a wider choice of phases. Mixed phases are also possible. The Spherisorb GC packing has low impedance to gas flow and large surface area. *Reader Service No. 582.*

THE introduction of the CCS Model 10000 High Pressure Supercritical Fluid Chromatograph (HPSFC) has been announced by **Severn Analytical Ltd.** The CCS Model 10000 extends the operating range of currently available supercritical fluid chromatography from a maximum operating pressure of 6,000 p.s.i. to 10,000 p.s.i. This increase in operating pressure offers the chemist an advantage in the analysis of thermally labile analytes of high molecular weight which cannot be successfully analysed by GC or HPLC or low pressure SFC techniques. The CCS Model 10000 HPSFC extends the useful range of SFC into entire classes of compounds which are marginally soluble at 6,000 p.s.i. Severn Analytical offers two systems for HPSFC, the new model 10000 and the model 7100 Controller/ Fluid Delivery System. Current users of CCS Model 5000 and 7000 systems can be upgraded to HPSFC capability by contacting Severn Analytical about a cost effective upgrade package. *Reader Service No. 581.*

Severn Analytical's Model 10000 HP Supercritical Fluid Chromatograph.

ACCESSORIES

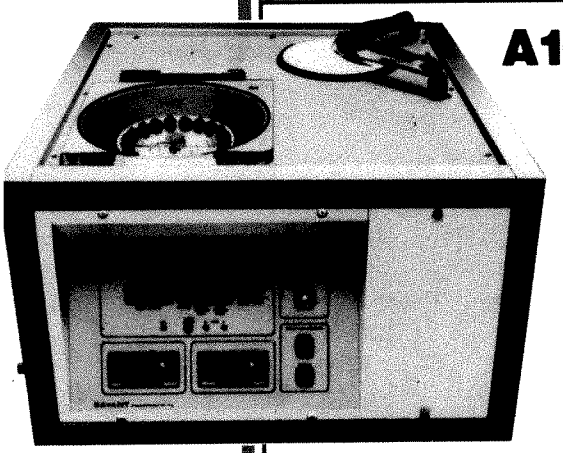
LABORATORY staff are increasingly having to wear gloves for extended periods. As a direct result of this many are experiencing some sensitivity or allergic reaction, associated with the chemical accelerators used in the manufacturing process of the gloves. Reaction can also result from the caulk or cornflour dusting powders, used to assist in donning of gloves. Hand 'Pro-Tect' from **Sentinel Laboratories** helps to overcome the problem by forming an invisible protective barrier over the hands. This also reduces transpiration and helps to maintain the skin's natural *p*H, hence inhibiting the build-up of bacteria. Supplied as an aerosol barrier foam, Hand 'Pro-Tect' is applied before donning gloves. The product has a neutral smell, is rapid drying and provides protection for up to 4 hours. The barrier is easily removed with soap and water leaving the hands lightly moisturized, helping keep the skin in good condition. *Reader Service No. 580.*

Soft as silk, Sentinel glove liners.

SENTINEL **Laboratories** also produces Sensi-Touch glove liners, designed to overcome the problem of allergy or reaction to latex examination or surgeons' gloves. Sensi-Touch glove liners maintain a high level of tactility whilst providing protection to the user. The liners provide a fine, positive barrier between the hand and the latex glove; protecting from both dusting powder and chemical accelerators used in the glove manufacturing process. An added benefit of Sensi-Touch, is the absorption of perspiration from the hand, facilitating delicate work. Manufactured from fine, Milanese pure silk, Sensi-Touch liners cause no adverse reaction to most sufferers of skin sensitivity. The liners are re-usable and the fine silk fabric can be rinsed through as required. *Reader Service No. 579.*

Synthesis to order

A SERVICE for the synthesis of oligonucleotides is now offered by **LEP Scientific.** A high purity product is guaranteed which will produce good yields of the target product. Custom synthesized oligonucleotides may be purchased from LEP Scientific either on a contract basis or by standing order. In-house monitoring ensures that each product will perform correctly, but in addition LEP Scientific will provide customers with a sample for testing, prior to the contract date. LEP Scientific also offers a wide range of purified oligonuleotide probes and primers for DNA sequencing, cloning and hybridization; enzymes and Taq polymerase. *Reader Service No. 578.*



BUFFERS

AN extensive range of biological buffers is produced by **Calbiochem** at competitive prices. Ultrol Grade Buffers are produced to the most stringent specifications for use in biological systems. They are screened for uniform particle size, giving uniform solubility characteristics. The range includes BES, Bis-Tris, HEPES, MES and Tris. The Calbiochem technical monograph *A Guide to the Preparation and Use of Buffers in Biological Systems* is available free from Novabiochem (UK) Ltd. *Reader Service No. 577.*

BACTERIAL TESTS

A RECENTLY introduced latex slide test from **Cambridge Biomedical** has been developed to identify haemolytic streptococci rapidly and simply. Strepslide identifies streptococci in Lancefield's groups A,B,C,D,F and G, the six most clinically important strep groups. The test uses an enzyme which is specially formulated to extract the group-specific cell-wall polysaccharide. Antigen in the resulting extract is identified using polystyrene latex particles which have been coated with group-specific antibodies raised in rabbits. These latex particles agglutinate strongly in the presence of homologous antigen and remain in smooth suspension in the

Savant

A160 Concentration Station

SpeedVac A160 benchtop concentration station for laboratories requiring versatility and precision — Automatic sequencing concentrates up to 100 samples simultaneously and identically run after run. Eliminates variants and sample loss. Processes samples at optimum temperature for pre-set dryness, rapid concentration and consistent results.

Wide choice of rotors for a broad range of applications for both aqueous and organic solvents.

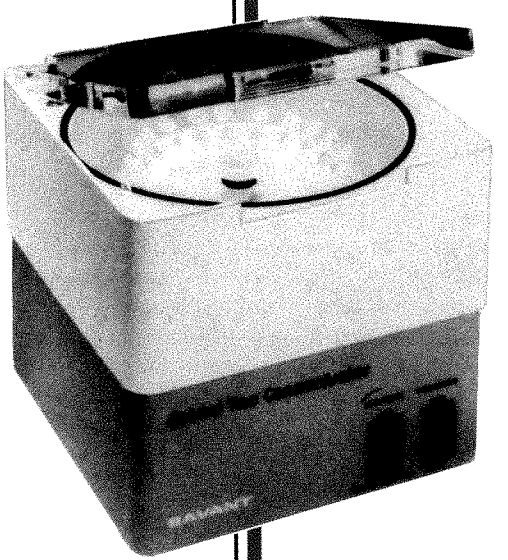
Where space is limited and efficiency and consistency are required, SpeedVac is the answer.

Speed Vac Concentrator-Evaporator

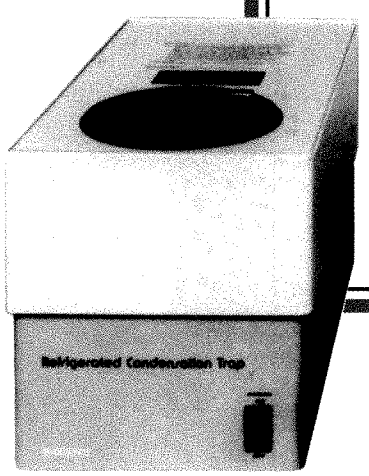
Centrifugal action combined with high vacuum gives rapid and highly efficient sample recovery.

Several models are now available including robotically controlled and completely integrated systems.

23 different types of rotor accepting a comprehensive range of tubes, microtiter plates and flasks, with sample volumes up to 250ml.



Applications



For Preparation and High Recovery of:

- DNA • RNA • Proteins • Peptides • Amino Acids
- Hormones • Enzymes • Drugs

For Analysis by:

- Radioimmunoassay – RIA • Enzyme Immunoassay – EIA
- Fluorescent Immunoassay – FIA • TLC • FPLC • HPLC
- GC/MS • IR • UV • Electrophoresis

Refrigerated Condensation Trap

Ultra-Low temperature

Low Temperature (–60°C) and Ultra Low Temperature (–104°C) models available in various sizes and capacities. With either glass or stainless steel collection reservoir.

STRATECH SCIENTIFIC LTD

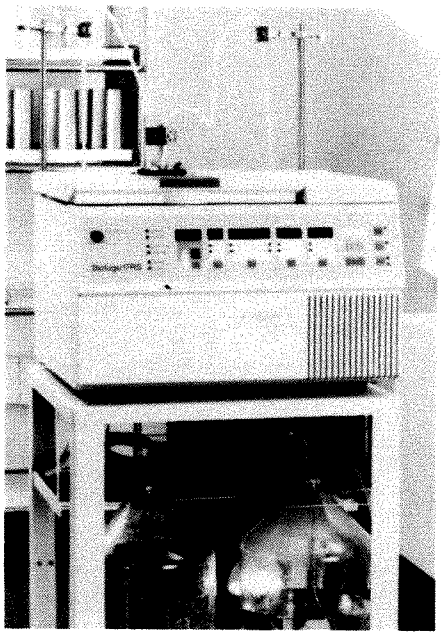
Circle No. 406 on Reader Service Card

absence of homologous antigen. Strepslide comes in a complete ready-to-use kit; a rapid 10-minute enzyme extraction means that results can be obtained from primary plates in less than 15 minutes. Disposable test cards make the product convenient to use, as well as having important safety considerations. The stable extraction enzyme used requires no reconstitution, and freezing is unnecessary. It is said to give very good specificity, showing excellent correlation with traditional extraction methods. *Reader Service No. 576.*

AN advance in chlamydial antigen detection has recently been achieved by **Northumbria Biologicals Ltd.** AntigEnz Chlamydia, the new *Chlamydia trachomatis* 'one-step' EIA combines very high test sensitivity with speed and simplicity. Total incubation time is 90 minutes and the assay includes only one washing step. The test uses a monoclonal antibody to ensure accurate and reliable results. AntigEnz Chlamydia is designed for convenience, the microwell format enables the operator to use only that portion of the kit required at any one time. Each kit comes complete with 95 vials of transport medium, ready dispensed. *Reader Service No. 575.*

AS the present controversy over salmonella poisoning continues, additional new aids have been introduced which reduce the cost and improve the accuracy and speed of detecting the bacterium in all types of food products and animal feedstock. Two new types of kits are now available through **Dynatech Laboratories.** The first kit is

Salmonella test kits from Dynatech.



Materials test

WHEN Laura Ashley decided to replace the Xenotest 150 it uses to test fabric for light and weather fastness, it turned to the same manufacturer again – **Heraeus Equipment.** Heraeus has now supplied Laura Ashley with a Xenotest 150S model, which is being used at its Powys production unit. It can test samples up to 13 cm × 4.5 cm in size and expose them on both sides of ten rotating holders. The Xenotest 150S tests materials for both light and weather fastness. Its principal attributes include ultrasonic humidification, digital indication of test conditions plus temperature and humidity control. *Reader Service No. 570.*

the Biocontrol 1-2 test. It is a fast, inexpensive and easy-to-use kit which increases the viability for farmers and manufacturers alike to undertake salmonella testing on site. No special laboratory equipment is required. Samples are placed on a simple, disposable, twin chamber device which can be set up in less than two minutes. A culture is grown and positive results are clearly displayed in as little as 32 hours. Once the test has been inoculated, further spreading of the microorganism through cross contamination is prevented. The second test has been developed for use in centralized laboratories. Called Q-Trol, it offers high throughput of samples with great reliability. Said to be faster than any other method currently available, Q-Trol is used to determine the nature and extent of salmonella infection. Laboratory technicians can now run up to 92 tests simultaneously in just 2½ hours. *Reader Service No. 574.*

CENTRIFUGATION

A CONTINUOUS flow centrifuge which is portable and can be used on a benchtop has been developed by **Heraeus Equipment.** In the development of the Contifuge 300 MD, Heraeus has applied the latest innovations in centrifugation technology and, as a result, the rapid and simple separation of bulk products has become a practical proposition. The centrifuge is based on a continuous flow rotor, HCT 22.3000, which operates in a refrigerated or non-refrigerated benchtop high-speed centrifuge. It features a sediment capacity of 300 ml and a *g*-force of approximately 19,000. The unit is quiet and features Sepacontrol — Heraeus's easy to use, state-of-the-art microprocessor control panel with digital display. This in-built microprocessor enables users to pre-select and store 32 centrifugation programs in the memory. *Reader Service No. 573.*

New standards in centrifugation with Heraeus' Contifuge 300 MD.

NEED to centrifuge in bulk? **Jouan Ltd** has produced possibly the world's largest centrifuge bottle for use in its LR5.22 large capacity refrigerated centrifuge. The new 1,600 ml bottle is made of polycarbonate for clarity and strength, is autoclavable and has a positive screw cap for containment. As a result the Jouan LR5.22 now offers an increase from 6 to 9.6 litres per run. In addition, the new KR4.22 floor-standing centrifuge can spin 6.4 litres (4 × 1,600 ml) or 6 × 1 litre. Both instruments can achieve a powerful 7,300*g* with the largest single sample volume containers on the laboratory market today. *Reader Service No. 572.*

AVAILABLE in six colours to aid identification of samples and/or work patterns are the 1.5 ml Microcentrifuge Tubes from **Laser Laboratories.** These leakproof polypropylene tubes have flexible caps which are easily removed one-handed, yet are secure in their fit. The caps have a smooth flat surface upon which labels or identification marks can be written. *Reader Service No. 571.*

THE range of accessories for the new C3 series mid-capacity benchtop centrifuges from **Jouan** has now been increased by the addition of microlite plate carriers. The Jouan C3.12 and refrigerated CR3.12 can spin the carriers on the standard rotor, saving money, time, storage and potential rotor damage. A full load of eight plates is larger than normal for a machine of this type. C3 series centrifuges come with a range of 24 inserts for different tube types and microscope slides, swing-out and 4 angle rotors. With high capacity, low price and 3,600 r.p.m., the C3 is particularly suitable for the path lab. *Reader Service No. 569.*

Eagle Scientific's ozone friendly refrigerated centrifuges.

REFRIGERATED centrifuges from **Eagle Scientific** are now ozone friendly. The company's new range of refrigerated centrifuges have solid state refrigeration units, with no risk of leaking refrigerant; maintenance and repair problems associated with compressor refrigeration systems are also eliminated. Temperatures down to 2°C are available, set to within 0.1°C by means of a simple digital temperature display/control. Machines are available with capacities up to 2 litres and speeds up to 11,000 r.p.m. *Reader Service No. 567.*

THE launch of the Biofuge 17RS centrifuge by **Heraeus Equipment** has provided the market with a benchtop unit with the facility to accommodate 98-ml test tubes. The 17RS also features refrigeration and is progammable from −19 to +40°C. Heraeus applies the highest safety standards in the manufacture of all its centrifuge models. The Biofuge 17RS unit features automatic lid-lock to prevent the lid from opening before the rotor stops, cuts out automatically if its drive or refrigeration units are overloaded, if a sample overheats or if any imbalance occurs during operation. Sepacontrol, Heraeus's easy to use microprocessor control panel with digital display, is another feature of the Biofuge 17RS. This in-built microprocessor enables users to pre-select and store 32 centrifugation programs in the memory. *Reader Service No. 566.*

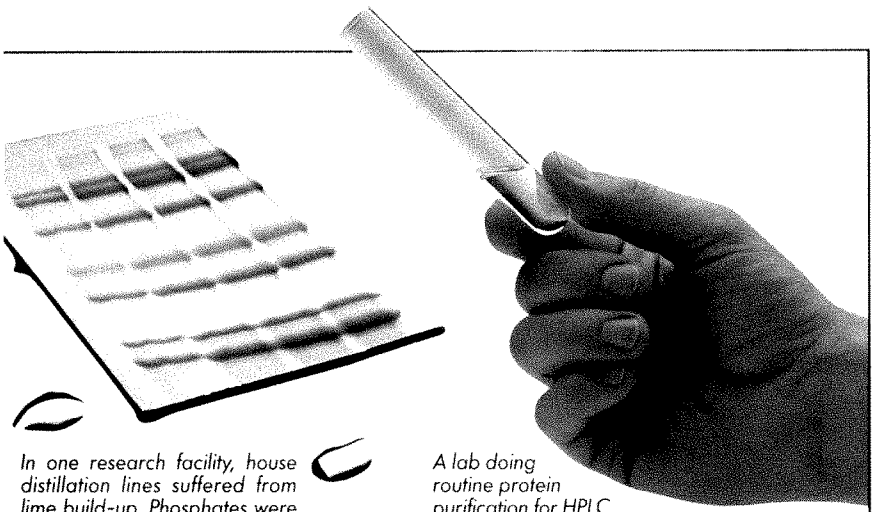
THE Mistral range of microprocessor-controlled centrifuges offers a choice of configurations to suit a wide range of applications. **MSE's** automatic rotor identification, a feature of all Mistral centrifuges, enables these instruments to display actual RCF without the need to input rotor radius information. Automatic rotor identification also prevents the possibility of an overspeed condition as a result of inputting a wrong maximum speed, an important safety consideration. The Mistral 1000 (4 × 100 ml) and Mistral 2000 (4 × 200 ml) both combine a touch-sensitive keypad and an interactive liquid crystal display to provide rapid and accurate setting of run parameters, including the ability to run to RCF. With six-litre capacity, the Mistral 6000 is top of the range of MSE centrifuges. It can take up to 360 samples in one load. *Reader Service No. 565.*

Mistral 1000 and 2000 centrifuges.

Seal of approval

THE sealed buckets for **MSE's** new Mistral centrifuges have been approved for containment of pathogens. Compatible with Mistrals 3000E, 3000i and 6000, the sealed buckets have a capacity of 750 ml (Mistral 3000) or 1 litre (Mistral 6000) and are suitable for use in clinical or other applications involving centrifugation of hazardous samples. Up to six sealed buckets can be loaded into the swing-out rotor of the floor-standing Mistral 6000, while four can be accommodated by the Mistral 3000 advanced benchtop centrifuges. *Reader Service No. 568.*

AUTOSAMPLING

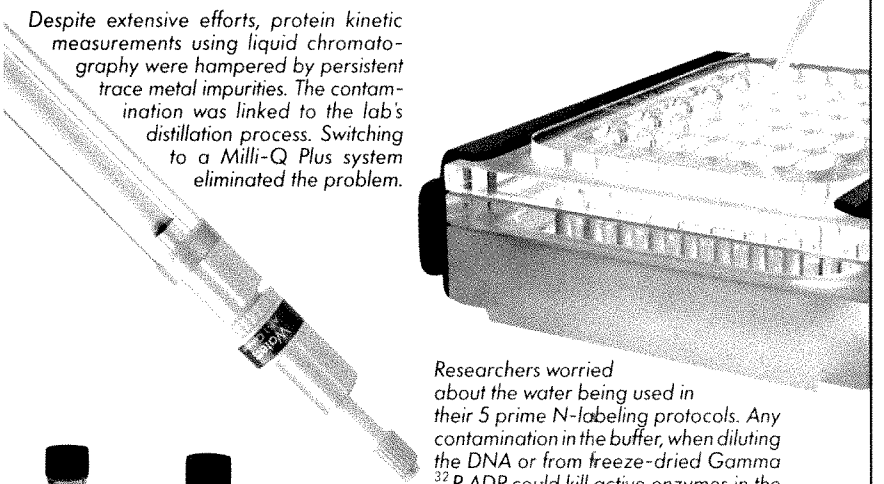


THE 8-PEC1 is a low cost, plastic cap designed to fit all **Chromacol** 8mm OD vials. The cap is made from low cost polyethylene, making the price of the 8-PEC1 very competitive. In addition, the 8-PEC1 is a snap-fit and does not require any tools to affect a seal on the vial. The 8-PEC1 is compatible with Chromacol's 02-MTV, 03-CVG, 06-CTV(A), 08-CRV(A), 08-CPV(A), 1-CRV(A), 1-CWV, and the 1.2-CWV vials. It can also be used with a wide variety of autosamplers, details of which are included in the latest edition of the Chromacol catalogue. *Reader Service No. 564.*

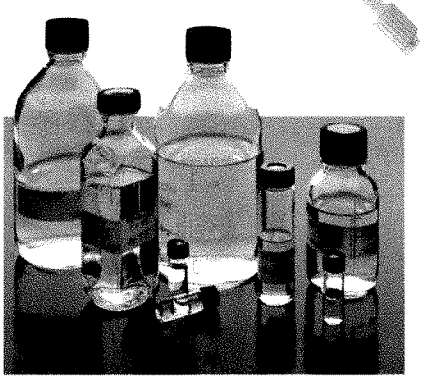
HPLC

A HIGH-PRESSURE pump with built-in software that controls analytical and preparative HPLC systems has been introduced by **Gilson Medical Electronics.** The new Model 305 pump communicates with as many as three other Gilson pumps to generate mobile phase gradients in a broad working range (0.025 µl to 200 ml min^{-1}, 60 MPa). The 305 is compatible with low *p*H and high salinity. For more sophisticated system automation, the 305 pump connects easily to a computer running Gilson's 714 HPLC System Control and Data Analysis software package. Programmable contact inputs and outputs provide time-regulated control. Up to 10 sets of control parameters can be stored in non-volatile memory, together with up to four fail-safe programs to protect unattended operations. The 305 pump is compatible with all Gilson pump heads, including a new 200 ml min^{-1} titanium head designed for preparative biopolymer separations. Flow rate precision and low pulsation are ensured during mobile phase delivery as the pump electronically compensates for changes in compressibility. *Reader Service No. 563.*

THE Shimadzu SIL-9A standalone auto-injector is now available from **Dyson Instruments** at reduced cost due to accelerated production at the Shimadzu factory in Japan. The SIL-9A features a sample rack that accepts six types of sample vials and a sampling needle that moves in *x*, *y* and *z* directions, permitting random access to different vials. This allows various types of sample pre-treatment, including sample

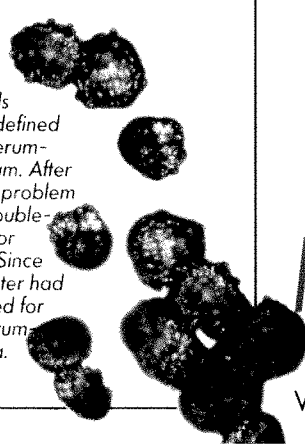


Distilled water: not always the right solution.



In one research facility, house distillation lines suffered from lime build-up. Phosphates were used to clean the system and got into the water used to make polyacrylamide gels, preventing the gels from running. The problem was alleviated when the lab switched to a Milli-Q Plus system.

A lab doing routine protein purification for HPLC couldn't account for protein contamination until they checked their double-distilled water. Trace levels of endotoxins were adhering to glassware. They replaced the still with a Milli-Q Plus pyrogen-free system, which solved the problem.



Despite extensive efforts, protein kinetic measurements using liquid chromatography were hampered by persistent trace metal impurities. The contamination was linked to the lab's distillation process. Switching to a Milli-Q Plus system eliminated the problem.

Researchers worried about the water being used in their 5 prime N-labeling protocols. Any contamination in the buffer, when diluting the DNA or from freeze-dried Gamma ^{32}P ADP could kill active enzymes in the T4 polynucleotide kinase. A Milli-Q Plus system increased the viability of these enzymes.

Waterborne endotoxins and pyrogens were contaminating reagents manufactured by an in-house supplier. The contaminated reagents, in turn, delayed the work of four research groups who relied on the supplier for reagents and pre-cast gels. A pyrogen-free Milli-Q Plus system got things back on schedule.

Researchers found their mammalian cells stopped growing in defined medium, but not in serum-supplemented medium. After thorough review, the problem was linked to their double-distilled water used for media preparation. Since then, Milli-Q Plus water had been successfully used for both defined and serum-supplemented media.

It's getting so you can't trust distilled water. Parts per thousand contamination levels used to be adequate, but with today's ultra-sensitive equipment, low part per billion levels are almost mandatory.

The Milli-Q® Plus system eliminates ions, pyrogens, and organics that even 5x distilled water can't. And it's easier to use.

The new, redesigned all-in-one cartridge pack takes ten seconds to change. Just pop out the pack and pop in a new one. The system even tells you when to do it.

Because there are no bowls, the system has virtually no hold-up volume, resulting in faster flush-ups, reduced extractables and bacterial growth.

The configuration of the system makes it the smallest on the market, so you can save bench space.

It comes with "on-demand" flow and automatic recirculation, which eliminates storage and degradation problems.

There's also an easy-to-read alpha-numeric display, PVDF valves to prevent leaching, and a Millipak® 0.22 µm pharmaceutical grade final filter.

For more information, call **(0923) 816 375**, and find out why over 9000 scientists choose Milli-Q water for trouble-free research.

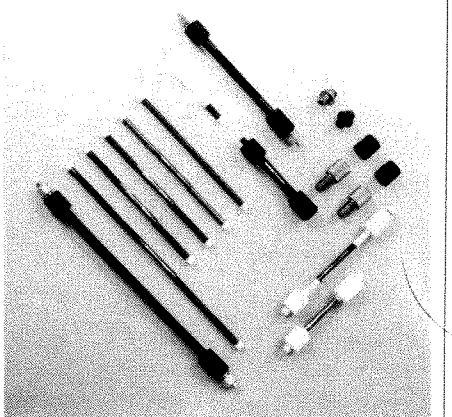
HPLC training

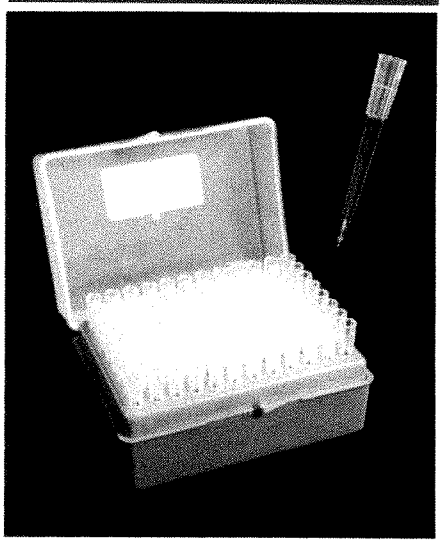


A BASIC training course for HPLC has been introduced by **Severn Analytical.** This complements their existing course for users of the Coulochem Electrochemical detector and is designed for beginners to chromatography. The course runs over a 2-day period and covers all aspects of HPLC with a grounding in the fundamental principles. Practical experiments are designed to reflect the theoretical lectures and tutorial sessions are aimed to ensure that each topic is clearly understood. *Reader Service No. 562.*

dilution, addition of internal standard and pre-column derivatization, before samples are automatically injected onto the column. The SIL-9A is said to be compatible with any make of HPLC. *Reader Service No. 561.*

THE capabilities of **Beckman's** System Gold HPLC package are further enhanced by the introduction of a new family of autosamplers which operate on-line as part of System Gold or stand alone within other chromatography systems. The autosamplers allow precise but versatile injection protocols and significantly enhance HPLC automation. Sampling conditions can be programmed as part of the complete analytical method and stored on disk. When analytical results are out of the expected range, the sample can be automatically reinjected and reanalysed. Operating features include a four-quadrant, refrigerated sample holder with 96-vial capacity and a separate vial for rinse liquid. Vial access is direct so that calibration vials need not be in sequence. Column temperature control is also available. The 507 module offers variable injection volumes from 1 to 999µl, pre-column reagent addition, mixing and reaction and column switching. *Reader Service No. 560.*

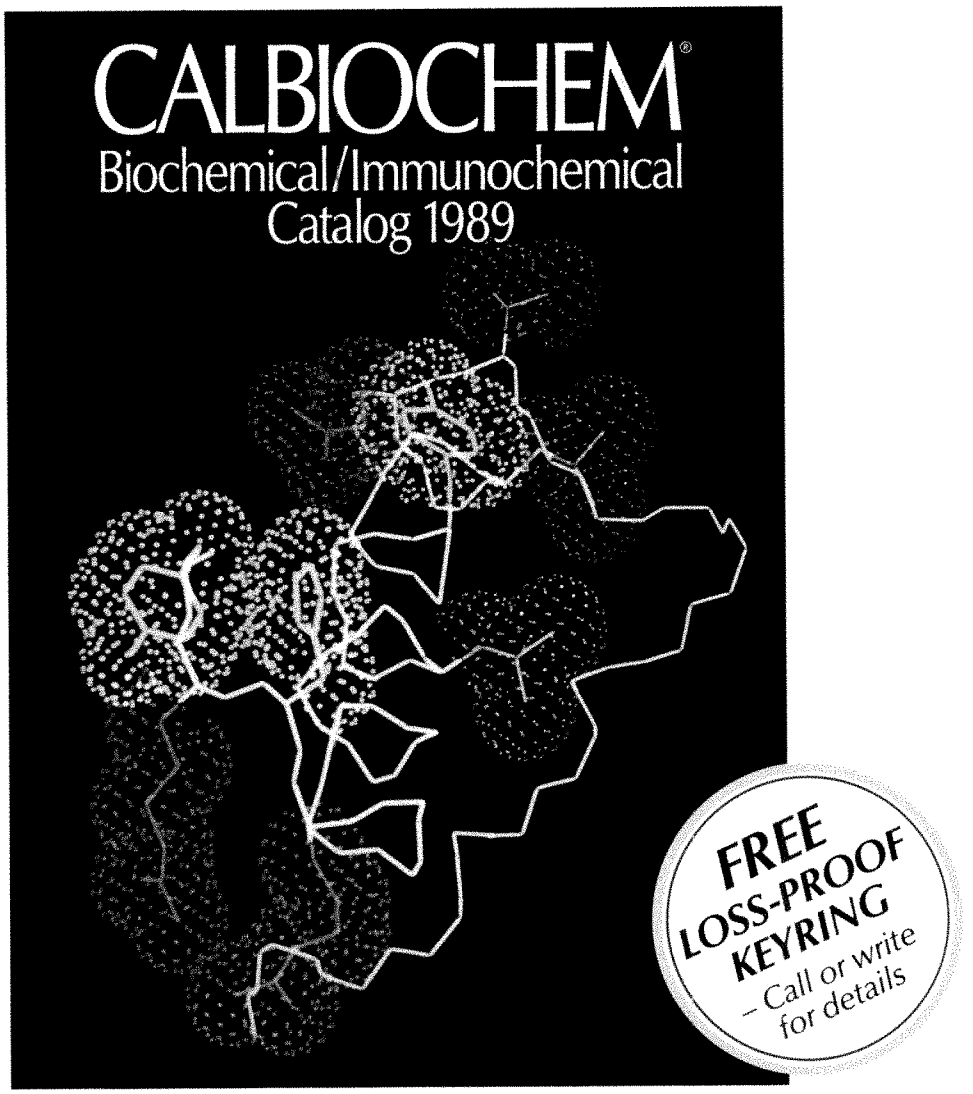
ALSO from **Beckman** is a configuration of System Gold for radiochromatography; possibly the first radiochromatograph to combine all HPLC components as a single integrated system package. The system unites two fully programmable detectors: the Beckman Model 166 for detection of the UV/Vis absorbing compounds, and the Beckman Model 171 for detection of radioisotopes such as H3 and C14. The system includes the new on-line Beckman Model 507 autosampler. Following the pattern of System Gold development, this latest system offers radiochromatographers improved facilities for instrument control, data handling and record maintenance. All system components are linked on a bi-directional digital communications network. *Reader Service No. 559.*



A NEW HPLC column and cartridge system called Ulti-Mate is available from **LEP Scientific.** The Ulti-Mate system provides the chromatographer with a fast, simple to use and versatile column and cartridge package which overcomes many of the inherent disadvantages of existing systems. Column and cartridges are available for analytical, narrow, microbore and preparative HPLC. The Ulti-Mate columns and cartridges are colour-coded for clear identification of the packing media. The finger tightened Ulti-Mate universal end-fitting connector achieves a seal at pressures up to 6,000 p.s.i. without the need for tools, and may be connected to all conventional end-fitting systems. This system ensures that cartridges can be changed more quickly, which is of particular value for guard columns. The Ulti-Mate microbore systems offer cost savings without loss of resolution. In addition, titanium columns, cartridges and frits are available (glass lined) to provide the environment where protein denaturation is minimized. The entire range of Ulti-Mate columns and cartridges is available in titanium and glass-lined metal as an option to the stainless steel (316 grade) supplied as standard. *Reader Service No. 558.*

Ulti-Mate HPLC columns and cartridges from LEP Scientific.

THE costs of peptide analysis and purification can be reduced using the new high efficiency 5µm 300A spherical particle Dynamax HPLC columns from **Anachem.** These chemically stable columns are available in C4, C8 and C18 versions, with short 5-cm columns for rapid separations or 25-cm columns for high capacity, high resolution separations. With 4.6, 10, 21.4 and 41.4mm ID options you can use Guaranteed Linear Scale-Up™ to preparative columns following method development on the 4.6mm ID column. *Reader Service No. 557.*



LIQUID HANDLING

THE new Premier tip has special features to please the most fastidious liquid handler, according to **Laser Laboratories.** Made of high grade non-wettable virgin polypropylene, the tip has a tapered end which aids fluid drainage and allows access to the bottom of the narrowest tube, even a microcentrifuge tube. The tip has found considerable acceptance in paediatric sampling, and gel loading where volumes of 5 or 10 µl are common. Access and loading of small wells in gel plates is easier. The 'Premier' tip is natural (white) in colour, has a certain transparency, which may benefit sample inspection whilst pipetting, and has an overall length of 52 mm. The tip can accommodate up to 200 µl, and fits Gilson Pipetman, Rainin, Finnpipettes, Eppendorf, Socorex and Titertek pipettes. *Reader Service No. 556.*

BECKMAN has recently introduced a 96 Deep-Well Titre Plate for micro-assays such as ELISA, hybridoma, minimum inhibitory concentrations (MICs), DNA

Always the Highest Quality. Now the Best Value, too.

Call now for your free 1989 Biochemical/ Immunochemical Catalogue containing hundreds of new listings.

It's just what you would expect from Calbiochem, an independent corporation with a reputation for quality based on nearly 4 decades of research.

Top quality, state-of-the-art biochemicals and immunochemicals. Plus a free, fact-filled 2,500 listing source book to help you pick the right ones for your research.

You get detailed specifications. Application information. Bibliographies. An alphabetical index and immunochemicals grouped in a systems approach. It's easy and efficient to use.

Calbiochem's new U.K. distributor offers you a Great New Deal.

- Next-day Delivery on most items.
- Full technical support.
- Value-for-money prices.
- No minimum order.
- Free delivery.

sequencing and receptor binding studies. They also have uses in the pharmaceutical industry and in many biotechnology and bioresearch applications. The new 96-well plate has a single-well capacity of 1 ml capped or 1.2 ml uncapped. A 96-cap cover strip provides the means for convenient storage, and for stacking during incubation. Manufactured in polystyrene and supplied non-sterile, the 96-well plate is available in boxes of 25 plates, with caps in packs of ten. The plates are compatible with single-, eight- and twelve-tip pipettors. *Reader Service No. 555.*

A 5-ml Macro Tip is also available from **Laser Laboratory Systems.** The tip is 148 mm in length and fits most Macro pipettes. Its diameter is 10 mm at the 'shoulder' end which allows access to narrow receptacles such as tissue culture flasks, volumetric flasks and tubes. The graduations are moulded into the virgin polypropylene surface of the tip in 0.1-ml increments, giving instant visual verification of volumetric accuracy when pipetting. The orifice of the new Laser Tip is wider than most, preventing bubbles and frothing of liquids when a full 5 ml is taken in by the pipette. *Reader Service No. 554.*

Laser's Macro Tip features graduations.

A RANGE of round-based tubes from **Sentinel Laboratories** is compatible with the standard instrumentation in both blood banking and clinical chemistry. Manufactured from high quality, virgin, crystal polystyrene and also in polypropylene, the tubes suit all applications. Initially available in 10 × 64 and 12 × 75 formats, all tubes are rigorously quality controlled throughout the factory, from raw materials through to dispatch. Also available are tight fitting, leakproof push-fitting caps. The caps are supplied in a range of colours for sample coding purposes. *Reader Service No. 553.*

Tubular belles from Sentinel.

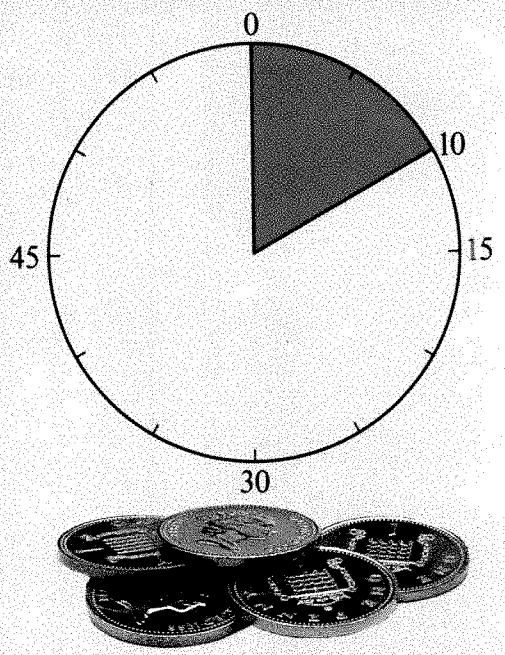
A HIGH technology pipettor replaces other existing types, claims manufacturer, **Jencons Scientific.** Adjustable keys on the pipettor body allow more than 70 different standard volumes to be set; the range covers 0.5 to 5,000 µl. Simple volume adjustor keys are colour-coded to help speed volume changes. Called Sealpette Clinical, the series is manufactured in varnished Novodur plastic to a fine finish. Other Sealpettes in the range include the Fixed Economy, Variable and Universal. *Reader Service No. 552.*

Jencons adjustable pipettor.

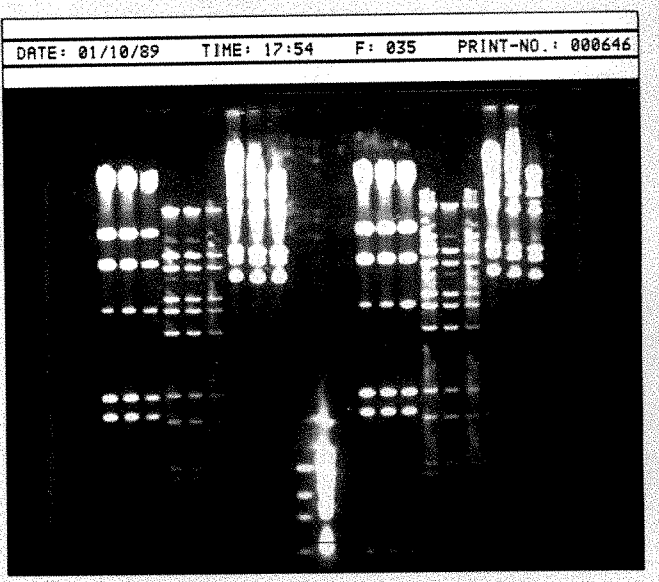
Fermentation facility

JOHN & E Sturge has a wide range of fermentation vessels ranging in size from 100 to 45,000 litres for hire. All the equipment is fully manned and supervised and can be hired for any length of time — from two or three days up to several months. Downstream processing facilities are also available for isolation and purification of Biotechnology products. *Reader Service No. 550.*

"CUBE 2ubes" from **Beckman** are available as 2 ml cube tubes for microassay work, including ELISA, hybridoma, minimum inhibitory concentrations (MICs), DNA sequencing and receptor binding studies. Offered with a choice of sterile or non-sterile packaging and in polypropylene or polystyrene, these disposable tubes are available in a standard 96-well format. Cube 2ubes are packaged in 20 racks each of 96 tubes. Sterile and non-sterile caps are also available, packed in 12-cap strips, 80 strips per carton. *Reader Service No. 551.*



INCUBATORS



A NEW range of economic, high specification slimline cooled incubators has been introduced by **LEEC.** Called the LT series, these incubators use a new temperature control system (patent applied for) which overcomes the need to defrost the units. This system is capable of controlling chamber temperature to an accuracy better than +/ –0.1°C over the range 0 to 50°C by blending airflows between hot and cold ducts. The incubators feature LED digital temperature display together with over- and under-temperature safety thermostats which protect both incubator and chamber contents. Model LT3 is available with a working chamber volume of 215 litres. The chamber is constructed from easy-clean plastic with stainless steel ducting to give cleanability combined with durability. Four adjustable PVC-coated shelves are supplied. Disc and strip temperature chart recorders can easily be added. *Reader Service No. 549.*

OVENS

THE latest product from **Hybaid**, the Hybaid Hybridization Oven, is now available. The oven consists of a rotisserie unit, capable of rotating 12 bottles at a constant 5 r.p.m. within a high performance fan-driven oven. The oven is used to process blotting membranes derived from the Northern, Southern or Western process and both radioactive and non-radioactive probes have been successfully tested. The rotisserie approach is considered by many molecular biologists to be the most effective way of processing blots. Constant rotation ensures that pre-hybridization, hybridization and washing solutions are distributed evenly

THE GEL DOCUMENTATION SYSTEM FROM UVP

5 pence and 10 seconds later . . .

. . . UVP's new camera system produces:
A picture
A record
An analysis
. . . and that's not all

UVP's gel documentation system is the perfect solution for anyone who wants to create an easy-reference gel library at very low cost.

The system uses a video camera linked to a monitor. So you can get the exposure exactly right before you make your copy.

But you can do plenty more – enhance the image, analyse the gel and store all the information on disc.

And when you do make your copy it is produced, complete with comprehensive data band, in less than 10 seconds. And at remarkably low cost.

So get the complete picture by contacting us today for more information or to arrange a demonstration.

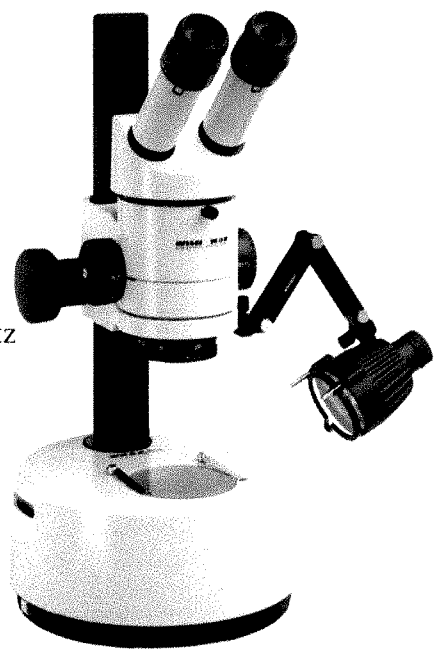
Could any stereomicroscope give results as good as this?



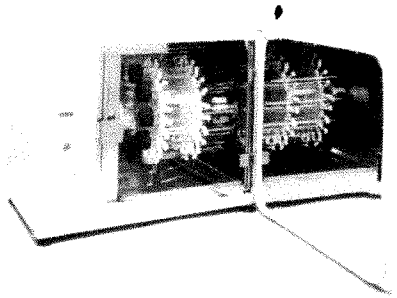
Any stereomicroscope couldn't – only those from Wild Leitz. They combine stereoscopic and vertical beam observation to give superb spatial imaging, high quality photomicrography and parallax – free measurement.

By effectively solving a design problem which is still inherent in lesser models, Wild Leitz have already opened many eyes to the versatility of such instruments as the Wild M3 series.

As a consequence, the M3 has become Britain's best-selling stereomicroscope. Of course, many other special features and exceptional Swiss quality have played their part.

But the paradox is the M3's price. Incredibly, it is competitive with ordinary stereomicroscopes – and you can hardly expect a better result than that.

Further details of the M3 range are available through **enquiry no. 415**. For a copy of the comprehensive new Wild Leitz Microscopy Catalogue, circle **enquiry no. 416**.



"The key criterion for the award of NHS supplies contracts is value for money taking all relevant factors of price, quality and service into account. Assessment of VFM includes concern with whole-life costs of equipment and hence with maintenance and running costs. In some circumstances this could mean that bids with the lowest initial prices are not always adjudged the most competitive in terms of overall VFM."

– from a statement of National Health Service procurement policy.

over the membranes and keeps probe volumes to a minimum, typically 10 ml for a 20 × 20 cm blot. The oven is accurate up to 90°C and can be used as an ordinary incubator if required. Hybaid also supplies a range of bottles for the oven and for other types of roller culture apparatus. *Reader Service No. 548.*

CELL CULTURE

TWO new cell production rollers have been developed by Bellco. The units increase capacity with only a modest increase in size, providing up to 86 positions for the long glass or plastic bottles, or 172 for the smaller bottles. To increase the safety of valuable cell lines, all units are equipped with solid state circuitry with digital display of rolling speed (0-3.0 r.p.m.) and all-position drive to ensure rolling of plastic bottles. Other options include motion alarm monitor and battery back-up drive. The units are available in the UK from **Arnold R Horwell Ltd.** *Reader Service No. 547.*

The Bellco High-Pro Roller.

SEQUENCING

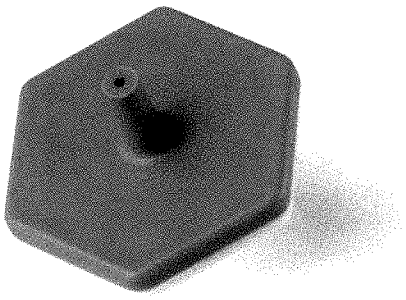
THE TaqTrack sequencing system from Promega is a new method for enzymatic sequence analysis which takes advantage of the intrinsic properties of the DNA polymerase isolated from *Thermus aquaticus*. The higher reaction temperature of the TaqTrack sequencing system decreases the secondary structure of the DNA templates and thus permits polymerization through highly structured regions. The system is useful for sequencing a wide variety of templates including amplified DNA, lambda DNA GC-rich templates and palindromic-rich templates. TaqTrack is marketed by **Stratech Scientific**. *Reader Service No. 546.*

ASSAYING

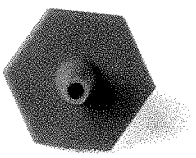
A BREAKTHROUGH in ligand binding assay design by **Amersham International,** has allowed a new technique that greatly simplifies ligand binding assays onto the market. There is no need to separate bound from free ligand or to use liquid scintillants for tritium detection. All assays can be performed and counted in one tube and are amenable to automation. The technology, called Scintillation Proximity Assay (SPA), consists of fluomicrospheres coupled with second antibodies or protein A. Fluomicrospheres are support bodies in the form of beads that are impregnated and/or coated with a material capable of fluorescence when reacted by radioactive energy. Amersham has used this concept to develop homogeneous 6-keto-prostaglandin F_1 [^{3}H] scintillation proximity assay (SPA) system, code TRK 952, and thromboxane B_2 [^{3}H] scintillation proximity assay (SPA) system, code TRK 951. Each of these systems provides equivalent results to those obtained using existing radioimmunoassays and can be performed following a one-day protocol or an overnight protocol. Amersham has also developed a series of generic scintillation proximity assay reagents for use by researchers in the conversion of in-house radioimmunoassays to scintillation proximity assays. *Reader Service No. 545.*

A NUMBER of new products have been developed recently by **Randox Laboratories** in the UK. The first is a kit for the measurement of superoxide dismutase (SOD). Called Ransod, the kit has only just become available. Randox anticipates that its use will be in clinical areas of interest, including copper status, hypocuprosis, Fanconi's anaemia and in heart transplant subjects. Also new from Randox is an ELISA for albumin, that the company claims offers advantages in the areas of precision, accuracy and wide working range. The kit is anticipated to be of particular interest in diabetic monitoring where it is capable of detecting very slight increases in urinary albumin excretion. *Reader Service No. 544.*

METACHEM Diagnostics Ltd is pleased to announce the availability of ^{125}I RIA kits for the measurement of human and rat α-atrial natriuretic peptide. Both assays are liquid phase competitive radioimmunoassays with separation of the antibody-bound analyte from the unbound analyte by BioMag magnetic separation. The assays give high sensitivity, the human α-ANP being sensitive to 2.2 pg per 0.1 ml and the rat α-ANP to 2.7 pg per 0.1 ml, with the standard curve range up to 200 pgμl^{-1}. The assays utilize high specificity antisera. Measurement of the peptides is easy to perform and procedural step accidents are reduced. *Reader Service No. 543.*



IMMUNOLOGY

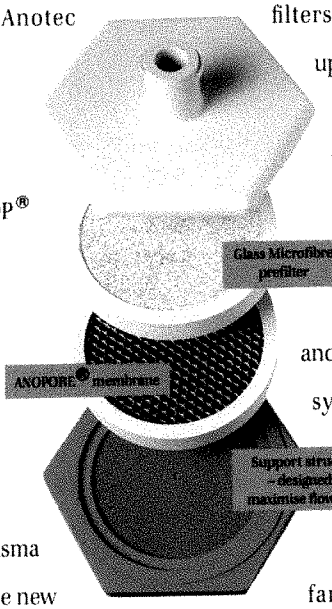


HIGH titre guinea-pig complement is available in bulk from **Serotec.** In its freeze dried state, this product has a long shelf life and, once reconstituted with distilled water, is stable for 1

Cytoscan scoop

THE Cytoscan CS-2 automated chromosome analysis package is at the top of the **Image Recognition Systems** range. It comprises two workstations, one of which can undertake automated screening. Both can be used to locate, select, karyotype and store metaphase spreads. A photographic-quality laser printer provides an immediate copy of the metaphase spread or karyotype. The images can also be stored on disk or tape for future use. Originally developed at MRC's Edinburgh unit, Cytoscan has been further refined by Image Recognition Systems during the past two years to the extent that the company is now the market-leader in this field. *Reader Service No. 542.*

THE ONLY THINGS YOU'LL GET THROUGH OUR FILTERS ARE GOOD RESULTS.



If Mycoplasma infection strikes your plant, cell or tissue cultures it can be disastrous. Death of an experiment, misleading results, in short, hours of wasted time, effort and money.

Fortunately this problem could be a thing of the past. Anotec Separations have introduced the new ANOTOP® PLUS 0.1 micron syringe filter, designed specifically for Mycoplasma removal. The new ANOTOP PLUS is a pre-filter and filter in one compact unit. The glass microfibre pre-filter (which contains no binder) retains particulate matter before the sample passes through the 0.1 micron ANOPORE® membrane for precise filtration. Two stages in one simple step, proven in independent tests to remove up to 99.99% of five of the most common species of Mycoplasma. This eliminates medium contamination ensuring confidence in your results.

The new 0.1 micron ANOTOP PLUS filter is part of Anotec Separations' rapidly expanding range of filters. This includes 0.2 and 0.02 micron ANOTOP PLUS filters for cleaning up samples with heavy particulate loading, the standard range of ANOTOP 10 and 25 disposable syringe filters and the ANODISC™ family of membrane discs. All Anotec Separations' products incorporate the unique ANOPORE inorganic membrane offering well defined retention characteristics, low hold-up volume and wide solvent compatibility.

If you use filters in your laboratory send now for your FREE copy of our catalogue and details of your nearest distributor.

DNA package

AMERSHAM International now supplies *λin vitro* packaging extracts, providing high efficiency of packaging of both wild-type and recombinant DNA. On average 1–2 × 10^9pfu μg^{-1} with wild-type (λ1857Sam7) DNA is achieved. The performance of Amersham's kit is backed up by extensive research in a wide range of cloning vectors and applications, yielding up to 1.5 × 10^9pfu μg^{-1} insert in model cloning experiments. *Reader Service No. 540.*

week at 4°C. It has been lyophilized in the presence of borate-buffered sorbitol (Richardson's) at a *p*H favourable to preserve this titre. Supplied in both 2.0-ml and 5.0-ml volumes for convenience. *Reader Service No. 541.*

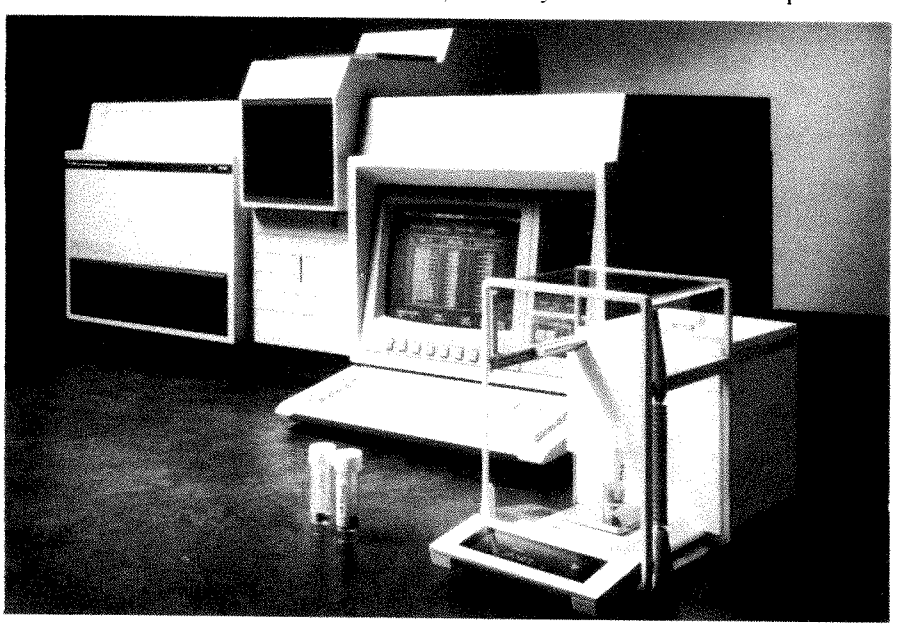
AN extended range of peptide antibodies has been announced by **Cambridge Research Biochemicals.** bR grade antisera from CRB are high quality polyclonal antibodies to biologically active peptides. Antisera are qualified and tested for use for either radioimmunoassay or immunocytochemistry procedures. A number of new antibodies are now available, including antibodies against most neuropeptides, neuroendocrine markers, neurofilaments and a range of hormones. A polyclonal antisera against an HIVgp160/gp41-derived peptide is also available. The range of over 80 bR grade antisera is described in the new 1989 Product Listing available from CRB. *Reader Service No. 539.*

THE cytoskeleton is a complex system of proteins and other molecules integrated to provide the cell structure, motility and internal organization. **Calbiochem** provides antisera to various structural and regulatory components including actin, *a*-actin, ankyrin, keratin, myosin, spectrin, tropomyosin, vimentin and vinculin. All have been evaluated for performance in immunofluorescent assays. *Reader Service No. 538.*

THE HP series of murine monoclonal antibodies specific for human IgG subclasses is now available from **Calbiochem.** These monoclonal antibodies have been applied in the quantitation of the level of each IgG subclass and in the determination of subclasses of human IgG antibodies. They are suitable for other applications, such as subtyping of human IgG myeloma paraprotein with electrophoresis immunofixation. *Reader Service No. 537.*

ENZYMES

A SPECIAL line of tableted enzyme substrates is available from **Sigma.** The horseradish peroxidase substrate 3,3′-diaminobenzidine tetrahydrochloride is now available in tablet form (10mg substrate per tablet) and is suitable for use in immunoblotting and immunohistological staining procedures. 3,3′-diaminobenzidine tetrahydrochloride produces a brown insoluble end-product which can be observed visually. Tablets are packed individually in foil for enhanced stability as well as ease of use and storage. The tablets are sold in 50 or 100 pack sizes with bulk quantities also available. Additional enzyme substrate and buffer tablets are available. *Reader Service No. 536.*



SPECTROMETRY

PHILIPS Analytical has upgraded two of its most popular atomic absorption spectrometers, the PU9200 and PU9400 series, to meet customer requirements. The enhancements mean better all-round AA capability, superior price-performance ratio and improved automation, data handling and ease of use. The PU9100 series has also been upgraded to give higher performance flame, furnace or vapour analysis. *Reader Service No. 535.*

THE FIAS-200 from **Perkin-Elmer** is a high performance flow injection system for atomic spectrometry. It combines the advantages of the mercury/hydride techniques with those of the flow injection technique. With two independently controlled peristaltic pumps for carrier stream, sample and reagents, powerful computer-based electronics and the computer-controlled AS-90 Autosampler the FIAS-200 is ideally suited for use with automatic sequential multi-element AA systems with both FIA-mercury/hydride and FIA-flame techniques. It can also be adapted for use with other applications, such as automatic dilution or the addition of matrix modifiers. *Reader Service No. 534.*

THE **Perkin-Elmer** Model AS-90 Autosampler is a new computer-controlled, multipurpose sampling system for Flame and Flow Injection Atomic Absorption, ICP-AES, ICP-MS and other spectrometric analysis techniques. The AS-90 automates instrument calibration, sample introduction and element program change in the spectrometer via software commands, extending the spectrometer's capabilities to those of a fully automated analytical workstation. It offers large sampling capacity with three removable trays, providing flexibility. *Reader Service No. 533.*

A SUPPLEMENTARY program (slice) is available which permits kinetic analysis using an array of stored spectra generated by **Perkin-Elmer** Computerized

Philips PU9200X/9400X spectrometers feature on-line balance interfacing for full weight and dilution results correction.

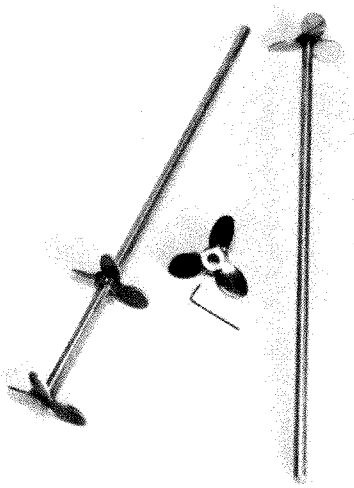
Spectroscopy Software (PECSS). The 2,880 nm min^{-1} scanning speed of the Lambda 2 UV/Vis spectrometer and the PC-based storage facility of PECSS software means that it is possible to optimize wavelengths for kinetic analysis after the data has been collected and also to look at a reaction in terms of both reactants and products. Data output is in either JCAMP, Enzfitter/GraFit* or Lotus (R) 1-2-3 format for data analysis using specialist kinetics programs. *Reader Service No. 532.*

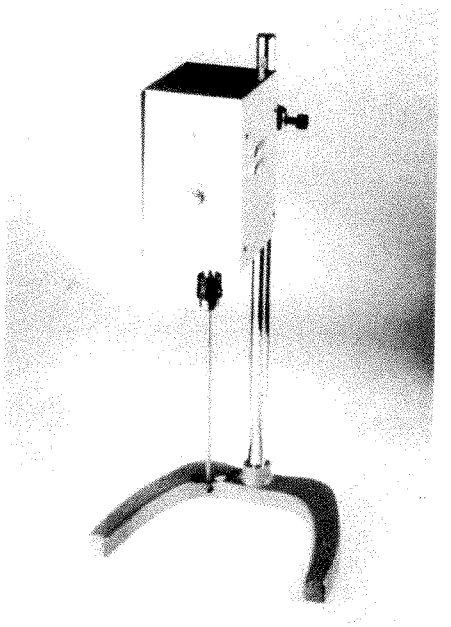


THE latest accessory for **Philips Analytical's** PU8700 UV/Vis spectrophotometer enables melting point (T_m) determinations to be carried out for DNA and other nucleic acid polymers. With Peltier control and a preheater option, Philips PU8764 Temperature Programmer, which fits onto the PU8732 Cell Programmer, can be used in any study where temperature and phase changes are associated with a change in a compound's molar absorptivity. A typical application is the 'fingerprinting' of different DNAs by T_m, which varies according to the GC:AT bond ratio in the double helix. The PU8764 consists of a temperature control unit, and a Peltier-controlled eight-cell holder for up to 10-mm cells or black-walled microcells. Samples can be maintained at a fixed temperature between 0 and 110°C, or heated/cooled at one of four programmed ramp rates. *Reader Service No. 531.*

Service reflected

REFLECTANCE data is often needed by parties lacking the proper equipment to conduct such measurements accurately. **Oriel Labsphere** has established a Reflectance Research Laboratory that can deliver your reflectance data quickly and without the costly investment in equipment, people and facilities. Applications have included measurement of such diverse materials as PC circuit boards for laser etching, reflectance and transmittance of non-hydrated biological samples, metallized coatings on glass, reflectance of fabrics and thin films both at normal incident and at angle through the use of a centre mounted sample holder. Custom fixtures can be constructed to measure almost any sample at least 7 mm in cross-section or of unusual shape. *Reader Service No. 530.*

STIRRERS



INCREASED mixing capacity, together with more efficient stirring is claimed by **Sentinel Laboratories** for their new Power-Stir adjustable impeller. Power-Stir can be attached to any standard impeller having a ¼" diameter shaft. The unit can be used singly or in banks of units to change the stirring patterns within a vessel. The vanes of the impeller are easily adjusted to accommodate different liquid viscosities or particulate matter loads. Use of Power-Stir in opposition to the impeller immediately below can create a more effective flow pattern, and hence more intense mixing. Alternatively, effective

Power-Stir adjustable impeller from Sentinel.

agitation throughout a vessel can take place at lower speeds, thus reducing air entrapment. The Power-Stir impeller is manufactured from high grade stainless steel. *Reader Service No. 529.*

A HIGH-power top-drive stirrer has been introduced by **Sheen Instruments.** The Ultra Mix 3000 is suitable for laboratory, pilot plant and small production unit applications. The unit has continuously variable speed control, in which power phase angle techniques are used to provide high torque at low speeds. Once the operator has set a speed for mixing, this speed will be maintained regardless of changes in sample viscosity. This is achieved by monitoring the motor's back EMF and compensating for any change in load. A safety cut-out operates if the viscosity of the sample being stirred increases beyond the operating range of the drive unit. Ultra Mix 3000 has a

Sheen Instruments Ultra Mix 3000.

speed range of between 300 and 3,000 r.p.m. and a capacity of up to 30 litres. *Reader Service No. 528.*

CLEANSERS

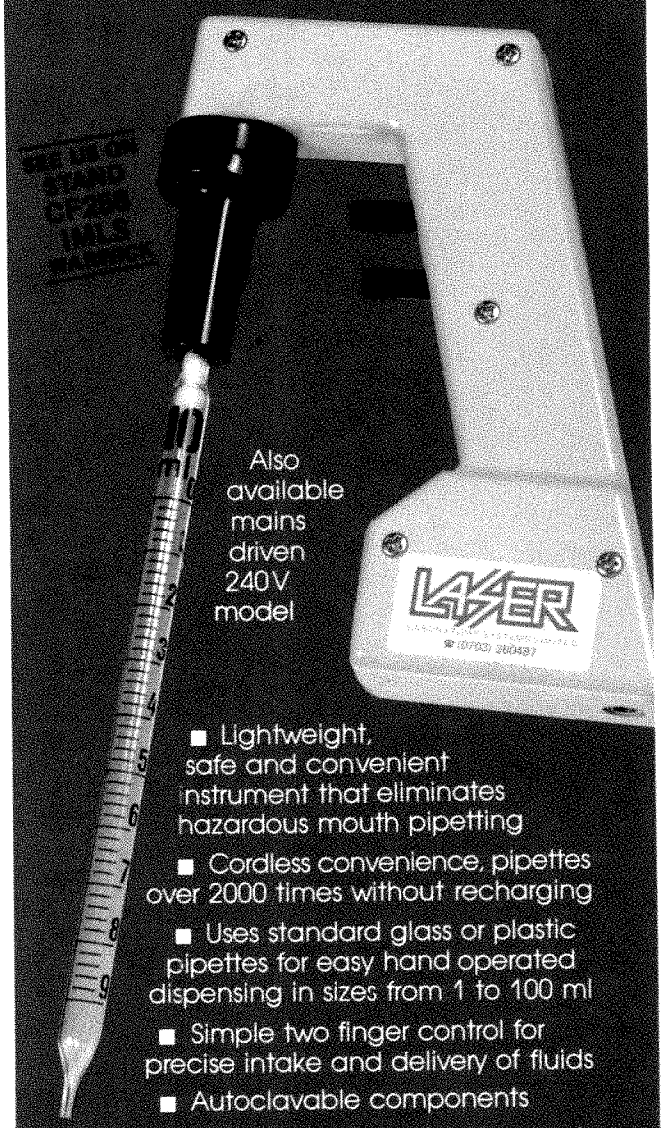
SUR-CROFT is a surface active agent which destroys biological residues on glassware. Developed by **Croft-Greiner** as a laboratory detergent and radioactivity decontaminant, it is relatively inexpensive to use and is phosphate-free and biodegradable as well as being non-toxic and non-corrosive. For normal use a 2.5% solution is all that is required, but where special applications demand it, solutions of up to 50% can be used. *Reader Service No. 527.*

FOR over 10 years, **Calbiochem** has provided a comprehensive line of detergents for use in biochemistry. Many are highly purified to remove the aldehyde and peroxide impurities present in detergents from other sources and all are suitable for use in solubilization of proteins and membranes. The Calbiochem technical monograph *A Guide to the Properties and Uses of Detergents in Biology and Biochemistry* is available free from Novabiochem (UK) Ltd. *Reader Service No. 526.*

A SPECIALLY formulated surfactant from Pierce Chemical Company is on the market from **Life Science Laboratories.** PCC-54 is designed to clean stubborn contaminants from laboratory equipment and apparatus. *Reader Service No. 525.*

MICROLINK
= DATA ACQUISITION

MICROLINK offers the total solution in data acquisition and control with IBM PC, AT and PS/2.
Our NEW 184 page Data Acquisition Catalogue describes our extensive coverage of the field including:



- MICROLINK modular hardware with a range of 60 plug-in modules
- MICROLINK 4000 transient capture system
- MICROLINK software for high and low speed data acquisition
- GPIB interfaces for IBM AT AND PS/2

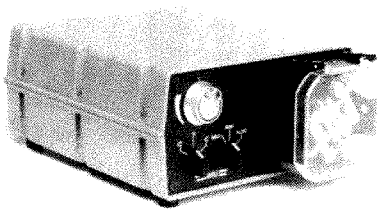
Lynx process

CAMBRIDGE Instruments' **Reichert** division has taken over the sales and servicing of the Lynx Tissue Processor produced by the Australian Biomedical Corporation. The Lynx Processor replaces the labour intensive manual technique for tissue embedding with a compact and reliable system for the automatic processing of biological specimens. The single unit houses the processing and control functions, prepares the specimens from pre-fixation to infiltration in steps ranging from 1 min to 100 h. The temperature is controlled from +4°C to +60°C and the agitation is a 1-mm stroke once per second. Each of the 20 reagent vials can be independently programmed using the membrane keyboard and display. Up to 10 programs can be permanently stored and are protected in the event of a power failure by a battery. *Reader Service No. 514.*

SAMPLE PREPARATION

THE **Reichert** division of Cambridge Instruments has introduced the Super Nova, a new concept in thermal feed ultramicrotomes. The microprocessor control allows a linear advance and permits sectioning to be interrupted and continued without having to re-align the specimen arm. The Super Nova combines modern technology with the high contrast optics of the new Stereozoom 6. Touch-sensitive keys and digital displays on the control panel allow fast section production. An autotrim allows rapid trimming of samples using motor drive and variable manual knife advance. Alignment of knives to the block face (whether glass or diamond) is simplified with the use of the Super Nova's flex-optics approach system and increased cutting forces improve the sectioning characteristics for both semi-thin and ultra-thin sections. The new microscope carrier allows sideways movement of the microscope and it can be tilted in an arc between 12° and 20° from the vertical to ensure optimal illumination for varying water bath levels. *Reader Service No. 513.*

FOR sample preparation in the analytical laboratory, **Severn Analytical** has introduced the CCS Model 3000 system. The CCS Model 3000 is an analytical supercritical fluid extractor accumulator which uses the unique properties of fluids above their critical point to reduce significantly the extraction times required by typical liquid solvent extractions. Components of interest can be selectively extracted and quantitatively accumulated for analysis in a fraction of the time normally required by other solvent extraction techniques. The Model 3000 can be directly coupled to analytical instruments such as GC, HPLC, SFC or the instrument can be operated as an extraction and accumulation device, for collection of extracts for solvent-free analysis by other analytical techniques. The CCS Model 3000 operates under precise microprocessor control. *Reader Service No. 512.*



Sample preparation automated with CCS 3000 System from Severn Analytical.

THE new CDS 300 Sample Concentrator is now available from **Dyson Instruments.** Launched at Pittcon '89 the Model 300 has been designed to meet the needs of the environmental scientist for a low-cost purge and trap instrument. Microprocessor controlled, the Model 300 is easy to use and meets or exceeds all EPA relevant requirements. Up to nine EPA methods may be stored in the instrument's memory. The Model 300 can be optionally configured to perform thermal desorption of air sampling cartridges or soil samples which allows the instrument to perform virtually any EPA analysis for volatile pollutants. It also accepts other options. *Reader Service No. 511.*

PUMPS

THE 504U is a new benchtop peristaltic pump from **Watson-Marlow,** and joins the 604U and 701U pumps manufactured to the IP55 standard. It offers advanced process control facilities and has a gasketed die-cast case, providing IP55 protection for washdown areas and industrial environments. The 504U

Watson-Marlow 504U autocontrol peristaltic pump.

can be controlled by either standard, manual operation or by analogue signals up to 60 V or 32 mA from other instrumentation. Once programmed, the pump provides either rising or falling flow rates against a rising signal. Other pump functions such as speed, direction and stop/start may be externally controlled through the use of a 6-pin connector which outputs analogue tachometer signals. With a choice of six different pumpheads and a speed control ratio of 100:1, the 504U offers flow rates from microlitres through 48 channels to 2.2 l min^{-1} through a single 8.00-mm bore tube. *Reader Service No. 510.*

THE **Jouan** PM600 is an 'intelligent', programmable peristaltic pump. Its 10 non-volatile memory blocks can each contain information on volume, speed and direction of dose. Blocks can be linked with appropriate pauses to provide complex multi-dose programmes. Pumping modes include continuous flow (long term or variable dosing), dose on command or auto repeat dosing. Security modes eliminate spillages. Any volume can be entered without recalibration, after the initial learning phase. This portable unit can dose from 1 ml to several litres with flow rates up to 1.5 l min^{-1} and accuracy and reproducibility better than 1%. *Reader Service No. 509.*

SOFTWARE

A CHROMATOGRAPHY data system, the Model 737, has recently been launched by **Axxiom Chromatography.** The new dual-channel integrator complements the existing Axxiom range — the 727 single-channel data system, and the 747 multi-channel multi-tasking data system. With the 737, a 20-minute HPLC run will reintegrate and redraw in around 2 seconds on an AT compatible computer. New features include the ability to accept signals from two

The popular Uniscience Mini-Gel Electrophoresis System is in a class of its own. Simple, fast and economic.
Insert two buffer/gel end plates, pour your molten agarose, insert a well former and allow your gel to set.
Perfect for DNA and RNA electrophoresis.

- UV transparent
- Complete with 6 well formers (2 each – 4 well, 8 well and 16 well)
- Red stripes at well positions for easy sample loading
- Low reagent usage
- 2 well former positions
- Safety lid with integrated leads
- Compact: Unit is only 120mm × 110mm

NEW KIT

SILVER STAINING – IMPROVED SENSITIVITY IN LESS THAN AN HOUR

7.5% polyacrylamide gels run in 0.025M Tris/Hcl pH 8.4, 0.192M glycine and 0.1% SDS electrode buffer at a constant current of 60 mamp for 1.5 hours. The protein standard samples were prepared in 0.062M Tris/Hcl pH 6.8, 2% SDS, 10% glycerol, 5% 2-mercaptoethanol and 0.001% bromophenol blue, loading buffer, producing the following concentration of protein per band: 1). 2 ug 2). 1 ug, 3). 500 ng 4). 100 ng, 5). 20 ng, 6). 5 ng, 7). 1 ng, 8). 500 pg, 9). 100 pg 10). 5 pg.

IT'S YOURS WITH KOCH-LIGHT'S NEW SILVER STAIN KIT

The protein gel (above left) was stained overnight with Coomassie Brilliant Blue (CBB) – 4 lanes are clearly visible. The identical gel on the right was stained for one hour with Koch-Light's SILVER STAIN KIT – 7 lanes are clearly visible.

These typical results show that with Koch-Light's SILVER STAIN KIT:

- Sensitivity is increased over one hundred fold compared to CBB
- Results are obtained in an hour, not the next day.

So if you want to detect nanogram quantities of protein, the Koch-Light SILVER STAIN KIT provides you with the most rapid and sensitive system available.

Full details on the Silver Stain, as well as the rest of the Molecular Biology/Biochemical range, are available from Koch-Light or your local New Brunswick Scientific Company.

gas or liquid chromatographs, whilst simultaneously displaying all the signals on the screen. There is also optional pump control of two ternary HPLC systems. Contact closures and external relays supplied as standard allow the system to be interfaced with auto-samplers or switching valves. The Model 737 may also be upgraded to the 747. *Reader Service No. 508.*

A NEW chromatography data handling system has been launched by **Severn Analytical.** The Apex Chromatography Data System is a PC-compatible integration system designed for gas and liquid chromatographers. The system allows the user to utilize his PC for other tasks such as word processing and spreadsheet analysis whilst collecting chromatographic data. It is available as a single, four-channel, or 15-channel system, all channels are able to accept up to four detector inputs. The in-built Help facilities available when setting up methods and reprocessing chromatograms make Apex easier to use. Depending on the user's preference the system can be operated either via the keyboard or from the mouse. Standard features include multi-level calibration with on-screen display of the calibration curve. *Reader Service No. 507.*

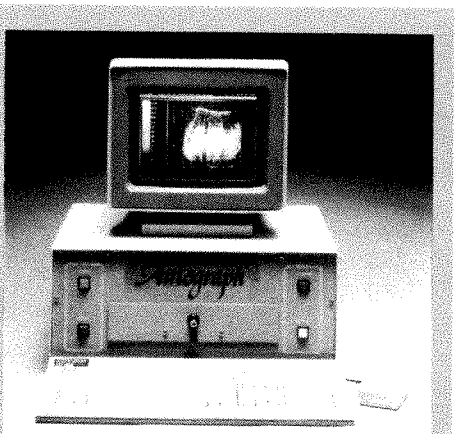
Apex chromatography analysis.

PERKIN-ELMER has introduced PC software for multicomponent quantitative analysis based on infrared (IR), ultraviolet (UV) or fluorescence (FL) spectra. PC Quant uses full spectra to calibrate and analyse up to 15 components in a single step. It runs under the control of IR, UV or FL Data Manager packages on the IBM (R) PS/2 or Epson (TM) computers. *Reader Service No. 506.*

Information is shown in a multitude of forms on Scan Analysis from Biosoft.

SCAN Analysis, a new software package for the Apple Mackintosh from **Biosoft,** uses ThunderScan scanner, MacVision and QuickCapture video digitizers or greyscale scanners to acquire images. It will integrate user-selected regions on polyacrylamide and Agarose gels, autoradiograms, TLC plates or any other material that can be scanned. Scan Analysis has both automatic peak-sensing and manual integration modes. Multiple background subtraction modes include tangent skim and group-interpolated. There is full control over the way the selection is integrated including data smoothing. *Reader Service No. 505.*

ALSO from **Biosoft** is Gelsim, a gel electrophoresis simulation and analysis package. When presented with a set of experimental conditions, Gelsim performs simulated electrophoresis. It also helps analyse results of experiments. Gel summary sheets may be printed, and hard copies of gel and banding patterns may be made in a variety of sizes and resolutions. *Reader Service No. 504.*

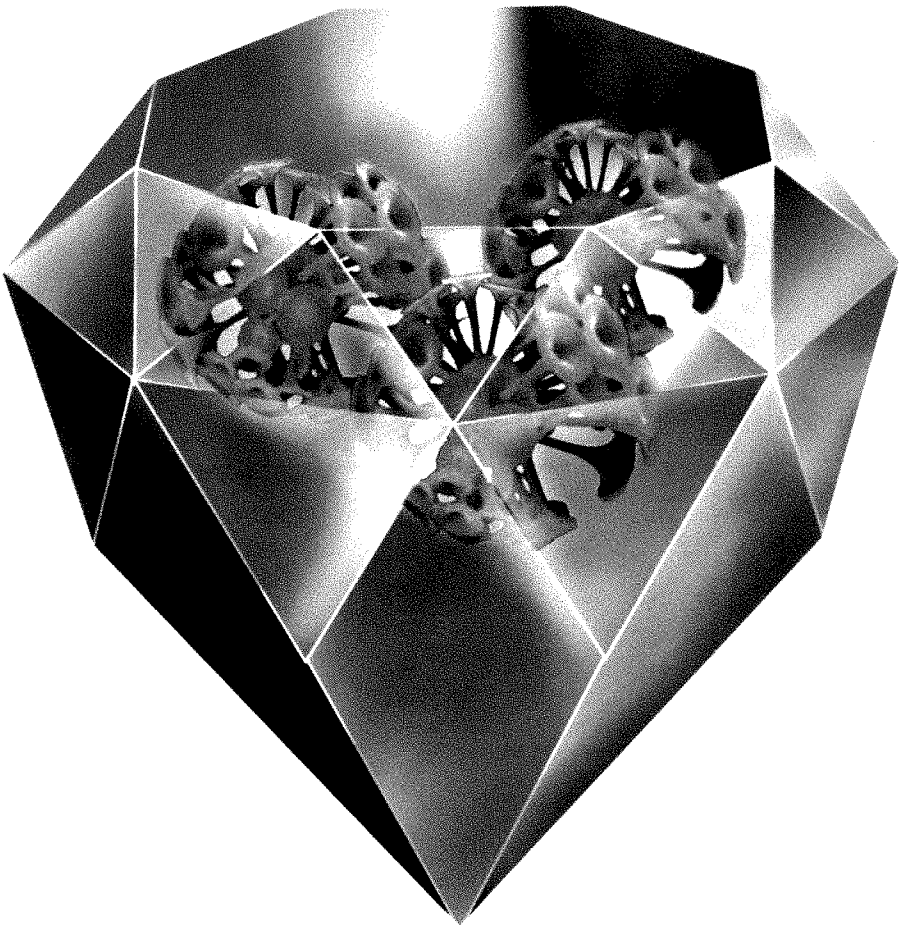


DISINTEGRATORS

ADDITIONAL sound-proofing ensures that the powerful ultrasound output generated by the **MSE** Soniprep 150 is contained within the instrument. The Soniprep 150 can therefore be operated comfortably in the laboratory environment. Automatic feedback control of the 23 kHz generator allows optimal excitation of the piezo-electric transducer to be maintained consistently and the Soniprep's amplitude meter affords good reproducibility of sonication conditions. During operation, the sample remains visible through the transparent door and the standard unit incorporates a timer. For programmable control of sonication/cooling cycles, the Soniprep 150 can be supplied with a process timer unit. *Reader Service No. 502.*

HOMOGENIZER

A HAND-HELD rechargeable homogenizer, the Omni International 1000, is now offered by **Camlab.** Designed for microprocessing from 0.1 to 100ml it has a two speed high-torque motor (15,000/20,000 r.p.m.). This and the choice of three different size autoclavable rotor-stator generators make the Omni 1000 a versatile portable homogenizer. The Omni 1000 is available with the choice of either a 5-mm diameter mini-micro (0.1-5.0ml capacity), 7-mm diameter micro generator (0.25-10ml capacity) or 10-mm diameter macro generator (1.5-100ml capacity). *Reader Service No. 502.*



Finding fingerprints

A BREAKTHROUGH in fingerprinting techniques has been announced by **Saxon Micro.** 'Autograph' is the company's new process for digitally imaging and evaluating radioisotope labels. 'Autograph' is suitable for use in chromatography, gels, blots, tissue sections and similar samples. A new digital collimator has been adapted by Saxon so it is able to form an image 50 or more times faster than film, says the company. Thus experimental data can be provided in minutes. A 1-mm resolution is provided over an image window of 220 × 220 mm. Computer imaging and software, and display capabilities combined with low background counts provide the ability to resolve more shades of 'grey' than film. *Reader Service No. 503.*

SAPPHIRE

all image processors are not the same

and noise reduction is only part of the story

Most systems available today begin with noise reduction – and that's where the image processing ends.

Now Sapphire takes over, with analogue gamma correction to optimise the input signal: with unique **Real-time** digital shading correction and with histogram equalisation facilities, compensating for uneven illumination or high profile subjects. **And** it has the most rapid and sophisticated noise reduction in the business.

It's not simply a pursuit of clever processing which defines Sapphire, but cool headed economic performance. The new shading-correction capability alone s gnificantly extends the useful life of camera and intensifier by compensating for wear.

Just one of the ways that Sapphire pays for itself, time and again.

Sapphire deserves a closer look – call us now for the full picture or use the reply number for rapid response.

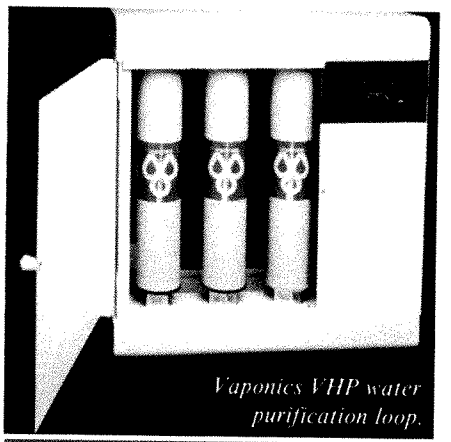
ELECTROPHORESIS

NEW Horizon 11:14 and 20:25 electrophoresis systems are available from **Gibco BRL**. The systems are available in 11 × 14cm and 20 × 25cm gel sizes and are designed to maximize user safety, featuring safety interlock lids and shrouded power cords. Drop-in dams simplify gel casting and a removable UV transparent gel tray lets you monitor gels during electrophoresis. Multiple comb slots allow you to double the number of samples per gel and red well visualization strips make sample loading easier, while the black graduations permit accurate monitoring of the gel during electrophoresis. The systems have no-leak, quick-connect buffer points for buffer recirculation and moulded buffer pouring spouts for easy buffer disposal. *Reader Service No. 501.*

FOR researchers using capillary zone electrophoresis, **Severn Analytical** has designed a new flow cell. This new flow cell has an internal volume of 35 nanolitres and a 0.5 mm pathlength. It will fit any of Severn's existing 6000 series variable and programmable UV/Vis detectors, including the SA6500, SA6503, SA6504 and the new Rapiscan SA6508 detector. All the flow cells in the range available from Severn Analytical are easily interchangeable and require no alignment. Cells can be changed quickly and allow the chemist to explore a variety of chromatographic techniques using a single instrument. *Reader Service No. 500.*

Synergists

BOTH **Perkin-Elmer** and **Applied Biosystems** are cooperating in the promotion of Perkin-Elmer Cetus' DNA Thermal Cycler and GeneAmp Amplification Reagents and Applied Biosystems' newly announced PCR MATE DNA Synthesizer. ABI now has licence to promote and support the use of PCR MATE for the synthesis of DNA primers for the polymerase chain reaction technique. Perkin-Elmer Cetus will market complementary DNA amplification products to the PCR MATE customer base. This cooperative marketing programme is anticipated to increase the research community's access to automated instrumentation and reagents. *Reader Service No. 495.*



Ultra-Violet Products has a new video system for DNA electrophoresis gels.

DOCUMENTATION of DNA electrophoresis gels has been simplified with a new video system from **Ultra-Violet Products.** The camera has been specifically developed for the photography of low-light fluorescent patterns, such as ethidium bromide (EB) stained DNA gels. The desired image is selected by moving the camera up or down on its stand and a video monitor is used to check the image focus. Exposure times are controlled by two push-buttons and range from 0.03 to 16 seconds. A hard copy of the image is produced on thermal paper by a high resolution printer in as little as 10 seconds. Additional information is printed on a data line above the image. When the camera system is being used for photographing gels it comprises a thermo-electrically cooled CCD-camera, an optics and control unit, a 9" video monitor, a video printer, a stand and a UV transilluminator (302 nm) with filter, together with an interference filter for DNA gels. *Reader Service No. 499.*

THE latest technology for gel drying is now available from **Biotech Instruments.** The Pulsdry 100, which uses microwaves to dry gels gently and thoroughly, is the latest addition to Biotech's 'Biogel' range of electrophoresis equipment and accessories. The Biogel Pulsdry 100 is designed to dry both Agarose and polyacrylamide gels quickly, evenly and completely. Up to three gels, with up to 1,200 cm^2 total surface area, may be processed simultaneously. Microwave drying is both efficient and versatile. As well as gel drying, the Pulsdry 100 can be used to heat liquids, melt Agarose and perform many other routine laboratory procedures where precise heating is required. A special accessory uses internally generated heat and reduced pressure to dehydrate gels and fix them to storage or processing media. *Reader Service No. 498.*

WATER PURIFIERS

THE **Vaponics** VHP Series Water Purification Loop is a cabinet-enclosed laboratory system containing pre-treatment, polishing and filtration cartridges to remove contaminants as required by the application of the processed water. With feedwater, the VHP system will produce water capable of exceeding CAP, NCCLS and ASTM standards for Type 1 reagent grade water. Two sizes are available, offering three and four cartridge systems with flows of up to 4 l min^{-1}. The patent quick disconnect cartridge holder features an 'O' ring seating for easy installation and removal of disposable cartridges. Continuous recirculation of water maintains product purity. *Reader Service No. 497.*

Vaponics VHP water purification loop.

REAGENTS

FLUORESCENT and enzyme conjugates of ultrapure streptavidin are available from **Vector Laboratories** for use in immunohistochemistry, enzyme immunoassays, cell sorting or transfer blot applications. Each of these conjugates has been optimally labelled and thoroughly tested to ensure maximal performance. Fluorescently-labelled ultrapure streptavidin, with a choice of fluorescein, Texas Red, phycoerythrin or AMCA (coumarin), a new blue fluorescent dye, provides a detection reagent for use in flow cytometry, *in situ* hybridization, chromosomal mapping and fluorescent microscopy. Enzyme-conjugated streptavidin is available with either peroxidase or alkaline phosphatase as the label. These can be used in Western, Northern, Southern, dot or slot blot techniques, in enzyme immunoassays, or in immunohistochemical applications. Ultrapure streptavidin is also offered in unconjugated form. *Reader Service No. 496.*

DESIGNED for use with the **Applied Biosystems** 370A DNA Sequencer, the new Taq polymerase reagent kit simplifies the preparation of extension products for automated DNA sequencing using fluorescent-based technology. With its unique thermophilic properties, Taq polymerase offers benefits not available with other enzymes such as Klenow, modified T7 and reverse transcriptase. Longer runs can be obtained, for example, 500 bases per sequencing reaction at greater than 99% accuracy even with GC-rich or palindromic samples. Additional advantages include more uniform band intensities, lower background and a requirement of less than 1 μg of starting template. Developed in conjunction with Promega, the kit includes all reagents necessary for 100 enzymatic determinations. The reagents are supplied pre-mixed in 1.5-ml microcentrifuge tubes, with each tube colour-coded for the corresponding nucleotide. *Reader Service No. 494.*

NEW technologies in non-isotopic gene probes, automated DNA sequencing and antisense oligonucleotide technology have created the need to label oligonucleotides. **Cruachem** has introduced a range of DNA modification reagents for functionalizing oligonucleotides with a reactive amine group at any position in the oligonucleotide. Included in the range is a ThiolModifier which attaches at the 5′ position and a reagent for chemically phosphorylating the 5′ terminus of the oligonucleotide. 'Easy Label' kits are designed non-isotopically to label synthetic oligonucleotides at the 5′ or the 3′ end with biotin or fluorescein. The kits include all the reagents necessary. *Reader Service No. 493.*

PEPTIDE SYNTHESIS

A DEVELOPMENT in peptide synthesis that provides a novel method for detecting reaction rates in solid state peptide syntheses has been announced by **Biotech Instruments.** The new sensor provides a simple, non-destructive means of monitoring the progress of synthesis reactions and determining when they are complete. Biotech's new Conductivity Sensor is relatively insensitive to reactant concentration. The method provides accurate kinetic data on any scale of synthesis which can be used to predict the expected extent of the reaction. *Reader Service No. 492.*

MICROSCOPY

CUE MS from Olympus features joystick and manual control options.

THE **Olympus** CUE MS is a purpose-built *xy* stage featuring the option of joystick motorized control and onstage manual control. Used in conjunction with the Olympus microscope controller, the CUE MS joystick control features variable speed from 50 to 5,000 μm. Direct drive stepping motors eliminate backlash and with a focus resolution of 0.5 μm provide precise and accurate operation. When coupled to one of the CUE series image analysers with appropriate software, a movement sequence can be programmed for any given slide. The manual control facility from the stage is useful when looking down the microscope or operating a keyboard. *Reader Service No. 491.*

SCIENTISTS and technicians at **Carl Zeiss** have developed a complete series of new laser scan microscope systems. The company can now offer 'tailor-made', application-orientated instruments for critical tasks in the life sciences, the semiconductor industry and the material sciences. The second generation laser scan microscopes are now equipped with the new Zeiss ICS optics (Infinity Colour-Corrected System). The optical system has been newly computed from the laser light source to the detector. The result is improvement in the optical performance of the system which, when combined with the electronics, provides better quality microscopic images and greater information content. All variants of the LSM microscope systems offer the possibility of 'confocal' laser scan microscopy. This technique images exactly defined horizontal layers of the specimen and is therefore capable of recognizing visible height differences of less than 0.1 μm. A top-quality image is obtained when images of several layers are superimposed. *Reader Service No. 490.*

pH METERS

RUSSELL pH has launched a new high-temperature, *p*H electrode. Designed for use where steam-sterilization is involved to destroy all microorganisms, this new electrode has been shown to withstand multiple autoclavings. The combined *p*H probe is not only able to withstand pressure and temperature without loss of prior buffer calibration but is able to measure continuously for periods of up to several days at 25-35°C. *p*H measurement is of prime importance when growing lower organisms. *Reader Service No. 489.*

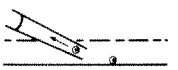
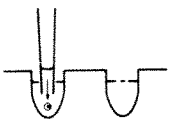
Introducing...



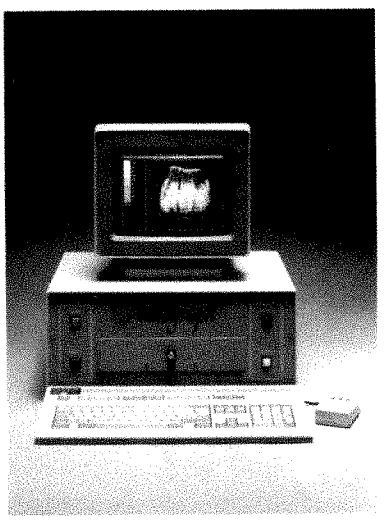
QUIXELL CELL TRANSFER SYSTEM

► ***QUIXELL*** is a revolutionary new system for the rapid collection and transfer of individual cells, clones and other organisms from one vessel to another. The unique positive displacement micro pipette makes possible the controlled collection of a cell while remaining under full observation. a single collect/transfer operation takes only seconds allowing a microtiter tray to be rapidly seeded with individual cells. A wide range of pipette diameters are available to suit multiple applications.



The joystick control is used to guide a cell towards the tip of the pipette,

the cell is drawn into the pipette,



and a single keypress transfers the cell to a well in the microtiter tray. The system is now ready to collect the next cell.

Introducing...

Autograph RADIO ISOTOPE IMAGING SYSTEM

► ***AUTOGRAPH*** represents a breakthrough in digital imaging technology for the rapid evaluation of radio-isotope labels in chromatography gels, blots, tissue sections and similar samples.
The system is able to form an image at least fifty times faster than film thus providing conclusive experimental data in minutes rather than days or weeks. Extensive computer imaging software and display capabilities combined with extremely low background counts provide the capability of resolving many more 'shades of grey' than film making it possible to resolve even the weakest of radio-isotope concentrations.
All software is personal computer based and operates with a user friendly 'pull down' menu environment. Further applications software provides full quantification facilities for even the most complex images.

Developed and manufactured by Oxford Positron Systems Ltd.

Technical Specifications

- Live area : 210 mm x 210 mm
- Spatial Resolution : 1 mm
- Sensitivity :
  19 dpm in sq cm of ^{14}C in 6 min
  Background : 1.7 cpm per cm^2
- Chamber gas:
- Argon 95%, Carbon Dioxide 4%, Isobutane 1%
  Isotopes: ^{32}P ^{35}S ^{14}C ^{125}I. . . .

Software Specifications

- 256 colour display
- Simple user interface based on pull-down menus
- Continuous on-line image formation
- Scaling linear, log, automatic, or user defined
- Automatic user background correction
- Specimen Formats:
  Southern, Northern blots, Dot blots, Microtitre places, tissue sections, TLC plates. . . .
- 1-D or 2-D quantitation, displays and hard copy output
- User defined area, line and point quantification
- Further applications software available.

TEST TUBES
RACKS · MIXERS · ROLLERS
ORBITAL SHAKERS
INCUBATOR SHAKERS
& A RANGE OF DISPOSABLES

Luckham has the lot

Luckham – the laboratory equipment and disposables specialist – has a lot to offer the busy labware purchaser. A complete range of top quality products, from sophisticated test instruments to competitively priced disposables, all available FAST from stock. No need to "shop around". For value and choice, contact Luckham for full details of a range that includes:

- Suspension and Cell Mixers
- Rocking Tables
- Multimix Rollers
- Orbital Shakers
- Incubation Shakers
- Test Tubes and Racks
- Freezer Files
- Gloves, Tape and Bubble Tubing

PROGRAMMABLE THERMAL CONTROLLER

Unique Peltier driven, electronic heat pump coupled to easy to use microprocessor programmer, provides superb temperature control without the use of refrigeration or water circulation.

* Temperature range 0°C to 100°C
* Rate in excess of 50°C either way.
* Accurate ± 0.5°C, no overshoot.
* Accepts up to 50 individual programmes, recalled by descriptive names.
* Will step temperature, slope temperature, time and cycle temperature up to 10,000 times.
* Final step can hold samples at +4°C indefinitely.
* No moving parts, very reliable and maintenance free.
* Available as a 96 well microtitre block option or to accept 60 x 0.5 ml eppendorf tubes.
* Uniform temperature distribution over block.

This must be the most compact, versatile, easy to use programmable thermal controller available, competitively priced at £2650.00 complete.

Further details or a demonstration available from Genetic Research Instrumentation.

LITERATURE

A *Medical & Diagnostics Products Catalogue* is now available free from **LEP Scientific.** The catalogue contains details of reagents, test kits, controls and antibodies for use in haemostasis, cytochemistry, haematology, immunology and blood group serology. The complete range of reagents and controls for the TOA-Sysmex range of blood cell analysers is included, as well as a wide range of universal stains and standards and the wide range of Bio/Data Haemostasis reagents, controls and calibration materials. Amongst the cytochemistry range of products is a unique and more specific cytochemical technique for the detection of the malarial parasite in peripheral blood. The new technique is quicker than the more usual Romanowsky or related techniques and is suitable for mass production screening or for the diagnostic service laboratory. *Reader Service No. 524.*

A NEW chromatography columns catalogue, *Liquid Chromatography Separations,* has been released by **Anachem.** With self-prompting contents and each separation indexed by molecule, the catalogue provides accessible separations information for liquid chromatographers. Columns for analytical HPLC, preparative HPLC and biopolymer chromatography are listed and fully explained. The HPLC column range includes Dynamax, Spherisorb, Partisil, Brownlee, Zorbax, Anagel-TSK, Hamilton, Mitsui and Zeta products and glass columns for low pressure gel chromatography. *Reader Service No. 523.*

A LEAFLET, available from **Coulter Electronics,** reviews complete cell analysis (CCA). This innovative concept integrates Coulter's automated technology — haematology, immunology and flow cytometry — and offers the potential to diagnose diseases of the blood in only 10 minutes. *Reader Service No. 522.*

THE 1989 **Sigma** Radiochemicals Catalogue contains an expanded list of biochemicals, including carbon-14 labelled amino acids, carbohydrates, methylated proteins and molecular weight markers and tritium labelled nucleotides. Also listed are carbon-14 labelled organics including pesticides. *Reader Service No. 521.*

A CATALOGUE describing their equipment for down-stream processing in the Biotechnology industry has been published by **Life Science Laboratories.** It details the principles that have evolved to optimize the separation and purification of biological materials on laboratory, pilot and production scales and describes the equipment that today forms the LSL Midas range of advanced cross-flow filtration products. A wide range of membrane materials provide solutions for the separation of most biological products and each type of membrane is available in a range of scaled modules for development of new processes. For sterile processing, LSL recently announced the Carbosep membrane; a new concept which allows steam sterilization, repeated decontamination and pumped operation at up to 15 bar. *Reader Service No. 520.*

A BROCHURE featuring the two microdialyzer Systems from Pierce has been released by **Life Science Laboratories.** The brochure details the problems associated with small sample dialysis, and the benefits of using the Pierce Microdialyzer for these applications. The two systems described in the brochure both allow simulaneous dialysis of multiple small sample volumes with times typically less than one hour. Both incorporate features that maximize dialysis efficiency for volumes from 20 to 50μl. *Reader Service No. 519.*

Cell line mine

THE **European Collection of Animal Cell Cultures** (ECACC) based at the Public Health Laboratory Service, Centre for Applied Microbiology & Research, Porton Down, has been operational since 1984 and is currently undergoing rapid expansion to double the size of laboratories in the next year. Updates of its general catalogues of cell lines and hybridomas available from the collection and two specialist catalogues, one of HLA-defined β-lymphoblastoid cell lines and another of β-lymphoblastoid cell lines derived from patients with human genetic disorders, are now available. An entirely new venture for the expanded collection is the supply of DNA probes. The ECACC also provides a range of quality control services for the biotechnology industry. *Reader Service No. 518.*

A CYANOBACTERIUM ECONOMICAL WITH THE SULPHUR

SCIENTIFIC INSTRUMENTATION
product review

If the moon can move oceans, imagine what it can do to formulations.

METTLER AT with FACT puts you in control.

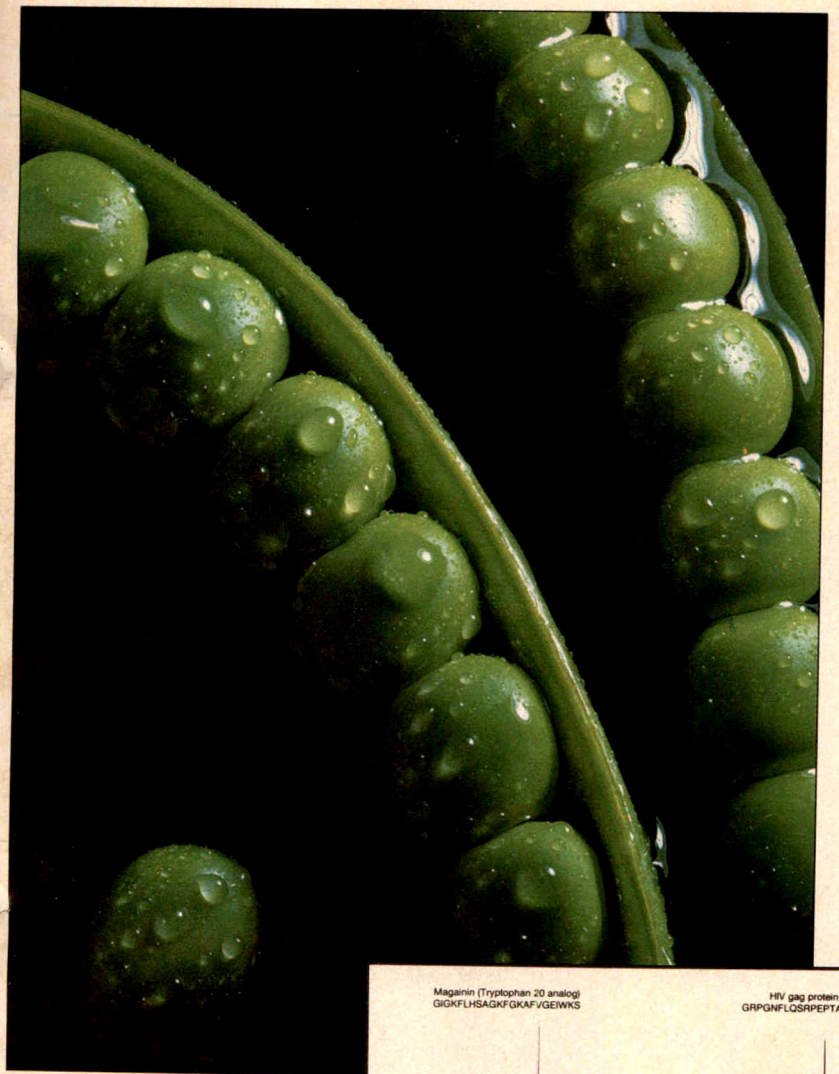
When you consider the gravity of the situation, you'll be glad to know the METTLER AT has the power to do something about it.

As a matter of FACT (that's Fully Automatic Calibration Technology), it does everything in its power to combat the forces of nature.

FACT gives the AT Analytical Balance a mind of its own. It actually adjusts itself to the unsettling influences of gravity, temperature and humidity. So no matter where in the world you use the AT, you get the absolute precision you expect from a METTLER instrument.

What's more, FACT even decides when a calibration is needed. And does it at your convenience. Automatically.

When it comes to controlling the elements of your lab's environment, there's never been a more natural way.



To find out more, call us.

METTLER

Reader Service No.335

We specialize in quality, custom peptide synthesis . . . so *you* don't have to!

HPLCs of unpurified, HF cleaved peptides

Our proprietary techniques enable MPS to supply you with all the custom peptides you need. For example, we can provide over 100 completely different 15-residue peptides in as little as three weeks. An analytical HPLC chromatogram is included with each peptide ordered.

MPS offers quality peptides with service we're sure you'll like. Call us with your questions or if you would like a complete price list.

MPS also provides a custom HF Cleavage Service and a unique HF Cleavage System.

COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

10mer	**$400**
15mer	**$550**
20mer	**$800**

Prices are based on 50mg of HF Cleaved Peptide. 4 to 6 weeks delivery, minimum order of 3 peptides or $1000.

CAN YOU SYNTHESIZE PEPTIDES FOR LESS?

Before you buy an automated peptide synthesizer, you should consider the actual cost for in-house synthesis which includes the cost of reagants, personnel, service contracts, analysis, waste disposal, downtime and, of course, the initial cost of the synthesizer.

RESEARCH IN CELL CONTROL

MORE THAN A REMOTE POSSIBILITY

To keep your finger on the button in cellular control a wide range of Cytokine products is now available from British Bio-technology.

Designer Genes™, Designer Probes™, Proteins and Antibodies - tools to help you progress in your research.

Designer Genes™

Two types of Designer Gene ™ are available - fully designed genes can be expressed in *E. coli* whilst their natural counterparts may be expressed in eukaryotic systems or used as hybridisation probes.

Designer Genes
- all supplied as 10 ug lyophilised plasmid DNA

Human IL-1α	Human TNFβ
Human IL-1α (nat)	Human TNFβ (nat)
Human IL-1β	Human G-CSF
Human IL-1β (nat)	Human GM-CSF
Human IL-2	Murine GM-CSF
Human IL-2 (nat)	Human Acidic FGF
Human IL-3	Human Basic FGF
Murine IL-3	Human TGFα
Human IL-4	Human TGFβ$_1$
Murine IL-4	Human EGF
Human IL-5	Human βECGF
Human IL-6	Human IGF I
Murine IL-6	Human IGF II
Human IL-7	Human PDGF A Chain
Murine IL-7	Human PDGF B Chain
Human IL-8	Human IFNγ
Human TNFα	Human NGFβ
Human TNFα (nat)	Human Angiogenin

Quality control and protocol data is available.

Designer Probes ™

Designer Probes to Cytokines and Growth Factors are available as exon-specific probes or as Probe Cocktails which maximise sensitivity.

All probes are single stranded, of defined

length and sequence, and are suitable for Northern and Southern hybridisation, *in-situ* hybridisation and colony, plaque and dot blot hybridisation techniques.

Designer Probes
- All supplied as 1 ug lyophilised DNA

Human IL-1α	Human GM-CSF
Human IL-1β	Human TNFα
Human IL-2	Human TNFβ
Human IL-3	Human PDGF A
Human IL-4	Human PDGF B
Human IL-5	Human TGFβ_1
Human IL-6	Human Acidic FGF
Human G-CSF	Human Basic FGF

MURINE COUNTERPARTS TO ABOVE GENES AND PROBES WILL BE AVAILABLE SOON, please enquire for further details.

Proteins

British Bio-technology now have available a wide range of natural and recombinant Cytokine and growth factor proteins. The range is continually expanding - please enquire if your Cytokine of interest is not listed.

Natural Cytokines - range of pack sizes available	**Recombinant Cytokines**
Human TGFβ_1	Human IL-1α
Porcine TGFβ_1	Human IL-1β
Porcine TGFβ_2	Human IL-2
Porcine TGF$\beta_{1.2}$	Human IL-3
Human PDGF	Human IL-4
Porcine PDGF	Human IL-6
Bovine Acidic FGF	Human TNFα
Bovine Basic FGF	Human TNFβ

Cytokine Sampler Kit - sample sized quantities of the recombinant proteins available for initial testing purposes.

Antibodies

British Bio-technology has available a range of antibodies to detect the proteins and to neutralise the biological activity of the Cytokines.

Polyclonal Neutralising Antibodies

anti-Human IL-1α	anti-Human TNFβ
anti-Human IL-1β	anti-Human GM-CSF
anti-Human IL-2	anti-Porcine TGFβ
anti-Human IL-3	anti-Human PDGF
anti-Human IL-4	anti-Porcine PDGF
anti-Human IL-6	anti-Bovine Basic FGF
anti-Human TNFα	anti-Bovine Acidic FGF

Polyclonal Detection Antibodies	**Polyclonal Detection Kit**
anti-Porcine TGFβ	anti-Porcine TGFβ

Our range of antibodies is expanding rapidly as more Cytokine proteins become available for use as antigens, please contact British Bio-technology for further details.

BRITISH BIO-TECHNOLOGY - KEEPING YOU IN THE PICTURE WITH CYTOKINE RESEARCH

In the USA and Canada contact R & D Systems - Minneapolis 1-800-328-2400 for all products except Designer Genes.™ Please contact us for details of other local distributors.

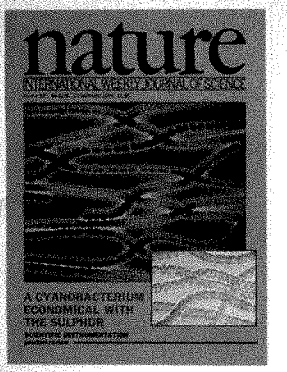
Safety by design

New packaging for ^{32}P-nucleotides

Amersham introduces new packaging for its range of ^{32}P-labelled nucleotides. The new custom designed container (CDC) has been designed in response to customer feedback and achieves the two most important features, *optimum safety* and *ease of use.*

- **Improved shielding** – The new CDC contains both lead and transparent plastic to provide comprehensive shielding.
- **Easy access** – The new container can be opened easily by merely unscrewing the tightly sealed lid.
- **Convenient handling** – The inner vial can be transferred to other specially designed, transparent containers for ease of pipetting while completely shielding the user from β-radiation.
- **Rapid thawing** – By transferring the inner vial to the specially designed holder or workstation, thawing times are reduced by more than half.



For further information about the new packaging and the full range of Amersham's labelled nucleotides, contact your Amersham representative or your local Amersham office.

nature

21 September 1989

Vol. 341 Issue no. 6239

◀ The cyanobacterium *Calothrix* has an extra set of genes for its major light-harvesting proteins that are induced under conditions of sulphur limitation, and which are depleted in the sulphur-containing amino acids. Filaments appear green in sulphur-restricted growth, and brown 'normally'. Page 245.

THIS WEEK

Alzheimer's protein

Beta A4 protein, a precursor of the amyloid protein that accumulates in the brain in Alzheimer's disease, can be picked up serologically in other tissues. This finding may have diagnostic application, and raises the possibility that a circulating protein may account for abnormalities associated with the disease. Page 226.

Night moves

Very-low-frequency (VLF) electric field bursts observed on the nightside of Venus are commonly assumed to be evidence for lightning. But another explanation is put forward on page 219; the bursts may be analogous to another terrestrial phenomenon, the VLF 'saucer'-type emissions seen over the polar ionosphere.

Hives of activity

The misidentification of 'yellow rain' as a biological warfare agent drew attention to the phenomenon, in fact caused by defaecation during massed flights of the giant honeybee. To date no explanation for this behaviour has gained general acceptance: on page 191 a new one is offered, based on the need to prevent the temperature of bees' nests becoming so hot as to endanger the larvae.

Sides of Schrödinger

Erwin Schrödinger has a prominent place in the pantheon of physics. But darker sides of his life emerge from a new biography. Book Reviews, page 193.

Inositol phospholipid

Inositol phospholipids are second messengers that, among other things, control the release of intracellular calcium. Models for the generation of the calcium signal, which seems to be periodic, are reviewed by M. J. Berridge and R. F. Irvine on page 197.

Import business

A membrane protein necessary for importing proteins into mitochondria has been identified by photo-crosslinking with a chimaeric protein that jams in the import machinery. Page 205

Accurate *ras* structure

The crystal structure of the guanine nucleotide-binding domain of *ras* oncogene, at 2.6Å resolution, shows similarities to the nucleotide-binding domain of bacterial elongation factor EF-Tu. Page 209.

Making better polymers

Immiscible polymers may be bound together by 'diblock copolymer' chains for which half of each chain is soluble in the respective polymers. Work described on page 221 shows how the block copolymers align at the interface, thus stitching the bulk polymers together. Information is also gained about how the polymers fracture, which could be useful for improving the mechanical properties of polymer blends.

Lambda integration

A specific cellular protein is required for site-specific integration of phage lambda into the chromosome of its host, *E. coli*. Direct evidence has now been obtained that DNA-bending is the important part played by the protein in lambda integration, page 251. On page 255 the phase relationship of the integration host factor-induced bends is reported. See also News and Views, page 184.

Little boxes

A 'concensus' homoeobox probe detects 60 sequences in the genome of the nematode *C. elegans*, suggesting that, like flies and vertebrates, it may contain many homoeogenes. Page 239.
